Chlor-substitution products of the saturated paraffin hydrocarbons; Preparation of —. C. Blanc, Assignor to The Goodyear Tire and Rubber Co., Akron, Ohio. U.S. Pat. 1,248,065, Nov. 27, 1917. Date of appl., May 1, 1914.

A LIQUID paraffin hydrocarbon is subjected to the action of chlorine and a chlorine carrier under the influence of actinic light and a temperature-regulating agent. The desired chlorine substitution product is removed and fresh supplies of chlorine and hydrocarbon added to the remaining material.—L. A. C.

[Aromatic] alcohols; Process of producing — by hydrogenation. A. Brochet. Paris. U.S. Pat. 1,247,629, Nov. 27, 1917. Date of appl., July 16, 1913.

SEE Fr. Pat. 458,033 of 1912; this J., 1913, 1031.

Process and apparatus for recovering the ether and alcohol vapour contained in the air of factories. Eng. Pat. 101,723. See I.

Apparatus for recovering ether and alcohol vapours contained in the air of factories. Eng. Pat. 101,875. See I.

Manufacturing side-chain chlorine derivatives of toluol [benzyl and benzal chlorides and benzo-trichloride]. U.S. Pat. 1,216,739. See III.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENTS.

Photographic films [for X-rays]. A. Edwards. Warwick. Eng. Pat. 111,913, Dec. 16, 1916. (Appl. No. 18,101 of 1916.)

AN X-ray film of increased speed and uniformity is obtained by coating roll celluloid on both sides with a suitable emulsion.—B. V. S.

Photographs; Method of producing multicoloured —. A. R. Lawshe, Trenton, N.J. U.S. Pat. 1,248,139, Nov. 27, 1917. Date of appl., Feb. 5, 1916.

COLOUR-SELECTION negatives are obtained by exposing together two plates or films, placed face to face, through a suitable light-filter. From these, two coloured positives, red and blue, are obtained and the third colour is introduced by dyeing the film of the blue positive yellow and then removing the dye from the parts of this picture corresponding with the blue parts of the original. The positives are then superposed in register on a reflecting base.—B. V. S.

Colour photographs or films; Method of producing —. F. E. Ives, Philadelphia, Pa. U.S. Pat. 1,248,864, Dec. 4, 1917. Date of appl., Feb. 1, 1916.

COLOURED positives, taken from red and blue-green selection negatives reversed with respect to one another, are fixed permanently together face to face in register. One of the celluloid backings is then dissolved away, the other being first coated with a gelatin or other protective covering.—B.V.S.

XXII.—EXPLOSIVES; MATCHES.

PATENTS.

Nitrocellulose; Utilising the wash-water of the manufacture of —. C. E. B. Seyffert. Troisdorf, Germany. U.S. Pat. 1,218,933, Dec. 4, 1917. Date of appl., July 22, 1915.

THE same water is used for washing successive charges of nitrocellulose containing adhering nitric and sulphuric acids which are progressively stronger in acid. The acids are recovered from the concentrated wash-water.—L. A. C.

Process and apparatus for recovering the ether and alcohol vapour contained in the air of factories. Eng. Pat. 101,723. See I.

Apparatus for recovering ether and alcohol vapours contained in the air of factories. Eng. Pat. 101,875. See I.

XXIII.—ANALYSIS.

Textile fibres; Use of — in microscopic qualitative chemical analysis. E. M. Chamot and H. I. Cole. J. Ind. Eng. Chem., 1918, 10, 48—51. (See this J., 1918, 21A.)

III. *Detection of boron by means of turmeric viscose-silk fibres.* To dye the fibres, a solution of turmeric is prepared by boiling about 20 grms. of ground turmeric root with 50 c.c. of alcohol and adding

to the filtered solution an equal volume of water and $\frac{1}{2}$ —1 c.c. of 10% sodium hydroxide solution. The fibres are immersed in this solution, which is then evaporated to a syrupy consistency in a water-bath. The fibres are removed and immediately dipped in 95% alcohol, pressed between filter paper, dipped in dilute sulphuric acid, washed with water, and dried. Of all fibres tested, viscose-silk gives by far the best colour reaction. To apply the test, a drop of solution of the material to be tested is placed upon an object slide and acidulated with dilute hydrochloric acid. In this drop a turmeric fibre is placed, and the liquid evaporated carefully to complete dryness. The fibre is examined under the microscope. A rose or violet-rose colour indicates boron. To confirm, a drop of a 1% solution of sodium hydroxide is placed upon the fibre. The rose colour immediately turns to Prussian blue, changing to violet. Care must be taken that boron is not present in the object glass and that strong bleaching agents such as hydrogen peroxide or hypochlorites are destroyed. Boric acid can be distinguished from borates in the absence of inorganic salts capable of decomposing a borate by omitting the addition of the mineral acid. Boric acid gives the characteristic colour, but borates fail to do so. A drop of a solution containing 0.000,025 mgrm. of boron gives a positive test by this method.

IV. *Detection of the heavy metals by means of zinc sulphide wool fibres.* Wool, defatted by treatment with a mixture of alcohol and ether, is soaked overnight in a 1% solution of sodium hydroxide. It is then washed and dipped five or six times alternately in solutions of 10% zinc acetate and 10% sodium sulphide, pressing but not washing between the dippings. The wool is then washed and dried between filter papers. A drop of the solution to be tested is placed on the object slide, a drop of dilute hydrochloric acid added, a treated wool fibre introduced, and examined under the microscope. The solution is then evaporated to dryness, a drop of dilute ammonia added, and the fibre examined again, a new fibre also being placed in the drop. The colour of the fibre indicates the following metals: Straw-yellow—tin; lemon-yellow—arsenic, cadmium; orange—antimony; reddish-brown—bismuth; brown or yellow-brown—platinum, copper, mercury (ic), antimony (sometimes cobalt, iron, manganese, nickel); black (brown in very dilute solutions)—silver, lead, gold, mercury (ous). Colourless in acid solution, in alkaline solution the fibre may be brown or yellow-brown if cobalt, iron, manganese, or nickel is present. The colour in all cases depends to a certain extent upon the quantity of metal present.—L. A. C.

Calcium; Rapid method of determining — as calcium sulphate. L. G. Willis and W. H. MacIntire. J. Ind. Eng. Chem., 1917, 9, 1111—1116.

IN the methods in which calcium is determined as sulphate, sulphuric acid is usually employed for the conversion, but, owing to high temperature, loss occurs through dissociation of sulphate, whilst the organic matter contained even in "pure" sulphuric acid causes reduction of sulphate to sulphide. These sources of error may be obviated by using recrystallised ammonium sulphate to convert the calcium salt into sulphate, as first suggested by Schrötter (Fresenius, Quant. Chem. Anal., 1 (1906), 272). The calcium is first precipitated as oxalate, the precipitate ignited, and the residue of calcium carbonate incorporated with a dried, finely powdered mixture of equal parts of ammonium sulphate and ammonium chloride in sufficient quantity to give an excess of about 0.3 gm. of sulphate for each 0.2 gm. of the calcium salt. The mixture is then heated

over a small flame in a crucible inserted in a circular opening in a horizontal asbestos board, until the excess of ammonium salts is expelled. Duplicate determinations should agree within a small fraction of a mgrm.—C. A. M.

Calcium; Volumetric determination of—. J. Grossfeld. *Chem.-Zeit.*, 1917, **41**, 842. (See also *J. Chem. Soc.*, March, 1918.)

THE method depends mainly on the fact that non-crystalline, finely-divided calcium oxalate (such as is obtained from a slightly acid solution in the cold) may be separated by filtration through a "kieselguhr filter-paper" (see this *J.*, 1916, 1105). The slightly acid solution containing about 0.2 gm. of calcium oxide is treated with 10 c.c. of phosphoric acid solution (250 grms. of concentrated phosphoric acid per litre). 15 c.c. of 4% ammonium oxalate solution is added, and the excess of acid is partially neutralised by the addition of 10 c.c. of 10% sodium hydroxide solution; the mixture should now be acid towards litmus paper but not to Congo-red paper. After dilution to 100 c.c. the mixture is filtered through a "kieselguhr filter-paper," and an aliquot portion of the filtrate is acidified with sulphuric acid and titrated with N/10 permanganate solution. The difference between the quantity of permanganate used for this titration and that required for the titration of 10 c.c. of the ammonium oxalate solution, gives the amount of oxalate combined with the calcium and the quantity of the latter is found by a simple calculation.—W. P. S.

Rubidium and cesium; Approximate quantitative method for the determination of— in plant ash. W. O. Robinson. *J. Ind. Eng. Chem.*, 1917, **10**, 50—51.

At least 20 grms. of the dry plant is incinerated below 525° C. The ash is dissolved in hydrochloric acid, the excess evaporated off, and an excess of freshly slaked lime added. The liquid is boiled for a few minutes and filtered. Calcium in the filtrate is precipitated with ammonia and ammonium carbonate, and filtered off, and for precaution a second precipitation is made. The combined filtrates are evaporated to dryness in a muffle just below redness. The residue is treated with hot water, a few drops of hydrochloric acid added, and then about 0.05 gm. of platine chloride. The solution is stirred well and evaporated to pastiness. The unchanged chlorides of sodium and potassium are rapidly dissolved in the minimum amount of hot water, the chloroplatinates washed with 80% alcohol on to a filter consisting of an asbestos pad on perforated platinum foil and reduced by gently heating in a current of hydrogen. The chlorides formed are washed through the filter with hot water, and the filtrate evaporated to pastiness in a small platinum dish. The mass is treated with four drops of strong hydrochloric acid and filtered into a vial of 2—3 c.c. capacity, a number of these being made to hold the same volume. The rare alkali chlorides are treated with two more portions of acid of four drops each, each portion being blown through the filter and the solution then made up to volume. Standards are made up by treating known amounts of cesium and rubidium chlorides and excess of potassium chloride with strong hydrochloric acid as above. These solutions are then examined spectroscopically by evaporating large drops on a coil of platinum wire and holding the residue in a Bunsen flame. Cesium is identified by the doublets 4215.6 and 4201.9 and rubidium by the double lines 4593.3 and 4555.4. The unknown solution is matched with the standards according to the brilliancy of the lines. An accuracy of 5—10% is easily obtainable.—L. A. C.

Iron; Colorimetric determination of—. E. R. Dovey. *Analyst*, 1918, **43**, 31—32.

THE following method obviates errors of comparison caused by differences in the concentration of thiocyanate or in the general composition of the two liquids:—A measured volume of the liquid under examination is treated with the thiocyanate solution, and divided in the proportion of one-third and two-thirds between two Nessler cylinders. The standard iron solution is then added to the smaller portion until its colour matches that of the larger.—C. A. M.

PATENT.

Hardness of metals and other substances; Testing or determining the—. G. Boyelle-Morin, Paris. Eng. Pat. 108,460, Apr. 24, 1917. (Appl. No. 5781 of 1917.) Under Int. Conv., Apr. 25, 1916.

AN apparatus for testing the hardness of metals and other substances by comparison of the indentations produced in the substance and in a body of standard hardness, by the pressure of a hardened steel ball or the like, comprises a cylindrical case having a suitable detachable socket at the lower end for the hardened ball, and a hammer rod within the casing and projecting from the upper end. An aperture is provided for the insertion of a small block of the standard substance between the ball and the hammer rod, and a blow of any desired force is applied to the top of the hammer rod when the implement is held with the ball resting on the body to be tested. An impression is thus produced both on the metal to be tested and on the standard block. To

facilitate computation of the hardness, a slide rule is provided in which two fixed scales are graduated in hardnesses and resistance respectively, and the slide between the scales is graduated in diameters of impressions obtained in a body of standard hardness.—W. F. F.

Calorimeter; Adiabatic —. S. W. Parr, Urbana, Ill. U.S. Pat. 1,247,998, Nov. 27, 1917. Date of appl., Aug. 4, 1916.

AN inner vessel containing the calorimeter bomb immersed in a liquid is completely surrounded by an outer chamber also containing liquid. The outer vessel is provided with suitable stirring and heating appliances to maintain it at a temperature approximately the same as the external temperature of the inner vessel.—B. V. S.

Patent List

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Anderson. Installation for extraction of mineral, animal, and vegetable substances. 1369. Jan. 24.

Barclay. Means for filtering gases. 1495. Jan. 25.

Borstein and Ratner. Drying-chambers. 1563. Jan. 26.

Davidson, and W. C. Holmes and Co. Apparatus for bringing liquids and gases, vapours, fumes, etc., into intimate contact. 1025. Jan. 18.

Donald. Kilns. 1595. Jan. 28.

Donald. Treatment of waste gases from furnaces, kilns, etc., and recovery and utilisation of products. 1596. Jan. 28.

Garrow. Chemical condenser of the Hart type. 1202. Jan. 22.

Johnson. Pumps for corrosive fluids. 1338. Jan. 23.

Kestner Evaporator and Engineering Co., and Reavell. Apparatus for concentrating, distilling, and/or elevating liquids. 1822. Jan. 31.

Lloyd and Wild. Recovery of solvents and volatile liquids. 1500. Jan. 26.

Lynde. Mechanism for vibrating and consolidating powders or plastic material, etc. 1106. Jan. 19.

McClellan. Separating oil from volatile refrigerating-fluid. 1392. Jan. 24.

Morison. Means for maintaining vacuum in condensing plant. 1020. Jan. 18.

Morris. Apparatus for extracting aqueous, etc., vapours from thick or viscid liquids by means of a vacuum. 1718. Jan. 30.

Prisleau. Apparatus for drying moisture-laden substances before distillation. 801. Jan. 14.

Rasch. Centrifugal machines. 875. Jan. 15.

Rothwell. Extracting vapours from stills, boiling and vacuum pans, etc. 1084. Jan. 19.

Smallwood. Furnaces. 1925. Feb. 2.

Soc. l'Air Liquide. Effecting exothermic chemical synthesis under pressure and at a high temperature. 1007. Jan. 17. (Fr., Mar. 31, 1917.)

Soc. l'Air Liquide. Process of effecting exothermic chemical syntheses. 1072. Jan. 18. (Fr., Aug. 7, 1917.)

Soc. d'Exploit. de Procédés Evaporatoires Système Prache et Bouillon. Evaporating and crystallising apparatus for obtaining large crystals, etc. 1171. Jan. 21. (Fr., Jan. 23, 1917.)

Stansfield. Treating smoke, furnace gases, exhaust gases, etc. 1523. Jan. 26.

I.—GENERAL; PLANT; MACHINERY.

Fusion apparatus; Notes on —. F. Pope. Met. and Chem. Eng., 1917, 17, 704—709.

THE common type of fusion apparatus consists of a cast iron pot with agitator of the horse-shoe, gate, or other shape, but rarely of the cone or propeller type. The agitator and shaft should be cast in one piece, as trouble arises if bolts are used in positions exposed to the melt. Agitators for autoclaves should be strongly made, but the shaft should be as small as possible as it has to carry an unbalanced pressure, tending to push it out of the autoclave. In vertical steel autoclaves working at moderate pressure, the use of sloping shaft agitators has advantages. Bottom discharge can be most easily attained when the pot is gas-fired. In such cases ordinary valves and cocks are impracticable. A plug valve with seat and plug of a suitable metal in a horizontal run-off tube at the bottom of the pot can be used. An alternative method is to have the run-off pipe water-cooled, whereby it is closed by a plug of solidified charge, which melts when the water is drawn off and allows the pot to be discharged. The shaft should be lubricated with hard grease, not with oil. The design of safety valves and pressure gauges requires care to avoid their being plugged and rendered inoperative by the melt. Cast steel autoclaves should be cast bottom down with heavy sink heads to be machined off. Forged steel is better than cast steel for large autoclaves. When an enamelled lining is used, the space between it and the outer shell should be filled by running in molten lead or other suitable metal.—H. J. H.

PATENTS.

Gases; Method and apparatus for separating — and the formation of products thereby. A. Mond, London. From L. Bradley, East Orange, N.J., and W. A. Schmidt, Los Angeles, Cal., U.S.A. Eng. Pat. 112,153, Dec. 21, 1916. (Appl. No. 18,303 of 1916.)

SEE U.S. Pat. 1,221,505 of 1917; this J., 1917, 538. The process may be applied to the removal of chlorine from gases by injection of finely-divided calcium hydroxide; the removal of sulphur dioxide, ammonia, or the like from gases by injection of finely-divided charcoal; the separation of sulphur dioxide from air by injecting a finely-divided catalyst, such as iron oxide, chromium oxide, or the like, to convert it into sulphur trioxide; the drying of air for blast-furnaces by injecting a dehydrating agent, such as pulverised calcium chloride; and in the synthesis of ammonia from nitrogen and hydrogen by injecting an absorbing agent for the ammonia, e.g., phosphoric acid or boric acid, into the gaseous mixture.

Filters; Cloth —. W. Boby, London. Eng. Pat. 112,159, Dec. 22, 1916. (Appl. No. 18,394 of 1916.)

A PERFORATED tube is covered with a casing of filter cloth woven from fine wire or hair and is enclosed in an outer tubular casing. The liquid to be filtered is forced into the casing and the clear liquid passes through the cloth into the interior of the perforated tube to the exit. The filter is cleaned by reversing the flow. (Reference is directed in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pat. 9206 of 1887, 16,996 of 1891, 18,716 of 1908, and 12,681 of 1910.)—W. H. C.

Aerating liquids; Machines for —. C. W. Wallace Bruce and Co., Ltd., and E. S. Jones, Newcastle-upon-Tyne. Eng. Pat. 112,165, Dec. 27, 1916. (Appl. No. 18,517 of 1916.)

THE supply of un-aerated liquid to the mixing

chamber is controlled by a float in the reservoir of aerated liquid, so that when the level of liquid in the reservoir reaches a predetermined height the supply of un-aerated liquid is cut off.—W. H. C.

Siphons for corrosive and other liquids. P. J. Channon, Dornoch, Dumfries, Eng. Pat. 112,188, Feb. 13, 1917. (Appl. No. 2160 of 1917.)

THE leg, 2, of the siphon is inserted into the reservoir of liquid, whereby the liquid raises the valve, 3, and partly fills the space between the tubes, 1 and 2. By blowing through the mouth-piece, 6, with the tap open, the liquid is forced up the tube, 1, and starts the siphon, the valve, 3, closing by the pressure. The tap, 6, is then closed and the siphon continues to act.

—W. H. C.

Pulps; Process of replacing solvents in —. G. Moore, Joplin, Mo. U.S. Pat. 1,248,371, Nov. 27, 1917. Date of appl., Mar. 3, 1915.

IN a process of replacing the solvent in pulps, the solids are allowed to settle from the slimes and are then moved in the form of a settled mass, in one direction in the replacing liquid, the latter moving in the opposite direction, but having its motion retarded at the surface so as to form a practically quiescent area into which the lighter solids rising through the advancing liquid are directed. At intervals the advancing liquid is divided into a number of horizontal layers and the solids which separate in the several layers are returned to the mass of settled solids.—J. H. P.

Centrifugal machine. E. R. Curtis, Guildford. Eng. Pat. 112,339, Feb. 12, 1917. (Appl. No. 2107 of 1917.)

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal storage; Modern methods of —. G. F. Zimmer. Engineering, 1918, 105, 30—32, 57—60.

ESTABLISHMENTS depending upon rail service

require to store at least 33% of their annual coal consumption; those depending on water carriage should store 66%, and a stock equal to 6 or 8 weeks' consumption should be kept even by works situated near collieries. The theory that iron pyrites and marcasite are factors in spontaneous heating of coal is not borne out by experiments though it is possible that they may indirectly help through the production of ferrous oxysulphate. Bruigum (Het Gas; through Gas World, June 24, 1916) states that humin and humic acid are the dangerous constituents. Humin, which is the residue left when the coal has been extracted with benzene or the like to remove bitumen, and then with caustic soda solution, to remove humic acid, consists principally of cellulose, and undergoes gradual combustion during weathering. Humic acid will take up much free bromine and also ozone, the latter forming ozonides, which are decomposed in the presence of moisture with formation of carbon dioxide and liberation of heat. Coal absorbs a good deal of oxygen but holds it simply as an absorbed gas, and chemical combination is very slow at ordinary temperatures, but as the heat increases so does the absorption of oxygen, and progressively rising temperatures result. For an effective start, however, ozone must be present, and this is always formed when water evaporates; consequently a damp heap of coal commences weathering, and if circumstances are favourable the temperature begins to rise, and the hitherto inactive oxygen helps in the chemical deterioration. Hence warm weather after rain, and damp sea air laden with ozone are dangerous, especially in a ship's bunkers. Compression and dumping from a height are also causes of rise of temperature and hence sources of danger. The spaces between "large" and "nut" coal provide channels for the air and so facilitate oxidation. During the development of heat, a vapour escapes from the stack and certain acetylenic gases of distinctive odour are evolved, perceptible at a considerable distance. As coal is a poor conductor of heat and has a low specific heat, its temperature may rise rapidly in parts where no cooling air currents can penetrate. When a fire is once established in a coal pile, it is almost impossible to extinguish it with water or steam, the only plan being to dig it out, though in a hoppers bunker it may be quenched by flooding. Chemical extinguishers containing ammonium carbonate are better than water; in some cases gas-works ammonia liquor is effectual. Screening of coal to eliminate smalls and dust before storage is very advantageous. Air penetration is beneficial in a stack, if abundant, but detrimental once heating has taken place. Coal recently mined or freshly broken heats more readily than older coal and it may be advisable to re-handle such coal after two months' stacking. According to Parr (see this J., 1911, 408) any method of storage to be successful must either check or prevent the absorption of oxygen to such an extent that the generation of heat shall not proceed faster than the dissipation and loss of heat due to absorption or radiation. The actual height of storage with safety depends on the character of the coal. The installation of steam pipes is compulsory in American vessels carrying coal, and the distribution of cylinders of compressed carbon dioxide with fusible plugs throughout a cargo has been suggested. The height of the pile is not such an important factor in silos with bottom withdrawal as in stack heaps on the ground. Where site values are high storage in heaps as high as possible is important, though 15 to 20 ft. is a maximum for safety. The kind of coal and method of deposition, however, must be considered. The practice in some naval yards is to stack 14 to 16 ft. high, but in some cases a 34 ft. stack has been found quite safe. At the English gas works in Berlin 60,000 tons of English

coal has been regularly stacked in piles of 50 ft., whilst German coal stored in piles of 16 to 26 ft. has heated, and in some cases caught fire. In any case, all coal stored in the open depreciates in calorific value, the more so with soft and friable qualities.

White (this J., 1917, 24) found that the chemical change produced in Pittsburgh and Fairmont gas coal which had been kept in the open for five years was too small to be recognised by analysis. Storage in the open for 3½ years has been found to have practically no effect on the gas-making properties of the coal, but has a deleterious influence on the quality of the coke (see this J., 1914, 1141). "Pocahontas" coal stored four years under cover showed a loss of calorific value to the extent of only 0.7%. Tests made by the Bureau of Mines on behalf of the U.S. Navy proved that the deterioration of a properly-stacked coal is quite insignificant (see this J., 1912, 112). Porter, in a report to the Department of Mines in Canada, states that the initial temperature of coal at the time of storage is important, also the loss of coal from fire in the second year of storage is about half that in the first year, due to protection offered by the older surface. The Bureau of Mines, at the instance of the U.S. Navy, found that coal stored for two years in fresh water lost nothing, in salt water 0.395%; indoors exposed to air, 0.383%; outdoors uncovered, 0.997%.

Methods usually employed in storing are:—(1) An ordinary pile, open or covered, sides generally open; (2) in pockets or silos, open at the base and capable of drainage; (3) under water. Method (2) is more rational than (1) and prevents the accumulation of small coal, and the coal at the deepest part of the pile is kept sufficiently in motion for the bulk to be slightly broken every time coal is withdrawn, thus minimising spontaneous heating and making admissible a higher pile; a large outlet is an advantage because of ventilating and cooling and also preventing bridging of large pieces likely to cause blockage. Method (3) is probably the most expensive, but in the end the most economical; fresh water is quite as effectual as sea water. At Chicago 12 pits 80 ft. by 25 ft. by 16 ft. deep were employed, holding together 14,000 tons of coal under water without apparent deterioration; the largest plant for this purpose is at Brunot's Island, Pittsburgh, consisting of a pit of ferro-concrete 800 ft. long, 150 ft. wide, and 25 ft. 6 in. deep, with sides sloping at 45°, which will hold a maximum of 100,000 tons of coal. Coal recovered from the battleship "Maine" which had been submerged 14 years, showed a heating value of 8588 calories and had deteriorated 160 calories, or 1.9%.—T. H. B.

Hydrogen: Absorption of — by sodium oleate. Reagents for use in gas analysis. VI. IR. P. Anderson and M. H. Katz. J. Ind. Eng. Chem., 1918, 10, 23—24.

BOSSHARD and Fischli (this J., 1915, 1079) suggest the use of a solution of sodium oleate containing nickel in suspension for the absorption of hydrogen in gas analysis. The authors prepared metallic nickel by the reduction of nickelous oxide by hydrogen at 340° C., keeping the metal out of contact with air after production, and they employed a 10% solution of sodium oleate for most of their experiments, stronger solutions solidifying too rapidly to be of use. They found that absorption of hydrogen by the above reagent was very incomplete under all the conditions they employed, and they gave up the attempt to find conditions of complete absorption, finding that the method had several objections which render it of little value.—L. A. C.

Benzene vapour; Determination of —. *Reagents for use in gas analysis*. I. H. R. P. Anderson. *J. Ind. Eng. Chem.*, 1918, 10, 25–26.

THE author summarises various methods for the determination of benzene vapour in gas, and suggests a method in which a measured quantity of gas containing benzene vapour is placed in contact with benzene in a special apparatus, and the increase in volume read. By determining what the increase would have been had there been no benzene vapour present, the amount actually present can be determined. A standard apparatus has not yet been produced.—L. A. C.

[Oil] refining process; The Trumble —. N. W. Thompson. *Amer. Soc. Mech. Eng.*, Dec., 1917. *Engineering*, 1918, 105, 63–65.

THE crude oil enters the plant through a 6 in. main, passing first of all through six coolers. These are of the horizontal tubular type, 30 in. in diameter, with sixty-two 2 in. by 18 ft. tubes. The oil, entering at the bottom, flows through the tubes, making four passes, and leaves at the top, passing on to four heat-exchangers, each 48 in. in diameter and containing 178 tubes 2 in. by 18 ft. These heat-exchangers are connected in series, and the oil, on leaving the last, passes on to the heater pipes. Here the flow of oil is split in two, each half passing in series through 72 lengths (18½ ft.) of 4-in. pipe, flowing backwards and forwards, but upwards at all times, and then into the top of the evaporator. Both the heater pipes and the evaporator are heated by flue-gases. The evaporator consists of a closed vertical cylindrical shell. Inside is a central vertical pipe having umbrella-shaped devices ("spreader hoods") attached thereto at intervals. The oil, fed to the apex of these hoods, flows down over their sides in a thin film, striking against the interior wall of the evaporator, which is separated from the lower edges of the hoods, and flowing down the wall in a thin continuous film. The central vertical pipe is provided with perforations under each of the hoods, through which the vapour passes off. Lateral connections through the walls of the chamber convey the vapour through an oil separator similar to a steam separator, the oil passing back to the bottom of the evaporator. The vapour then passes through six large dephlegmators in series, a system of water circulation serving as a cooling medium. From some of these, the condensed liquid is a finished product; from others it is an intermediate product. The residuum in the bottom of the evaporator is drawn off at a constant head and is used as a heating medium in the separators and heat-exchangers, through which it flows counter-current to the crude oil. On leaving the last of the series, it passes on to storage tanks. At the bottom of the evaporators, separators, and dephlegmators are superheated steam coils to agitate the liquid and expel the lower boiling-point fractions. The separators are re-run stills for distillates from the bottoms of the dephlegmators, or from any other source, which need fractionating. The distillate flows through a series of six compartments over pipes through which there is a regulated flow of a suitable heating medium, *e.g.*, evaporator residuum. The vapours generated pass off through openings at the top of the compartments and are condensed. The following advantages are claimed for this process: The oil while being vaporised is never exposed to any action tending to "crack" the constituents. This is particularly advantageous in the production of asphaltum for road work. In passing through the apparatus the oil is not subjected to direct heat for any period of time, nor in the quiescent state, thus preventing burning and cracking. By regulating the fires and flow of oil, a uniform product can be obtained in any

quantity. The system is economical, only 1.1% of the crude oil being used as fuel and the loss of non-condensable gases being only 0.75%. The amount of labour required is small.—L. A. C.

PATENTS.

[Coal:] Apparatus for mechanically separating materials [—from rock]. A. Lotozky, Charkoff, Russia. *Eng. Pat.* 112,227, May 4, 1917. (*Appl. No.* 6372 of 1917.)

IN an apparatus for separating coal from rock mechanically, a number of polished discs, spaced apart, are mounted on a rotating shaft inclined to the vertical at an angle which is between the angles of friction of the coal on the discs at rest and in motion. The mixed coal and rock are fed on to the discs from tangential shoots inclined downward, parallel to the plane of the discs, and on that side of the discs which is moving in the opposite direction. The mixture is fed into the shoots from a box having distributing partitions, which is suspended by hangers and vibrated by a rotating ratchet below, acting through a spring which may be adjusted to vary the vibration. The coal is not subject to centrifugal force due to the rotation of the discs, but moves downward directly to the outlet at the lower edge of the discs. The rock, owing to its higher coefficient of friction, is carried round by the discs to an outlet opposite the coal outlet. To prevent the rock from being carried past its outlet, a wooden tongue is provided sliding freely between two parallel metal strips, resting freely on the disc, and projecting inwards from the further edge of the outlet. The inclination of the whole apparatus may be adjusted, by means of a worm gearing, about a horizontal axis coinciding with that of the driving shaft which operates the discs through bevel gearing.—W. F. F.

Fuel; Manufacture of composition —. C. T. Hopkins, Walthamstow, Essex. *Eng. Pat.* 112,341. (*Appl. Nos.* 2233, Feb. 14, and 10,517, July 21, 1917.) *Addition to Eng. Pat.* 14,771, Oct. 19, 1915 (this J., 1916, 826).

A MIXTURE of small coal and soot, with or without other ingredients, is mixed with water to a semi-liquid condition, allowed to stand for not more than 30 mins., and the floating material skimmed off. The liquid carrying the lighter suspended solids is decanted and allowed to settle for 24 hours, and the clear liquid then drawn off. This liquid may be used as a fertiliser, or as a pickling bath for iron and other metals preparatory to electrolytic treatment. The fine sediment dries into solid blocks without pressure and may be used as a fuel, or, with the addition of water, may be used as a binder for coal, coke, cinders, and the like. The coarse residue from the original mixture may be moulded alone or mixed with the binding material described above, and used as a fuel.

—W. F. F.

Furnaces for the combustion of pulverulent fuel. J. E. Muhlfeld, Scarsdale, N.Y., and V. Z. Caracristi, Bronxville, N.Y., U.S.A. *Eng. Pat.* 112,155, Sept. 13, 1915. (*Appl. No.* 18,306 of 1914.)

IN an apparatus for burning pulverulent fuel, the mixed fuel and air are injected tangentially at one end of a horizontal cylindrical preliminary combustion chamber, the nozzle being inclined to the axis of the chamber so as to produce a helical stream. The angle of the fuel jet may be varied so as to vary the time during which the fuel is in the chamber, to suit different varieties of fuel. A trough may be provided in the bottom of the chamber to collect any solid combustion products, which are then blown out by a jet of compressed air. The burning fuel passes into a main

combustion chamber and thence to a flue. In a modification, the fuel is injected downwards along the inclined bottom of the combustion chamber and then passes upwards through the chamber in a tortuous path formed by two baffles projecting alternately from opposite sides of the chamber and extending about halfway across. A zone of retarded flow is thus produced between two zones of accelerated flow, and an additional supply of air is admitted into this middle zone. This may be done by openings in the walls, or by making the projecting baffle hollow and communicating with the atmosphere. The combustion products then pass through any desired heating apparatus, such as boiler tubes, to the flue. The apparatus is especially suitable for use with the apparatus for feeding pulverulent fuel described in Eng. Pat. 13,067 of 1915 (this J., 1917, 200) and is described in detail as applied to a locomotive furnace.

—W. F. F.

Aromatic bodies; Apparatus for the manufacture of — from petroleum oils. F. W. Mann, Berkeley, and M. L. Chappell, El Segundo, Cal., Assignors to Standard Oil Co., Richmond, Cal. U.S. Pat. 1,249,144, Dec. 11, 1917. Date of appl., May 3, 1917.

THE oil to be treated, mixed with the necessary volume of air for the desired reaction, is supplied to a converter containing a contact material. A supply of liquid fuel is burnt within the converter under such conditions as to produce its complete combustion and maintain the reaction temperature, and the reaction products are discharged to the suction side of a compressor which maintains a pressure below atmospheric in the converter. The compressor delivers the vapour to a condensing system. A controllable outlet is provided in the converter on the side of the contact material opposite to the air supply inlet.—W. F. F.

Petroleum oils; Double evaporator and process of treating —. M. J. Trumble, Los Angeles, Cal., Assignor to Simplex Refining Co., U.S. Pat. 1,250,052, Dec. 11, 1917. Date of appl., Dec. 5, 1914.

THE oil is heated to a moderate temperature in an evaporator, and the vapour drawn off. The residue is transferred to a second evaporator where it is heated to a higher temperature, and the residue and vapour drawn off. The latent heat of the latter vapour is recovered by passing it through a heating compartment in the first evaporator, for the preliminary evaporation of the oil.—W. F. F.

Coal; Process of and apparatus for treating —. C. H. Smith, Short Hills, N.J., U.S.A. Eng. Pat. 106,084, Dec. 21, 1916. (Appl. No. 18,295 of 1916.) Under Int. Conv., May 5, 1916.

SEE U.S. Pat. 1,224,421 of 1917; this J., 1917, 636.

Coal-gas; Manufacture of —. A. Waddell, Dunfermline, Scotland. U.S. Pat. 1,249,864, Dec. 11, 1917. Date of appl., Feb. 29, 1916.

SEE Eng. Pats. 5611 and 14,142 of 1915; this J., 1916, 625.

Hydrocarbons; Process of transforming — into other hydrocarbons relatively poorer in hydrogen. Bostaph Engineering Co., Assignees of A. S. Ramage, Detroit, Mich., U.S.A. Eng. Pat. 106,080, Sept. 21, 1916. (Appl. No. 13,428 of 1916.) Under Int. Conv., Apr. 27, 1916.

Electric [incandescence] lamp or other vacuum tube having a copper leading wire. T. Yanai, G. Ohtani, and S. Yago, Tokyo, Japan. Eng. Pat. 103,648, Jan. 2, 1917. (Appl. No. 90 of 1917.) Under Int. Conv., Jan. 26, 1916.

COPPER wire, to be used as the leading-in wire of an electric lamp or other vacuum tube, is first hammered or rolled to a suitable form to give a great surface area, and then coated with a layer of oxide on its surface by heating or by immersion in an acid or alkaline oxidising bath. The wire is thrust through a heated glass rod, and the whole afterwards heated to a high temperature to bring about combination between the oxide and the glass.—B. N.

Process for the purification of crude alcohols. Eng. Pat. 112,166. See XX.

III.—TAR AND TAR PRODUCTS.

Tars; Effects of certain solvents on the determination of "free carbon" in —. G. S. Monroe and H. J. Broderson. J. Ind. Eng. Chem., 1917, 9, 1100—1101.

TARS were left in contact with various solvents for different periods of time, and the amounts of "free carbon" determined by Weiss's method (this J., 1914, 474). The results showed a gradual increase with the time when benzene, bromobenzene, and chloroform were used. In other experiments the tar was digested with the solvent on the water-bath for definite periods, and then extracted with the same solvent, and the insoluble residue dried and weighed as free carbon. In the case of water-gas tar and gas-works tar the amounts of free carbon gradually approached a maximum, and then decreased, when benzene was used as solvent. In like manner, there was a gradual increase in the free carbon on continued digestion of gas-works tar with toluene, but in the case of coke-oven tar no maximum point was reached. In the digestions with chloroform no maximum point was reached in the case of any of the tars, although there was a gradual rise in the percentage of free carbon. Fluctuations in the boiling points of the solutions during the digestion indicated the probability of the occurrence of chemical reactions during the digestion of tars with chloroform, but these would not account completely for the gradual increase in the free carbon residues on continued digestion. Possibly free carbon present in colloidal form may be precipitated by dilution. Benzene, toluene, and carbon bisulphide do not react chemically with tar, and should therefore be preferred to chloroform for the determination of free carbon.—C.A.M.

Naphthalene; Solidifying point of —. G. V. Heyl. Met. and Chem. Eng., 1917, 17, 681.

A SOLIDIFYING point lying between 79° and 80° C., or a few decimal points above, is not always a true

indication of the purity of refined naphthalene. It is of as little value as proof of the absence of phenoloids, etc., as the "acid test." Naphthalene refined from flue-gas tar always shows a characteristic "acid test," although no traces of phenols or cresols are present. It is important that the refiner should furnish the dye manufacturer with a purer material. The failure of the latter to produce certain dyestuffs successfully is largely due to impurity of the prime materials, particularly in the case of naphthol and amine dyes. Samples of naphthalene of the same solidifying point and of nearly the same "acid test," but refined from different tars, may give entirely different yields on sulphonation or conversion to β -naphthol. All traces of aliphatic hydrocarbons must be removed from naphthalene produced from water gas tar. On subliming naphthalene containing these bodies, a pure white brittle flake is obtained giving a fair "acid test," but with a solidifying point not above 79.3°C .; this material gives very unsatisfactory results on nitration and halogenation.

—L. A. C.

Phenol; Estimation of— in the presence of the three cresols. G. W. Knight, C. T. Lincoln, G. Formanek, and H. L. Follett. J. Ind. Eng. Chem., 1918, 10, 9—18.

For the determination of phenol in commercial products it is necessary to remove completely hydrocarbons, xylenols and higher homologues, and bases. Hydrocarbons are effectively removed by diluting the original sample with two volumes of benzol before extracting with caustic soda. Bases are removed during the separation of the tar acids. For the separation of xylenols and higher homologues a special still-head has been devised. This consists of three 2-in. bulbs joined by two glass tubes $\frac{3}{16}$ in. long and having a $\frac{3}{8}$ in. aperture. The upper bulb is connected with a glass tube open at the top ($\frac{1}{8}$ in. internal diameter and 3 in. long) having a side tube ($\frac{3}{8}$ in. internal diameter) bent downwards at a suitable angle. The lowest bulb has a glass siphon tube ($\frac{1}{8}$ in. internal diameter) joined to the side of the bottom of the bulb, bending at first upwards to about half the height of the bulb and then downwards, passing through and down the centre of another tube, $4\frac{1}{2}$ in. long and $\frac{3}{8}$ in. internal diameter along $3\frac{1}{2}$ in. of the lower part and $\frac{3}{8}$ in. inside diameter along 1 in. of the upper part, where it is joined to the lowest bulb. A Tirrell burner should be used for heating the distillation flask. One hundred grams of the sample is poured into a 500 c.c. separating funnel, and the flask rinsed out with 200 c.c. of benzol; 100 c.c. of 20% caustic soda is then added, the whole shaken thoroughly for two minutes, allowed to settle and the lower layer drawn off into another funnel of 600—700 c.c. capacity. The benzol layer is washed with three or four 100 c.c. portions of 20% caustic soda. The caustic soda extracts are washed with 30 c.c. portions of benzol until hydrocarbons are all removed. The combined benzol extracts are washed twice with 10 c.c. of 20% caustic soda and the washings added to the caustic soda solution. The solution is then just acidified with dilute sulphuric acid, keeping the temperature below 40°C ., and allowed to settle in a separating funnel. The lower layer is drawn off into another funnel, the acid water layer washed with successive portions of benzol, the mixed benzol extracts then being treated with 10 c.c. of saturated salt solution. The tar acids are poured into a 300 c.c. round-bottom Jena glass distilling flask fitted with a Wurtz still-head, the funnel being washed out with the benzol extract. Benzol and water are distilled off to 170°C . into a separating funnel. The still is then cooled and the still-head removed and rinsed out with benzol which is added to the distillate. This is saturated with salt, shaken separated, and the benzol com-

pletely extracted with 5 c.c. portions of 20% caustic soda solution. The extract is acidified and the tar acids which separate added to the distilling flask. The distillation is now continued, using the Knight still-head and a standardised thermometer accurate to $\frac{1}{2}^{\circ}\text{C}$. between 170° and 210°C . Correction must be made for emergent stem, the correction being $0.00016N(T^{\circ}-t^{\circ})$ (N is number of degrees exposed, T° and t° the temperatures of the thermometer bulb and the exposed stem respectively). The distillate is collected in a 10 c.c. burette until the oil passes over clear, and then in a tared 100 c.c. cylinder up to 193°C . The water layer in the burette is saturated with salt and the tar acids added to the distilling flask, the distillation being continued to 206°C ., with a fresh receiver, at a rate of 0.5 to 1.0 c.c. per min. This portion is redistilled in another flask to 201°C ., the distillate being collected in the cylinder used for collecting to 193°C . The cylinder is again weighed and 1.5 grms. of the distillate mixed with 10.5 grms. of *o*-cresol (sp. gr. $25^{\circ}/25^{\circ}$, G_{50} , and solidifying point, T_{50} , above 28°C .). The specific gravity at $45^{\circ}/45^{\circ}\text{C}$. (G_{45}) of the mixture is determined in a 10 c.c. Geissler pycnometer, and the solidifying point (T_{50}), using a standard thermometer. The specific gravity at $45^{\circ}/45^{\circ}\text{C}$. (G_{45}) and solidifying point (T_{50}) of the distillate mixed with phenol (of sp. gr. at $45^{\circ}/45^{\circ}\text{C}$., G_p , and solidifying point, T_p , not below 40°C .), instead of with *o*-cresol are then determined. The percentage of phenol is then calculated from the formula: Per cent. phenol = $100D[(T_{50}-T_o)(0.366+0.702 L_s) + (G_{50}-G_o)(2970-609 L_s)] \div 30w$ where $L_s = [1000(G_p-G_{sp})/(T_p-T_{sp})] - 0.482$ w = wt. of sample used and D = wt. of distillate below 199°C . This method does not give absolutely accurate results with all possible mixtures of the three isomers with phenol, but in all cases ordinarily met with in commercial practice, the probable error would amount to only a few tenths per cent.—L.A.C.

PATENT.

Apparatus for the manufacture of aromatic bodies from petroleum oils. U.S. Pat. 1,249,411. See II A.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Testing of paper, textiles, etc.; A constant temperature and humidity room for —. F. P. Veitch and E. O. Reed. J. Ind. Eng. Chem., 1918, 10, 38—44.

The room is 10 ft. 6 in. by 14 ft. 3 in. by 9 ft. 3 in. high. The walls and ceiling are 8 in. thick and consist of an outer 4-in. layer of ground cork, a thin partition, and two layers of sheet cork $1\frac{1}{2}$ in. thick, the inner layer being cemented on the inside to prevent absorption of moisture. Air is drawn into one corner of the room near the ceiling and passes out through openings in a flue with hand-controlled dampers. Two fans in the room prevent stratification of the air. The temperature of the incoming air is regulated by steam and brine coils and the humidity by a steam valve, the coils and valve being regulated respectively by a thermostat and a hygrostat situated in the room.—L. A. C.

Paper; Method for determining the absorbency of —. E. O. Reed. J. Ind. Eng. Chem., 1918, 10, 44—47.

A 4 in. square of blotting paper is placed over a beaker or tumbler and a 1 c.c. pipette supported vertically above it with the tip $\frac{1}{2}$ in. above the centre. A pipette with a delivery time of ap-

proximately 4 secs. should be used. The pipette is filled with water or preferably with a standard ink and allowed to drain on to the paper, which should be dished slightly. The blot should not extend to the sides of the supporting vessel. The average time in seconds of complete absorption for three experiments is recorded. This gives a relative value for the absorptive power of the paper which is claimed to be more accurate than either the mounting test or the measurement of zones formed by blots of ink. For copying paper, filter paper, and very thin blotting paper, 0.5 c.c. of water should be used.—L. A. C.

Preparation of uniform collodion membranes for dialysis. Farmer. See XXIII.

Silk and silk waste ; Process for ungumming —. Gebr. Schmid, Basle, Switzerland. Eng. Pat. 107,966, June 20, 1917. (Appl. No. 8856 of 1917.) Under Int. Conv., July 10, 1916.

In the process described in Eng. Pat. 100,029 of 1916 (this J., 1916, 733) for the degumming of silk and silk waste, the substitution of a portion of the soap by certain silk wastes known as "gallettadini" or "pelettes" or by silk-worm chrysalides may be increased until as much as nineteen-twentieths of the quantity of soap usually employed has been thus replaced by these natural lather-forming substances. A suitable bath is prepared with 1 kilo. of soap and 10 kilos. of silk-worm chrysalides or gallettadini. The alkalinity of the bath may be increased, if necessary, by the addition of crystallised soda.—J. F. B.

Fibrous materials ; Process for separating impurities from waste —. J. J. Werst, Arnhem, Assignor to Naaml. Vennootschap Neo-Cellulose Maatschappij, Rotterdam, Netherlands. U.S. Pat. 1,249,575, Dec. 11, 1917. Date of appl. May 22, 1916.

VI.—BLEACHING ; DYEING ; PRINTING ; FINISHING.

Bleaching powder ; Effect of light on solutions of —. R. L. Taylor. J. Soc. Dyers and Col., 1917, 33, 246—250.

The conclusions of Lunge and Landolt (J. Soc. Dyers and Col., Nov., 1885), and the character of the reactions has been investigated. Evolution of oxygen as noted by Foerster and Dolch (this J., 1917, 546) in the case of sodium hypochlorite was found to be relatively the greatest in a strong solution of bleaching powder kept in the dark, the solution in which the total oxidising power changed the least. A solution containing a relatively smaller amount of free lime bleaches more rapidly and is more liable to decompose. A solution containing 10 grms. of bleaching powder per litre was unchanged after keeping in the dark for 15 months; the amount of free lime has no influence on the stability of solutions kept in the dark. It is concluded that it is of great importance in keeping bleaching solutions for use to preserve them from the action of light.—F. W. A.

Ferrocyanides and ferricyanides ; Mordanting action of —. A. B. Clark. Communication No. 46 from Research Lab. of Eastman Kodak Co. J. Phys. Chem., 1917, 21, 776—784.

MORDANTING action is a function of the nature of the dye, of the acid and metal united in the mordant, and also probably of the concentration of the ions in the solutions, and possibly an effect of exposure to light, e.g., in the case of silver compounds; as in all dyeing processes, the concen-

tration of hydrogen and hydroxyl ions and of neutral salt has a great influence on the result. The results are also greatly affected by the physical state of the mordant, i.e., colloidal or crystalline, and are much complicated in case the mordant is in gelatin. The experiments described were conducted in a system containing only water, the mordant, the inorganic salt resulting from the action of the soluble metal and acid salts, the dyestuff, and a slight excess of acid salt to ensure uniformity. The dyestuffs selected represented the common groups from the standpoint of chemical classification, together with others representing special characteristics of the organic molecule. The mordanting power was tested by preparing suspensions of the insoluble ferri- or ferrocyanide of such molar concentrations as to show clearly the relative mordanting action; the various dyestuff solutions were added, and the amount of dyestuff in solution after the precipitate had settled out was roughly determined by comparison with standards. A relation exists between mordanting power of a metal and its position in the periodic table; the high-valent metals of high atomic weight form ferro- and ferricyanides of high mordanting power, with certain irregularities probably due to difference in physical state of subdivision. All ferricyanides act better as mordants for basic dyestuffs than for acid dyestuffs in presence of a slight excess of ferricyanide ion. All ferrocyanides act as mordants for basic dyestuffs in presence of an excess of ferrocyanide ion, with the exception of lead ferrocyanide, possibly due to formation of a basic salt, and thorium ferrocyanide, probably due to the heavy multivalent ion which tends to precipitate acid dyestuffs. Ferricyanides are better mordants than ferrocyanides. Mordanting power in presence of a slight excess of cyanogen compound is primarily a function of the molecular weight and valence of the metals. Secondary factors are the physical state of subdivision and molecular weight of the mordant. It is probable that the nature of the adsorption complex varies in most cases with the ionic concentration in solutions.—F. W. A.

PATENTS.

Dyeing and bleaching machine. T. Allsop and W. W. Sibson, Assignors to The Philadelphia Drying Machine Co., Philadelphia, Pa. U.S. Pats. (A) 1,246,835 and (B) 1,246,836, Nov. 20, 1917. Dates of appl., (A) Aug. 7 and (B) Sept. 18, 1916.

(A) IN a dyeing and bleaching machine, a rotary cylinder is mounted axially in a tank on an inlet pipe into which the treating liquor is introduced by a pump, an outlet pipe from the tank leading to the pump, whereby a continuous circulation of liquor is maintained. The liquor is heated whilst passing through the pump by the introduction of steam. (B) A closed steam pipe is contained in the portion of the perforated outlet pipe within the tank.—F. W. A.

Dyeing and analogous purposes ; Machinery for use in —. A. Seeley, Rochdale. U.S. Pat. 1,249,677, Dec. 11, 1917. Date of appl. Mar. 16, 1916.

VII.—ACIDS ; ALKALIS ; SALTS ; NON-METALLIC ELEMENTS.

Hydrochloric acid ; Detection and determination of small quantities of free — in the presence of chlorides and other mineral or organic acids. M. Entat. Ann. Chim. Analyt., 1918, 23, 5—7.

THE electrometric titration method described previously (this J., 1917, 545) for the determination of sulphuric acid may be applied to hydrochloric

acid. The hydrochloric acid solution under examination should contain 2% of nitric acid and the titration made with $N/1$ silver nitrate solution. The curve plotted from readings shows an inflexion at the point where all the free hydrochloric acid has been precipitated.—W. P. S.

Formic acid or formates: Volumetric determination of— in the presence of hydroxides, carbonates, oxalates, and acetates. F. Tsiropinas. J. Ind. Eng. Chem., 1917, 9, 1110—1111.

FIFTY c.c. of the solution containing from 0.5 to 1 gm. of formic acid is introduced into an Erlenmeyer flask, and, if alkaline, is acidified with dilute (1:1) sulphuric acid, and treated with 400 c.c. of chromic acid solution prepared by dissolving 50 grms. of pure sodium bichromate in 500 c.c. of water, adding 80 c.c. of pure sulphuric acid, and boiling for 5 mins. The flask is attached to a reflux condenser the upper end of which is connected with a graduated gas-measuring tube holding about 600 c.c., and having its lower end connected by means of rubber tubing with a levelling bulb. After the measuring tube has been filled with water to the zero mark, the contents of the flask are boiled for about 15 to 20 mins. until the volume of carbon dioxide in the tube is practically constant. The volume is then reduced to standard pressure and temperature, a correction made for the volume of air displaced by the stopper at the beginning of the determination, and the weight of carbon dioxide calculated into the equivalent amount of formic acid. In the presence of carbonates, bicarbonates, oxalates, and acetates, the solution, which should contain between 2.5 and 5 grms. of formic acid, is boiled for a few minutes, made alkaline with sodium hydroxide if bicarbonates are present, and treated with sufficient calcium chloride solution to precipitate the carbonates and oxalates. The filtrate and washings from the precipitate are made up to 250 c.c., and the formic acid determined in 50 c.c. of this solution. Acetates, which remain in solution, are not oxidised by the chromic acid solution. The average result obtained in test determinations of mixtures containing 0.5 gm. of sodium formate was 0.4982 gm.—C. A. M.

Nebraska potash industry. E. E. Thum. Met. and Chem. Eng., 1917, 17, 693—698. (See also this J., 1917, 595.)

A MORE detailed account of the Nebraska potash lakes and their exploitation is given. All the plants are working substantially as stated in the previous note. In one case preliminary evaporation by solar heat is employed. In the drying of the saturated brine, different expedients have been employed. In one plant the brine is run down an oil-fired rotary kiln as used for cement burning, and the salts accumulate in small nodules. In another works the brine is sprayed into the oil flame placed axially in the upper end of the furnace. Very efficient and almost instantaneous drying occurs and the salt is discharged in powder form. In another works the drying is carried to the stage of fritting and the salt is discharged as a hot clinker which is sprayed with saturated brine. This is evaporated by the heat of the clinker, which is disintegrated in the cooling process. Flue losses of potash in all cases are considerable. The Nebraska region is now producing potash salts (25% K_2O) at the rate of 32,000 tons of K_2O per annum, whereas in 1916 the total production of the United States was only 9720 tons. The pre-war consumption was 275,000 tons.—H. J. H.

Potash: Commercial aspect of recovery of— in pig iron manufacture. K. M. Chance. Cleveland Inst. Eng., Jan. 15, 1918. (Chem. Trade J., 1918, 62, 44. (See also this J., 1917, 1006.)

NORMALLY there is from 15 to 30 tons of potash in

the burden charged into iron blast furnaces to produce 1000 tons of pig iron. At this rate 200,000 tons of potash is annually fed into the blast furnaces of this country and of this about 50,000 tons is carried out of the furnaces in the blast-furnace gas. This quantity can be increased by the addition of salt to the charge (see Eng. Pat. 112,338 of 1917; following) and so far as known at present without detriment to the furnace lining. From the dust deposited by the gas it is practicable to produce a potash fertiliser with only 5% of impurities, whereas the German kainit contained only about 20% K_2O . A very pure potash can also be prepared from the aqueous washings of wool, and there are still other sources available in this country. The exploitation of these would speedily enable the demand for home consumption to be met without importation. A company, half the shares in which are held by the Government, has been formed for the home production of potash, and one factory has already been erected at Oldbury. The author regards the commercial prospects of the industry as very favourable.—H. J. H.

Potash: Recovery of— from greensand. H. W. Charlton. J. Ind. Eng. Chem., 1918, 10, 6—8.

FINELY ground greensand is digested in an autoclave with lime and water at a pressure of about 225 lb. for 2—4 hrs., high-pressure steam being admitted to maintain the required temperature and pressure. On completion, the contents are filtered, the filtrate containing potassium hydroxide in a relatively pure state. The residue, on the commercial utilisation of which the success of the method depends, may be successfully employed as a cementing agent in the manufacture of steam-hardened bricks, tiles, etc.; it may also be moulded and dried without admixture with sand to form insulating fireproof blocks. The method may also be employed for the extraction of potash from felspar, this material, however, giving a potash containing soda and alumina, which have to be separated. One ton of greensand is capable of producing about 100 lb. of K_2O , and cement for twenty to thirty thousand bricks.—L. A. C.

Phosphate rock: Electric furnace smelting of— and use of the Cottrell precipitator in collecting the volatilised phosphoric acid. J. N. Carothers. J. Ind. Eng. Chem., 1918, 10, 35—38.

WORK done previously (see this J., 1917, 134) has been continued on a commercial scale. The furnace consisted of a water-cooled crucible lined with firebrick, but silica brick is recommended as likely to prove more satisfactory. The gas mains and cooling tower also had a firebrick lining. The graphite electrodes entered through the top of the furnace and were controlled by hand. A current of 220 volts was used for starting, but one of 110 volts was found satisfactory for operating. The P_2O_5 content of the slag was approximately 2%, but it is possible to reduce it to 1.5 or even 1% with regular operation. The average production was 0.3 lb. of H_3PO_4 per kilowatt-hr., but it should be possible to double this figure. The gases on leaving the furnace passed through a cooling tower so designed that they entered the treater at 250°—300° C. The treater contained a header of common brick and 20 treater tubes of vitrified sewer pipes, 2 in. in diameter and 15 ft. in length, all being enclosed at the top in a common hood. Supports for the conductors rested on insulators within the treater hood. The treater was capable of dealing with 2000 cub. ft. of gas entering at 300° C. with a velocity of 3 ft. per sec. It was found that 70 kilo-volts was sufficient to give complete precipitation of the suspended matter in the gases at the above-stated volume and velocity. As the acid fell from the pipes it was caught in a

receiving basin and removed. The concentration of the acid was controlled by the temperature of the gas in the treater; at less than $100^{\circ}\text{C}.$ the concentration did not exceed 50%; at $250^{\circ}\text{C}.$ — $300^{\circ}\text{C}.$ an acid of 85—93% H_3PO_4 was obtained. Unscreened rock was found to be undesirable, as dust is likely to be carried over; with a dust-free rock, the only impurities likely to be present in the resultant acid are carbon, silica, fluorine, and arsenic.—L. PATENTS.

Acid receptacles; Outlet for —. J. J. Dye and W. A. Lucas, Newark, N.J., Assignors to Butterworth-Judson Corporation. U.S. Pat. 1,249,728, Dec. 11, 1917. Date of appl. June 12, 1917.

AN acid receiver of refractory material is provided on the outside with a box of similar material communicating with the receiver. An outlet pipe communicates with the box, and is provided with a flange at a point outside the box. The box is surrounded by a sheet of acid-proof metal, having a tubular portion which forms a sleeve to the outlet pipe, the end of the sleeve being clamped to the flange on the outlet pipe.—F. Sp.

Sodium hydroxide; Production of —. C. S. Bradley, New York. U.S. Pat. 1,249,314, Dec. 11, 1917. Date of appl. Feb. 26, 1915.

AMMONIUM carbonate is formed by the action of barium carbonate on ammonium chloride, and from it sodium carbonate is produced by the ammonia-soda process, with reproduction of ammonium chloride. The sodium carbonate is causticised first with calcium hydroxide and then with barium hydroxide, the latter being produced from the barium chloride formed in the first reaction by means of a portion of the caustic soda produced in the causticising process.—F. Sp.

Ammonium chloride; Recovery of — from ammoniacal liquor, with extraction of cyanides and other valuable products. H. Baker, Barrow-in-Furness. Eng. Pat. 112,329, Jan. 17, 1917. (Appl. No. 836 of 1917.)

AMMONIACAL liquor is boiled to remove free ammonia, which is recovered as liquid or gaseous ammonia, or as ammonium salts. The liquor is then treated with the oxide or chloride of copper, tin, silver, aluminium, or nickel, either singly or mixed, to remove cyanides as an insoluble precipitate. Excess of the reagents is precipitated by treating the liquor with hydrogen sulphide, or unpurified coal gas, or a mixture of the two. Ammonium chloride of moderate purity is then obtained by concentrating the liquor until it crystallises, or evaporating it to dryness.—F. Sp.

Potassium chloride; Production of — [in manufacture of pig iron]. British Cyanides Co., Ltd., K. M. Chance, and E. C. Rossiter, London, and North Lincolnshire Iron Co., Manchester. Eng. Pat. 112,338, Feb. 8, 1917. (Appl. No. 1960 of 1917.)

SODIUM chloride or an alkaline-earth chloride is

added to the ordinary blast-furnace charge in the manufacture of pig iron. The flue gases contain nearly all the potassium of the charge in the form of potassium chloride, which is extracted from the flue gases by a wet or dry cleaning process.—F. Sp.

Cement-kiln dust; Process for increasing the solubility of potash in —. E. Anderson, Assignor to International Precipitation Co., Los Angeles, Cal. U.S. Pat. 1,249,708, Dec. 11, 1917. Date of appl. Mar. 14, 1917.

THE cement dust is exposed to the action of steam under pressure and at a temperature above $100^{\circ}\text{C}.$ so as to convert the difficultly-soluble potash into a more soluble form. The product is then leached with water to extract the potash.—A. B. S.

Thorium; Recovery of — [from monazite sand] as pyrophosphate. Welsbach Co., Gloucester City, N.J., Assignees of M. A. Goltz, Winona, Minn., U.S.A. Eng. Pat. 112,380, June 14, 1917. (Appl. No. 8550 of 1917.) Under Int. Conv., Feb. 28, 1917.

THORIUM is obtained from monazite sand as pyrophosphate by treating the sand with concentrated sulphuric acid, heating the mass to a sufficiently high temperature to convert the orthophosphoric acid into pyrophosphoric acid, and treating the product with water. The pyrophosphates of the other rare earths remain in solution, and the insoluble thorium pyrophosphate, which contains small amounts of impurities, can be separated by decantation, filtration, etc.—F. Sp.

Lime mud [from ammonia-soda process]; Process of recovering values from —. H. A. Galt, Akron, Ohio, Assignor to Columbia Chemical Co., Barberton, Ohio. U.S. Pat. 1,249,739, Dec. 11, 1917. Date of appl. Feb. 5, 1915.

LIME mud from the ammonia-soda process, whilst heated and under pressure, is passed into a tank to allow the steam to escape. The solid portion is dried, heated, and crushed, to produce a fertiliser, and the liquor is evaporated to obtain salts.

—F. Sp.

Cyanogen compounds; Process of making —. H. Philipp and H. Foersterling, Perth Amboy, N.J. U.S. Pat. 1,249,821, Dec. 11, 1917. Date of appl. June 4, 1912. Renewed May 11, 1917.

A METAL capable of forming cyanogen compounds is vaporised from a molten mass containing it, and the vapour is led into a separate chamber where it reacts with nitrogenous and carbonaceous matter; or the metal may be vaporised in a current of nitrogen, and the mixture of vapour and nitrogen led into a retort containing carbonaceous matter.—F. Sp.

Molybdenum compounds; Process of obtaining —. E. H. Westling (Assignor to N. W. Stern) and E. Anderson, San Francisco, Cal. U.S. Pat. 1,250,063, Dec. 11, 1917. Date of appl. Oct. 9, 1916.

MOLYBDENUM is separated from solutions containing molybdic acid by adding a salt of a trivalent metal, e.g., iron, then adding an alkaline basic compound, if necessary, to neutralise the acidity and precipitate the molybdate of the trivalent metal, separating the precipitate, and digesting it with a soluble base, to produce a molybdate of the latter.—F. Sp.

Iodine; Process for the direct extraction of — from fresh or dried marine algae. V. Vincent, Quimper, France. U.S. Pat. 1,249,863, Dec. 11, 1917. Date of appl. Dec. 26, 1916.

Method and apparatus for separating gases and the formation of products thereby. Eng. Pat. 112,153, See I.

VIII.—GLASS; CERAMICS.

Chemical glassware; Comparative tests of —.
P. H. Walker and F. W. Smither. J. Ind. Eng. Chem., 1917, 9, 1090—1092.

COMPARATIVE tests were made with five brands of American glassware and with specimens of Jena and Kavalier glass beakers and flasks. In the evaporation test, sodium chloride solution was repeatedly evaporated to dryness in the beakers. In no case were cracks produced after 12 evaporations. The beakers were also tested for extremes of temperature by filling them with cold water, which was then heated rapidly to boiling, and by plunging them into ice-water when filled with boiling water, and paraffin oil at 150° C., and at 200° C. As a shock test they were dropped bottom downwards upon a thick board from heights increasing by 5 inches. Solubility tests included boiling water in the beakers for 24 hours, and leaving it for 72 hours, and in the flasks boiling the water for 5 hours, and leaving it for 17 hours. Solutions containing sodium chloride and nitrate were mixed with a large excess of sulphuric acid, and boiled and heated for an hour after fumes of sulphur trioxide appeared. In the case of $N/2$ solutions of sodium and potassium carbonates and hydroxides the boiling was continued for 20 mins., and fresh solutions were subsequently evaporated in the same beakers. Strong ammonia solution was allowed to stand for 24 hours in the vessel, and then diluted and boiled for 30 mins., whilst 2*N*-solutions of ammonium chloride and sulphide were left for 24 hours and then boiled for 30 mins. The results, given in tabular form, showed that the American glassware was superior to Kavalier and equal or superior to Jena ware for laboratory purposes.—C. A. M.

PATENTS.

Crucibles for preparing fused quartz. Method of preparing crucibles for preparing fused quartz.
F. G. Keyes, Boston, Mass., Assignor to Cooper Hewitt Electric Co., Hoboken, N.J. U.S. Pat. (A) 1,249,636 and (B) 1,249,637, Dec. 11, 1917. Dates of appl., (A) July 1, 1913, (B) Apr. 8, 1915.

(A) A CARBON crucible is provided with a lining of tungsten or other refractory metal which is inert to fused quartz. (B) The lining is made by preparing a paste of sodium tungstate (or other suitable compound) and an appropriate binder, spreading this paste over the inner surface of the crucible, igniting the crucible and lining so as to harden the latter, and then applying a burnishing tool or roller so as to compress the lining and give to it a firm, tight, and compact surface.—A. B. S.

Plastic material. R. B. Ransford, London. From Soc. Française du Céramoïd, Paris. Eng. Pat. 112,196, Feb. 28, 1917. (Appl. No. 2971 of 1917.)

ZINC oxide is added in small quantities to a hot solution of gelatin or other similar material which solidifies on cooling, and a strong solution of calcium chloride, about 32° B. (sp. gr. 1.27), added while the temperature is prevented from rising above 60° C. A small quantity of sulphur may be added to make a more flexible material. The preferred proportions are anhydrous calcium chloride 10 parts, commercial zinc oxide 200 parts, glycerin 100 parts, washed sulphur 25 parts, gelatin or the like 2000 parts, water 1955 parts. A double oxychloride of zinc and calcium is formed within the gelatinous material. The material is specially suitable for moulding the heads and bodies of dolls, etc.—W. F. F.

Gas-fired furnaces for pottery and other purposes.
H. J. Yates, Birmingham, S. N. and E. R. Braysshaw, Manchester, Eng. Pat. 112,365, Apr. 28, 1917. (Appl. No. 6008 of 1917.)

ONE or both of the side walls of a rectangular gas-fired furnace is provided with a regenerative chamber, A, in direct communication with the interior of the furnace and heated by the waste

gases. The gas burners, D, D, are placed inside the regenerative chambers, preferably in pairs at the top and bottom. The other gas and air fittings, E, F, are outside the chambers and are therefore kept cool. Access to any burner is readily obtained. The floor is constructed of blocks, C, C, C, to carry the saggars or goods to be heated; between these blocks are channels C, C, through which pass the flames from the bottom burners. Refractory blocks, B¹, may be fitted into the outlet passages, a², so as to regulate the flow of the waste gases.—A. B. S.

Plastic composition [for retorts], and process of producing same. J. D. Hollingsworth and J. Mitchem, Kusa, Okla. U.S. Pat. 1,249,960, Dec. 11, 1917. Date of appl., Jan. 4, 1917.

A PLASTIC composition for use in manufacturing retorts consists of fireclay 36 lb., fireclay cement 59 lb., graphite 14 lb., and common salt 1 lb. The salt is dissolved in water and the other ingredients are mixed together in a dry state and then added to the salt solution, the whole being mixed to form a mass of the consistency of dough. The paste is allowed to stand for "a substantial period" and is then made into retorts.—A. B. S.

Enamels; Production of ground —. P. Eyer, Halberstadt. Assignor to R. Koepp und Co., Oestrich, Germany. U.S. Pat. 1,219,937, Dec. 11, 1917. Date of appl., July 21, 1915.

IX.—BUILDING MATERIALS.

Plaster and cement; Mechanism of the setting process in —. C. H. Desch. Faraday Soc., Jan. 14, 1918. [Advance proof.] 7 pages.

THE rival hypotheses of the setting processes are examined and compared. Le Chatelier's theory of the setting of plasters (this J., 1888, 675) is regarded as corresponding closely with the facts, but attention is drawn to the possibility that it is not quite complete, as indicated by the work of Cloez (this J., 1903, 366) and Davis (this J., 1907, 727). The oxychloride and certain other cements set by a similar process, i.e., crystallisation of an insoluble compound from a solution of the component bodies. The hardening of lime mortar

is a simple process of desiccation followed by carbonation. The setting of Portland cement is a more complex problem. Le Chatelier (this J., 1888, 847) holds that the mechanism is similar to that in the case of plaster. There is the alternative hypothesis, originally due to Michaelis (see this J., 1909, 836), that amorphous and gelatinous products are formed, the gradual desiccation of which leads to hardening of the cement. Further light has been thrown on the problem by the work of the U.S. Bureau of Standards (see this J., 1916, 1016) on the setting of the individual constituents, from which it appears that the physical nature of the hydrated product may depend on the concentration and so on the amount of water present. In practice the amount of water is restricted and favours the production of gelatinous substances, whereas in Le Chatelier's experiments water was in excess, whereby crystallisation was favoured.

—H. J. H.

Portland cement; The setting and hardening of — G. A. Rankin. Faraday Soc., Jan. 14, 1918. [Advance proof.] 6 pages.

THE author summarises the findings of the U.S. Geophysical Laboratory and the Bureau of Mines on the nature of the chief constituents of Portland cement and their influence on the setting process. The essential components of the clinker are CaO , Al_2O_3 , and SiO_2 , and a good cement can be made from the three pure oxides. In commercial cements other and minor constituents are present, but their influence on the setting is purely secondary. The study of the above mentioned ternary system shows that in a well-burned clinker three compounds are capable of a stable existence, viz., $2\text{CaO}.\text{SiO}_2$, $3\text{CaO}.\text{SiO}_2$, and $3\text{CaO}.\text{Al}_2\text{O}_3$. If the time and temperature of heating are insufficient, then free lime and $5\text{CaO}.3\text{Al}_2\text{O}_3$ are also present. All these compounds have been identified in commercial clinkers and the first three form 90% of the whole. The hydration of the separate compounds was studied. Lime hydrates to an amorphous product which later crystallises. $5\text{CaO}.3\text{Al}_2\text{O}_3$ with a little water sets rapidly, but disintegrates with excess, partly owing to dissociation and partly to its considerable solubility in water. $3\text{CaO}.\text{Al}_2\text{O}_3$ with water, sets and hardens rapidly, but the product has little strength in water, being comparatively soluble. Probably there is first formed an amorphous hydrate which crystallises later. $2\text{CaO}.\text{SiO}_2$ sets only after several months, but the product is not very soluble. Free lime is leached out by water, gelatinous silica being left. If sufficient water be taken, the decomposition can be carried to completion—a process which is accelerated by the presence of $3\text{CaO}.\text{Al}_2\text{O}_3$. $3\text{CaO}.\text{SiO}_2$ with water, sets and hardens rapidly, giving a product of strength comparable with that of good Portland cement. This compound is the essential constituent of a good cement, which contains 30–35% of it. On hydration, free lime is extracted, leaving gelatinous hydrated silica, just as with the dicalcium silicate, but the decomposition is more rapid and can be carried to completion if washing is continued. From these observations it seems that the setting and hardening of cement involve the formation of gelatinous hydrated material which subsequently partly crystallises. The initial set is probably caused by hydration of the tricalcium aluminate. This and hydration of the tricalcium silicate are responsible for the hardness and cohesive strength at first. The gradual increase of strength is due to the continued hydration of these and of the dicalcium silicate. Gelatinous silica is probably the chief cementing material, just as it appears to have formed the original binder of sand grains in tough sandstones, which are ideal concretes.—H. J. H.

Portland cement; Constitution and hydration of — A. A. Klein. Faraday Soc., Jan. 14, 1918. [Advance proof.] 9 pages.

PROGRESS towards a solution of the problem of the constitution of cements dates from the application of the microscope and optical methods by Le Chatelier and Tornebohm. Three main theories of constitution have held the field, viz., that cement is (1) a mutual solid solution of various constituents of disputed composition, (2) a definite compound of lime, silica, and alumina, and (3) a mixture of separate silicates and aluminates, some or all of which are hydraulic. The probability of the third view has been established by the work of the United States Geophysical Laboratory (see this J., 1915, 139; 1916, 842) and Bureau of Standards (this J., 1916, 1016). The former studied the equilibrium relations of the ternary system, CaO , SiO_2 , Al_2O_3 , and the latter applied the results to typical cement clinkers. Within the composition limits of good practice Portland cements are essentially a mixture of $3\text{CaO}.\text{SiO}_2$, $3\text{CaO}.\text{SiO}_2$, and $3\text{CaO}.\text{Al}_2\text{O}_3$. The hydration of the individual constituents was studied so that conclusions could be drawn as to the mechanism of the setting of cement. The aluminate hydrates rapidly and probably causes the initial set. Compounds of aluminate and calcium sulphate may be formed, and free lime, if present, is hydrated. Next the tricalcium silicate is hydrated and this process continues for about one month, producing a mass of dense structure. The dicalcium silicate hydrates to a granular porous mass. Neither should predominate in good cement. It is possible by grinding together the previously burned constituents in suitable proportions to make a mixture having the properties of Portland cement.—H. J. H.

Cements; Crystalloids against colloids in the theory of — H. Le Chatelier. Faraday Soc., Jan. 14, 1918. [Advance proof.] 4 pages.

THE author holds that explanations of hardening which state that the cement is colloidal are meaningless. Colloids are only insoluble bodies in a state of extremely fine division, which imparts to them a relatively high surface energy, and this gives rise to a number of special properties associated with the colloidal state. Soluble bodies cannot persist in the colloidal condition in presence of a liquid capable of partially dissolving them, owing to progressive recrystallisation and growth of crystals. In the setting of hydraulic cements it is possible that the particles, in the initial stages of the set, are in the colloidal condition just as are many precipitates, e.g., barium sulphate, but there is no proof that this persists, even though the particles in the hardened cement are not recognisable as true crystals. Probably they are too small to be detected. The conditions of setting are such that the growth of the particles is limited, but it is possible to choose conditions such that the cements on hydration form visible crystals. The author does not see any reason to discard his original theory (this J., 1888, 817) that the anhydrous cement dissolves, to form an aqueous solution supersaturated with respect to the hydrated compounds. These crystallise out in a confused mass, thus giving to the product its mechanical strength.—H. J. H.

Cement; Setting of — J. G. A. Rhodin. Faraday Soc., Jan. 11, 1918. [Advance proof.] 2 pages.

IN experiments to render soluble the potash in felspar, the latter was heated with lime and salt. The residue after leaching with water had setting properties, especially after heating it with more lime. Some cements of this and other origins can lose their setting properties completely on standing

in a stoppered bottle for 24 hours. They can be prevented from acquiring this inert form by the addition of 0.5% of aluminium sulphate. Cements also become inert after fusion. An active cement is in a state of "labile molecular equilibrium."

—H. J. H.

Portland cement: Effect of addition of suitable slag on setting properties of —. E. Deny and E. H. Lewis. Faraday Soc., Jan. 14, 1918. [Advance proof.] 4 pages.

CEMENT clinker made from blast-furnace slag (hematite pig) and limestone, owing to the high alumina to silica ratio, usually gives a quick-setting cement. This can be corrected by the addition of a properly-ground slag, and at the same time, with up to 30% of slag, the tensile strength is increased. Experiments on the addition of slag (SiO_2 30.5%, $\text{Al}_2\text{O}_3 + \text{Fe}_2\text{O}_3$ 16.6%, CaO 49.4%, MgO 2.3%) to ordinary brands of Portland cement, gave similar results. Mixtures of 70% of cement and 30% of slag always showed increased tensile strength as compared with the neat cement at 7 days and 28 days, whilst the setting times—initial and final—and the expansion were generally diminished. By the addition of slag to a cement clinker made from blast-furnace slag, a cement has been produced with a strength of 1300 lb. at 28 days.—H. J. H.

Cement: Setting of — in relation to engineering structures. B. Blount. Faraday Soc., Jan. 14, 1918. [Advance proof.] 3 pages.

THE absence of precise knowledge of the mechanism of setting of cements—plaster of Paris excepted—is emphasised. The setting of the commoner and more important Portland cements is a slow and gradual process and it is not possible practically to treat the time of setting in a rigid quantitative manner. Furthermore, tests are usually made on cements neat, whereas in practice the cement is generally used in concrete and the setting times in the two conditions are not quantitatively related. Further investigation is advocated.—H. J. H.

Mortar: Ancient and modern —. W. J. Dibdin. Faraday Soc., Jan. 14, 1918. [Advance proof.] 5 pages.

IN work carried out for the Institute of British Architects, the author was able to compare the mortars used by builders in ancient and modern times. The former were not superior to properly compounded mixings of the present day. In modern practice 1 volume of lime is usually taken to 3 of aggregate, but 1 to 1 was the average proportion found in the old mortars examined. Whereas now clean washed sand is specified, in ancient mortars the aggregate was found to contain up to 19.5% of clay, the builders having used any convenient materials without any special care in selection. Experimental mixings showed that the ratio of 1 of lime to 2 of aggregate usually gives the strongest mortar and sometimes it is advantageous to incorporate a little clay. No evidence of the formation of soluble silicates to any appreciable extent could be found. The author believes that the mortar sets owing to a process of aggregation, without chemical combination; crystallisation also assists in the setting. Where the ratio 1 : 3 is adopted there is insufficient lime to fill the pores and mechanical weakness results.—H. J. H.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Wrought iron: Some unusual features in the microstructure of —. H. S. Rawdon. Technical Paper No. 37, Bureau of Standards, U.S. Dept. of Commerce. Engineering, 1918, 105, 77—79.

A WROUGHT iron eyebar which had been in use for 30 years as a tension member of a railway bridge revealed unusual features upon microscopical examination. In addition to the usual structure of wrought iron, the ferrite crystals had a peculiar mottled appearance which was restricted to certain streaks throughout the metal, and particularly associated with unusually large crystals. Using Stead's method of etching with an alcoholic solution of cupric chloride acidulated with hydrochloric acid, a structure consisting of broad parallel bands was seen across the elongated crystals, bearing some resemblance to twinned crystals, and also, more often, presenting an indefinite mottled appearance of light and dark areas; such patterns are not found on etching ordinary wrought iron. Fracture occurred through the crystals and parallel to the markings constituting the mottled pattern at that point, leading to the conclusion that the non-homogeneity of the individual crystals, as indicated by the mottled etch pattern, is due to some impurity—in this case phosphorus—dissolved in the iron but not uniformly diffused. The ill effects of phosphorus may be much increased in this way. Examination of a series of wrought irons showed that such features are not common, or characteristic of all low-grade irons, which may be unsuitable for other reasons. A second type of markings—the well-known Neumann lines—are shown to bear no apparent relation to the other variations in structure described.—T. H. B.

Carbon steels: Anomaly of elasticity of — and the reversible transformation of cementite. P. Chevenard. Comptes rend., 1918, 166, 73—76.

ON the analogy of the nickel-steels there should be an anomaly in the elasticity of the carbon steels corresponding to the magnetic transformation and to the anomaly in the dilatation of the cementite (see this J., 1917, 882). This was investigated by measuring the variation with temperature of the torsional rigidity of three steels containing up to 1.5% of carbon. A torsion pendulum was employed made of wire from the steel under test, and at different temperatures maintained by an electrically heated furnace. At each temperature it was necessary to measure the time of oscillation of the pendulum and, by determining the elongation, the decrement of the torsion modulus. The wires had all been subjected to the same heat and mechanical treatment. It was found that the variation with temperature of the inverse squares of the times of oscillation only represents the apparent variation of the torsion modulus up to 300°C. Above 300°C. the decrements showed a rapid increase. The curves of the torsional rigidity showed a slight discontinuity at 210°C. indicating the Curie (magnetic transformation) point of cementite. The anomaly in the elasticity of carbon steels is directly proportional to the carbon content.—H. J. H.

Manganese in steel; Determination of — in the presence of chromium and vanadium by electro-metric titration. G. L. Kelley, M. G. Spencer, C. B. Illingworth, and T. Gray. *J. Ind. Eng. Chem.*, 1918, 10, 19—23.

MERCUROS nitrate was the only reducing agent found which would reduce permanganate quantitatively and rapidly at ordinary temperatures without reducing chromates and vanadates. A standard solution is made by dissolving 10.5 grms. of mercurous nitrate in 150 c.c. of water and 2 c.c. of nitric acid. The clear liquor is decanted off and made up to 1 litre. This solution is compared electrometrically with a solution of potassium permanganate containing 0.5 gm. of manganese per litre and standardised against sodium oxalate. The titration is made in a solution of 50 c.c. of sulphuric acid (sp. gr. 1.58) in 200 c.c. of water. The apparatus has been described previously (see this J., 1917, 1011). For the determination of manganese in steel, either sodium bismuthate or ammonium persulphate may be used as the oxidising agent. Using sodium bismuthate, the oxidation is carried out as described by Blair ("The Chemical Analysis of Iron," 7th Edn., p. 122). After filtering, a small piece of ice is added and 50 c.c. of sulphuric acid (sp. gr. 1.58). The volume should be 250 c.c. and the titration should not be performed above 40° C. Using ammonium persulphate, 0.5 gm. of the steel is dissolved in 65 c.c. of sulphuric acid (sp. gr. 1.58) and when solution is complete, nitric acid is added, drop by drop, to oxidise. After boiling a minute or two, the solution is diluted with hot water to a volume of 200 c.c., heated to boiling, and 10 c.c. of silver nitrate solution (2.5 grms. per litre) and 20 c.c. of ammonium persulphate solution (100 grms. per litre) added. Boiling is continued for about one minute, the solution cooled and titrated at about 20° C. after the addition of a little more sulphuric acid. Using this method, filtration is avoided and it is not necessary to make the titration at once as when using sodium bismuthate. Neither method requires special skill for its application. The authors discuss the reaction between permanganic acid and mercurous nitrate.—L. A. C.

Steel; Electrolytic pickling of —. M. De K. Thompson and F. W. Dodson. *Met. and Chem. Eng.*, 1917, 17, 713—714. (See also this J., 1917, 1097.)

COMPARATIVE experiments were made on the chemical and electrolytic pickling of black sheet iron and transformer sheet iron containing silicon. Electrolytic pickling gave a silvery white, clean surface much better than the spotted surface of the chemically pickled sheets. The amount of iron dissolved from the black sheet was 0.0032 gm. and 0.00386 gm. respectively per sq. cm. of surface. Another advantage of electrolytic pickling is the low temperature of working. The acid consumption is in proportion to the iron removed and the difference is not sufficient to be decisive. The presence of ferrous sulphate in the cell had no depolarising effect.—H. J. H.

Bismuth [in copper]; Colorimetric determination of —. H. A. B. Motherwell. *Eng. and Min. J.*, 1917, 104, 1091—1092.

The following method is suitable for the determination of small quantities of bismuth in copper. A suitable quantity of the copper is dissolved in nitric acid, the solution diluted and cooled, sodium carbonate is added to precipitate a small quantity of copper, and, after 6 hrs., this precipitate (which will also contain all the bismuth present) is collected on a filter. The precipitate is dissolved in hydrochloric acid, the copper and bismuth are precipitated as sulphides, which are collected,

washed until free from iron, and then dissolved in nitric acid. Five c.c. of lead nitrate solution (13.5 grms. per litre) is added to the solution, the mixture is nearly neutralised with ammonia, and an excess of ammonium carbonate is added. After boiling and cooling, the precipitate is collected, dissolved in nitric acid, and the precipitation repeated. If the colour due to copper is strong, dilute cyanide solution is added until the coloration has nearly disappeared and the precipitate then washed free from copper. The precipitate is dissolved in a very small quantity of nitric acid, the solution evaporated to a syrup, cooled, dissolved in 3 drops of nitric acid and 5 c.c. of water, the solution diluted to 25 c.c. and made up to 50 c.c. by the addition of 1.7% potassium iodide solution. The coloration obtained is compared at once with that given by a known quantity of bismuth in the presence of lead under similar conditions. The same quantity of lead nitrate solution must be present in the test and comparison solutions.—W. P. S.

Manganese ores in Sweden; Utilisation of —. J. Harden. *Met. and Chem. Eng.*, 1917, 17, 701—704.

THE Swedish consumption of manganese compounds is equivalent to about 6000 tons of manganese per annum, and this could be covered without importation if the internal resources were developed. Ferromanganese has been usually produced in blast furnaces by smelting manganese and iron ores with charcoal. The loss of manganese in the flue gas is great and a high carbon content of the alloy is almost inevitable. These can be obviated by the use of electric smelting where power costs permit. Three-phase types of furnace with the neutral point under the hearth seem preferable and the iron should be added as scrap, not as ore. The power consumption is 8000—8500 kilowatt hours per ton of ferromanganese (80% Mn, 12% Fe, 6% C). The addition of solid ferromanganese to the Bessemer converter or open-hearth furnace is to be deprecated on account of loss by volatilisation and in the slag. When solid ferromanganese is added to the metal in the ladle there is insufficient time for complete admixture and irregularity in the ingot may occur. To avoid these difficulties the alloy should be added after fusion and for this purpose an electrical melting furnace is well suited. The heat balance is given for a 3-ton arc furnace used for this purpose, showing a thermal efficiency of 40.4% and a cost of 21s. 10d. per ton of ferromanganese melted. Induction furnaces are still more economical of power. The manganese losses in melting are negligible. Comparative tests of the manganese losses in the addition of solid and liquid alloy to the steel show a saving of 44% in favour of the use of the molten alloy. Moreover, greater uniformity of the ingots produced is secured and the time of operation is reduced.—H. J. H.

Manganese deposits; Utilisation of low-grade —. J. E. Johnson, jun. *Engineers' Soc. W. Pa.*, Nov., 1917. *Eng. and Min. J.*, 1917, 104, 1027—1030.

FOR several years practically no manganese was produced in the U.S.A., the deposits, though considerable, being mostly low-grade. Spiegeleisen was mostly used in Bessemer converting, but the development of the open-hearth process brought about the use of ferromanganese, which is poor in carbon and hence produces low-carbon steel. The production of ferromanganese requires high-grade ores low in iron, phosphorus, and silica. Low-grade ores are as a rule refractory to concentration because the oxides are finely disseminated through the gangue. In the blast furnace, the silica combines much more readily with manganese than

with ferrous oxide; at higher temperatures the reduction is more complete but manganese is lost by volatilisation. A smelting loss of 15% is a minimum. The electric furnace is being introduced in the U.S.A. for the manufacture of ferromanganese. Less fuel is used, hence less silica is introduced, than in the blast-furnace; moreover, the silica is largely reduced to silicon, forming ferrosilicon-manganese, which takes up much less carbon than ferromanganese. Ferrosilicon cannot be used as a substitute, as it has a much weaker deoxidising power; calcium-silicon and calcium-aluminium-silicon are said to have been used in Europe. By altering existing blast-furnace practice so as to produce pig iron containing 1–2% of

destructive distillation of Canadian resinous wood waste, if twice the normal proportion (i.e., 20%) was used. Addition of 4 lb. of caustic soda per ton of slime gave a great improvement in extraction and grade of concentrate. Coal tar creosote was found to be indispensable as a collecting agent, but it could be replaced in part by hardwood oil. Attempts at utilising the whole crude oil distillates from the destructive distillation of Canadian resinous woods were unsuccessful. The successful hardwood oils were tried on a commercial scale, and extractions 20% higher than those found in the laboratory tests were obtained. The results tabulated below prove that the oils named can be used in practice instead of pine oil.

Frothing agent.		Collecting agent.		Oil mixture, lb. per ton ore.	Tons of ore treated.	Average extraction.
		Coal tar creosote.	Coal tar.			
Pine oil G.N.S. No. 5	20	60	20	0.98	1994	86.8
ditto	20	60	20	0.98	2019	88.3
Heavy hardwood creosote	40	50	10	1.06	807	87.4
Hardwood acid creosote oil	40	50	10	1.06	675	89.1
Ketone residue	25	65	10	1.06	739	88.5

—W. R. S.

manganese from a mixture of iron and low-grade manganese ores, the present shortage of manganese could be partly overcome. This can also be attained by charging low-grade manganese ore into the open-hearth furnace, a substantial reduction to metal being caused by the metalloids in the bath.—W. R. S.

Molybdenum in Norway. E. R. Woakes. Inst. Min. and Met., Jan., 1918. [Advance copy.] 12 pages.

MOLYBDENUM is chiefly mined in the part of Norway lying south of a parallel passing through Christiania. The deposits are of three types: quartz lodes, fissures in granite, and impregnated granite. There are only a few mines having a regular output, and the total export in 1916 is said to have been 140 tons of concentrate. The ores are crushed in Blake breakers and ball mills, and concentrated by the Ehnore vacuum process. Mica and copper pyrites constitute objectionable impurities. If the post-war price does not fall below 80s. per unit of MoS_2 , the Norwegian output of molybdenum may be maintained at about 100 tons per annum. It is probable, also, that ferro-molybdenum will be made in Norway in the near future.—W. R. S.

Flotation; Canadian wood oils for ore — R. E. Gilmore and C. S. Parsons. Canadian Chem. J., 1917, 4, 151–157, 180–187.

THE investigation was undertaken on account of the difficulty of securing an adequate supply of imported pine oil (longleaf southern pine) for the flotation plants at Cobalt, Ont., where it is used as a frothing agent, with coal tar creosote and coal tar as collecting agents. The standard oil mixture giving successful commercial results at Cobalt consists of pine oil 10, coal tar creosote 80, and coal tar 10%. Other oils were substituted for pine oil in the above mixture, and if 10% was unsatisfactory the percentage was raised. Similarly, substitutes were introduced for the coal tar creosote and coal tar. Successful frothing or collecting substitutes were then mixed and tested, a Janney testing machine being used. The results proved that the following were suitable frothing agents for Cobalt silver ore: Crude hardwood creosote oils; crude ketone residue (from the refining of grey acetate of lime); pine oil from the

Flotation [of ores]: Effect of addition agents in — H. M. Thornberry and H. T. Mann. Met. and Chem. Eng., 1917, 17, 709–713.

THE influence of a number of common inorganic salts on the concentration of a Missouri lead ore was studied in a small laboratory flotation machine. The ore contained 4.64% of lead. Three oils were used—a hardwood creosote, “Naval Stores flotation oil 17,” and cresylic acid. The action of sulphuric acid and alkaline-earth sulphates was to lower the extraction about 10% but without much effect on the grade of concentrate. The acid and normal alkali sulphates and the alums had little or no effect on the flotation. The effect of the sulphates of the heavy metals was usually small but was to lower the extraction. Cadmium sulphate exercised a powerful and injurious effect on both the extraction and grade of concentrate.

Commercial aspect of recovery of potash in pig iron manufacture. Chance. See VII.

Effect of addition of suitable slag on setting properties of Portland cement. Deny and Lewis. See IX.

PATENTS.

Steel; Manufacture of — Sir. W. G. Armstrong, Whitworth and Co., Ltd., and W. C. Rowden, Newcastle-upon-Tyne. Eng. Pat. 111,916, Dec. 20, 1916. (Appl. No. 18,248 of 1916.)

STEEL scrap is melted together with carbonaceous matter in a basic open-hearth furnace. The steel is then poured into an open-hearth acid or basic furnace, pig iron, scrap steel, or carbonaceous matter being added.—W. R. S.

Blast furnaces or steel furnaces; Processes or means for removing solid “metal bottoms” of — W. Riddle, Middlesbrough. Eng. Pat. 112,199, Mar. 5, 1917. (Appl. No. 3251 of 1917.)

IN removing the mass of metal known as a “metal bottom” which accumulates below the hearth of a blast furnace, the holes for the reception of blasting cartridges are formed by burning with an oxygen jet instead of by drilling. To obtain the initial “bite” on the metal, a pocket of clay or an open-ended metal tube containing small coal or other combustible material is applied to the

surface and ignited by a lamp with the aid of the oxygen blowpipe. The burning is then continued by the blowpipe.—W. F. F.

Steel; Producing — in side-blown converters. J. H. Hall, New York, Assignor to Taylor Wharton Iron and Steel Co., High Bridge, N.J. U.S. Pat. 1,249,075, Dec. 4, 1917. Date of appl. Mar. 17, 1914.

The charge subjected to lateral air-blowing contains silicon and manganese in such proportions that a fluid slag is produced which contains approximately 60 parts MnO to 40 parts SiO₂.—W. R. S.

Coating iron with brass; Process for —. T. A. Iyer, Seshadripuram, India. Eng. Pat. 112,045, Dec. 21, 1916. (Appl. No. 18,329 of 1916.)

BRASS is melted in a crucible with 2.5% of potassium ferrocyanide, the two are mixed together, and 2.5% of barium chloride is added. The iron article is polished, dipped into the molten brass, removed, and cooled. In a modification the potassium ferrocyanide and barium chloride are replaced by potassium ferricyanide and sal-ammoniac (ammonium chloride) in the same proportion.—W. F. F.

Galvanising iron and steel plates, sheets, and the like; Mode of "hot process" —. The White-inch Galvanizing Co., Ltd., and R. E. Ordidge, Partick, Eng. Pat. 112,220, Apr. 20, 1917. (Appl. No. 5550 of 1917.)

To galvanise iron or steel plates on one side only by the dipping process, the side which is not to be galvanised is coated with a paint made by mixing lithopone 12 parts, Paris white 4 parts, and pulp size 1 part, with water, and boiling to the consistency of milk. This coating prevents the adherence of the molten zinc.—W. F. F.

Iron and steel; Process of rust-proofing — by vapours containing phosphorus compounds. W. H. Allen, Detroit, Mich. U.S. Pat. 1,218,053, Nov. 27, 1917. Date of appl., Feb. 1, 1917.

THE metal is placed in a closed chamber into which phosphorus pentoxide vapour and steam are passed simultaneously.—W. E. F. P.

Puddling furnaces. J. J. H. Mackinlay, Shifnal, Salop, Eng. Pat. 112,179. (Appl. Nos. 1249, Jan. 25, and 10,665, July 25, 1917.)

IN a puddling or reverberatory furnace, a pre-heating chamber is provided on the opposite side of the hearth to that of the grate, and the iron is introduced into it through an air-locked chamber having an outer door and a door communicating with the preheating chamber. The air-locked chamber is provided with a travelling floor which may be moved into the preheating chamber with its charge; the inner door is then closed and the floor withdrawn, leaving the charge in the preheating chamber. The charge is preheated by the hot gases passing to the flue and is then pushed on to the hearth by a ram moving longitudinally through the chamber. The walls of the preliminary heating chamber and the head of the ram may be cooled by internal water pipes. The combustion gases may be used finally for heating a steam boiler or for preheating the air or gas used for heating the furnace.—W. F. F.

Heating-furnace; Metallurgical —. E. C. Walker and A. S. Moses, Assignors to G. M. Huges, St. Louis, Mo. U.S. Pat. 1,218,213, Nov. 27, 1917. Date of appl., Jan. 3, 1916.

IN a coal-fired furnace adapted to deliver dry heating gases under pressure to form a dry reducing atmosphere, the closed fuel chamber has a hopper casing at the top, from which fuel is supplied, and

an ash-pit at the bottom. Means are provided for maintaining air under pressure in the hopper in such manner as to form an air seal and also in the ash-pit; and for controlling the character of the dry reducing atmosphere by varying the amounts of air supplied to the hopper and the ash-pit.—W. E. F. P.

Furnace for treating ores. G. L. Tanzer, Seattle, Wash. U.S. Pat. 1,249,854, Dec. 11, 1917. Date of appl., July 24, 1917.

AN airtight metal cylinder, lined with refractory material, rotates on a horizontal axis. A perforated partition of refractory material is provided close to one end, forming a narrow gas compartment, and a grating is arranged parallel to the partition and nearer the centre of the chamber, forming a compartment for charcoal. Ore to be treated is placed in the remaining larger compartment and a fan is provided in a co-axial chamber within the lining of the opposite end of the casing, communicating by passages with the ore compartment. Gas is circulated by the fan through the gas compartment, charcoal compartment, and ore compartment to the fan chamber, and thence through a passage in the lining back to the gas compartment.—W. F. F.

Metal pipes, rods and the like; Apparatus for covering — with lead. Apparatus for covering the internal surface of metal pipes and the like with lead. J. A. Reavell, Beckenham, Kent, and W. J. May, London, Eng. Pats. (A) 112,321 and (B) 112,322, Jan. 9, 1917. (Appl. Nos. 393 and 394 of 1917.)

(A) THE external surface of a pipe or rod is "tinned" with an alloy of tin and lead, and the pipe or rod is mounted with its axis vertical in a concentric casing, and supported by guides and by a sliding collar at the lower end, so that it may be moved vertically through the casing. An annular polished die is arranged in the casing, surrounding the pipe or rod, and slightly spaced from it, so that when molten lead is poured into the upper part of the casing, it solidifies in the annular space between the die and the pipe. The lower part of the casing is surrounded by a water jacket so that the coating of lead solidifies as the pipe is drawn downwards, and the upper part of the casing is heated, preferably by gas rings, to keep the lead molten. (B) The apparatus is similar to that described in (A) except that the pipe is coated internally and itself forms the container for the lead. A polished internal cylindrical die is used, slightly smaller than the pipe, and the pipe is heated by an external gas-ring above the die and cooled by a water jacket at the lower end of the die.—W. F. F.

Zinciferous ores; Treatment of —. J. H. and P. M. Gillies, East Camberwell, Victoria, Australia. Eng. Pat. 112,336, Feb. 1, 1917. (Appl. No. 1633 of 1917.)

COMPLEX zinc ore containing also lead, copper, arsenic, antimony, gold, and silver, is coarsely crushed, and partly desulphurised by roasting, then mixed with carbonaceous material, preferably coke, and about 20% of water, and fed to a fuming furnace having a perforated grate through which a low pressure air blast is supplied. Zinc and lead are volatilised and drawn off mainly as zinc oxide and lead sulphate, and condensed together with arsenic and antimony impurities. The clinker remaining in the furnace, containing the non-volatile metals, is smelted in an electric furnace with the necessary flux to form a matte and any residue of zinc and lead which is driven off is also condensed. The condensed compounds are treated with sulphuric acid to dissolve the zinc oxide and arsenic and antimony compounds, and the lead

sulphate is then allowed to settle out. The solution is heated to about 80° C., and treated with hydrogen sulphide to precipitate the impurities as sulphides, which are then filtered off. If cadmium is present it is removed prior to the treatment with hydrogen sulphide by passing the solution over granulated zinc. The purified zinc sulphate solution is electrolysed with zinc cathodes and lead anodes, until the amount of liberated sulphuric acid reaches 10—12%, and the liquor may be used for treatment of a further charge of condensed fume. To secure an even deposition of zinc, about 0.5—1.0 gm. of gum arabic may be added per litre of solution.—W. F. F.

Zinc-extracting furnace with vertical retorts. R. von Zelewski, Engis, Belgium. U.S. Pat. 1,250,071, Dec. 11, 1917. Date of appl., Feb. 21, 1917.

A CASING is provided with a vertical cylindrical chamber for the retort, and contains gas and air ducts communicating with the chamber. The chamber is open at the bottom, and the retort is supported on a platform, movable vertically, which is counterbalanced by weights attached to cables running over pulleys, and which closes the bottom of the chamber.—W. F. F.

Spelter; Process for producing —. C. H. Fulton, St. Louis, Mo., Assignor to Metallurgical Laboratories, Inc., Chicago, Ill. U.S. Pat. 1,249,061, Dec. 4, 1917. Date of appl., Jan. 22, 1917.

FINELY divided spelter or zinc dross is mixed with coke and tar or pitch and compressed into briquettes that will retain their original form and volume when submitted to zinc distillation temperatures.—W. R. S.

Amalgamating and other apparatus; Agitators for use in —. S. L. Berry, San Francisco, Cal., U.S.A. Eng. Pat. 112,405, Sept. 28, 1917. (Appl. No. 14,050 of 1917.)

By an amalgamating apparatus, pulp is fed into a tank containing mercury at the bottom, and a turbine pump casing is mounted concentrically on a vertical, positively driven shaft, and submerged in the liquid in the tank. The pump casing contains an impeller rotated independently, and has a flared suction inlet at the top for the pulp. The pulp is discharged through slots in radial pipes projecting outwards from the pump casing close to the bottom of the tank. The slots discharge into the mercury and are inclined slightly upward in the direction of revolution of the radial pipes. The direction of rotation of the impeller may be reversed when desired by means of a suitable bevel wheel reversing gear, to clear the slots when clogged. The pump casing is preferably driven through a belt passing over cone pulleys, so that the relative speed of casing and impeller may be varied.—W. F. F.

Case-hardening material; Process of making —. A. O. Blach, Assignor to A. O. Blach Co., Chicago, Ill. U.S. Pat. 1,248,604, Dec. 4, 1917. Date of appl., Sept. 18, 1917.

THE process consists in shrinking and drying granular carbonaceous material at a temperature above 1000° F. (540° C.), then impregnating the granules with a "solution of an "energiser" infusible at the temperature employed, and mixing the impregnated granules with a pulverulent "energiser."—W. R. S.

Alloy; Metal — [for electrical contacts]. H. S. Cooper, Assignor to The Electro Metals Products Co., Cleveland, Ohio. U.S. Pat. 1,248,621, Dec. 4, 1917. Date of appl., Jan. 21, 1916. Renewed Oct. 8, 1917.

A HARD, ductile, malleable alloy for electrical contact devices consists of gold, silver, and approximately 4% of osmium.—W. R. S.

[Zirconium] alloy and process of producing same — J. B. Grenagle, Catonsville, Md. U.S. Pat. 1,248,648, Dec. 4, 1917. Date of appl., Dec. 7, 1915.

AN iron-zirconium alloy containing 60—90% of the latter is prepared from materials containing iron and zirconium by the aluminothermic method.—W. R. S.

White metal alloy. H. K. Sandell, Assignor to H. S. Mills, Chicago, Ill. U.S. Pat. 1,248,925, Dec. 4, 1917. Date of appl., June 18, 1917.

THE alloy is composed of mercury 10, bismuth 10, tin 10, zinc 20, and copper 50 parts by weight. A primary alloy is first made by melting the bismuth and tin together, cooling the mixture to just above its melting point, and adding the mercury. This is then added to the molten zinc, and the product to the molten copper, each of the last two metals being maintained at its melting temperature.—W. E. F. P.

Metallic [arsenical] ores; Apparatus for treating —. W. R. Smith, Buffalo, N.Y. U.S. Pat. 1,249,226, Dec. 4, 1917. Date of appl., Feb. 18, 1914.

THE apparatus consists of a blast furnace connected at the upper part with a long horizontal pipe into which the gases are drawn by means of a fan; and at the lower part with an enclosed bed upon which the molten metal is discharged. Means are provided for introducing water into the horizontal pipe and collecting the particles precipitated therein, and for supplying water to the bed enclosure for the purpose of condensing the arsenical fumes evolved from the molten metal.—W. E. F. P.

Flotation separation [of ores]; Apparatus for —. C. F. Spaulding, Salt Lake City, Utah. U.S. Pat. 1,249,681, Dec. 11, 1917. Date of appl., Feb. 11, 1916.

THE pulp container is provided with a vertical air-lift column to which compressed air and oil are fed at the lower end. A number of rotating vertical shafts are arranged in the column, rotating in the same direction, and each carrying a number of beater arms.—W. F. F.

Electrodeposition of metals; Apparatus for —. A. Leuchter, Brooklyn, N.Y. U.S. Pat. 1,249,787, Dec. 11, 1917. Date of appl., Oct. 5, 1916.

THE cathodes and anodes are suspended from suitable supports, provided with current connections, in a vertical position spaced from the inner walls of the electrolytic tank, and submerged in the electrolyte. A line of non-perforated pipe, arranged along the lower inner edges of the sides and ends of the tank, is connected to pipes supplying air, and to perforated pipes which are disposed closer to the vertical plane of the front face of the cathodes than to the adjacent faces of the anodes. Adequate quantities of air are thus discharged upwards through the spaces between the electrodes, and the electrolyte is kept in constant upward circulation, so that the impoverished electrolyte is moved from the cathode surfaces and caused to pass over to the back of the cathodes.—B. N.

Accumulators; Electric ——. I. Chkhar, Paris. Eng. Pat. 102,976, Dec. 29, 1916. (Appl. No. 18,611 of 1916.) Under Int. Conv., Dec. 29, 1915.

ELECTRODES for accumulators are made of a continuous band of metal formed from two sheets of rolled, drawn, or cast metal, with or without the interposition of a sheet of metal unattacked by acids, and thus forming a double surface electrode with a positive and negative surface. It is bent along its whole length so as to form on each of its surfaces alternate spaces or compartments, and the positive acting substance is placed in the compartments on one of the surfaces of the plate, and the negative substance in the alternating compartments on the opposite surface, the electrode being afterwards fixed in a suitable frame.—B. N.

Furnaces; Electric ——. G. B. Filmer and J. J. Denton, London. Eng. Pat. 112,177, Jan. 23, 1917. (Appl. No. 1116 of 1917.)

THE furnace is provided with a resistor and heater consisting of a normally non-conducting material, such as magnesia, sand, clay, or the like, which is ionised by the addition of a fusion mixture, such as sodium hydroxide and water, and removable electrodes are arranged within it. A muffle, tube, or plate, of fused zirconia or other suitable material, is partially or entirely enclosed in, or placed upon, the resistor material, and is utilised as a separate and independent heater when rendered conductive by the first heater.—B. N.

Furnace; Electric — for producing endothermic gas reactions. R. Pfähler, Charlotte, N.C., and I. Hechenbleikner, Great Falls, S.C., Assignors to Southern Electro-Chemical Co., Charlotte, N.C. U.S. Pat. 1,249,479, Dec. 11, 1917. Date of appl., Aug. 26, 1913.

THE opposite walls of the reaction chamber diverge from the base of the furnace upwards, each wall being provided with an opening, and a door mounted on a carriage and trolley. A pair of opposed electrodes are arranged in the chamber, one opposite each door, each electrode having a base member extending through and insulated from the furnace wall, and a removable diverging member attached to it, the diverging part conforming substantially to the contour of one of the diverging walls of the furnace chamber, and adapted to be withdrawn through the opening in the wall. Means are provided for circulating a cooling medium through the two members of each electrode. Two "kindling-blades" are associated with the electrodes, and separate nozzles are provided for delivering air into the furnace chamber, one of the nozzles being arranged to deliver a current of cooling air against the "kindling-blades," whilst a current of cooling air is also delivered through separate outlets directed laterally against the insulated portion of each electrode.

Anodes; Electrolytic ——. Electrolytic Zinc Co., Inc., New York, Assignees of H. M. Stuart, Baltimore, U.S.A. Eng. Pat. 108,311, July 12, 1917. (Appl. No. 10,072 of 1917.) Under Int. Conv., July 20, 1916.

THE anode, *e.g.*, of zinc-bearing metal, is surrounded by an envelope of material pervious to the electrolyte, but through which the slimes, etc., resulting from the disintegration of the anode will not pass, and certain portions of the anode surface are protected from electrolytic action by non-conducting shields, such as a pair of non-conducting strips, one on each side of the envelope. The shields thus divide the anode surface into distinct areas, and bear against the anode surface, so as to maintain a continuous tight fit of the envelope as disintegration proceeds, thus preventing the slimes produced during electrolysis from passing from one area to another.—B. N.

Battery plates; Storage ——. A. E. White, London. From U.S. Light and Heat Corporation, Niagara Falls, N.Y., U.S.A. Eng. Pat. 112,133, Sept. 22, 1916. (Appl. No. 13,483 of 1916.)

THE paste is composed of a mixture of lead oxides, such as crystalline and amorphous lead monoxide, and water, one of the oxides being of a weight (per unit volume) which is relatively a small fraction of that of the other.—B. N.

Commutator-section of cast alloy. H. K. Sandell, Assignor to H. S. Mills, Chicago, Ill. U.S. Pat. 1,248,924, Dec. 4, 1917. Date of appl., June 18, 1917.

A CAST commutator-section for use in dynamo electric machinery is made of an alloy composed of copper 95 and nickel 5%.—W. E. F. P.

XII.—FATS; OILS; WAXES.

Copra and other coconut products; Study of ——. A. J. Cox, Philippine J. Sci., 1917, A. 12, 49—53.

THERE are two large vegetable oil plants in the Philippine Islands, and several smaller ones are

in course of erection. In the tapahan (drying grill) method of drying copra, development of moulds and consequent deterioration of the copra is of frequent occurrence. Experiments have shown that the Californian method of treating deciduous fruits with the fumes of burning sulphur may be applied to the coconut. The nuts are opened and treated with the sulphur dioxide in a box to which only sufficient air to allow the sulphur to burn is admitted. They may then be kept for 2 weeks without moulds developing, and yield a very white copra, producing an oil free from rancidity and fully equal to the best Cochín oil. In the Manila markets, coconut oil is known as "Cebu sundried," "fair marketable Manila," and "Laguna," the first-named being worth about 2s. 6d. per 100 kilos. more than the Laguna grade. The distinction between these grades, however, is ill-defined, and it is suggested that the Government should subsidise good copra, and penalise smoked, dirty, mouldy, or imperfectly dried copra, in order to create a demand for the better grades. As the character of copra varies with the kind of nut and the district, it would be necessary to establish grades for different areas. These would be based not only on the proportion of oil, but also on the appearance, colour, and amount of moisture, the proportion of which may be roughly estimated by inspection by an expert.

—C. A. M.

Copra and coconut oil. H. C. Brill, H. O. Parker, and H. S. Yates. *Philippine J. Sci.*, 1917, A, 12, 55—86.

The exports of copra and oil from the Philippine Islands in 1916 were 72,277,164 kilos, and 16,091,169 kilos, respectively, the copra representing about a third of the world's output. Owing to its poor quality, however, Philippine copra fetches a lower price than any other copra on the market. The oil usually obtained from it is discoloured and rancid and contains from 5 to 20% of free fatty acids. Unless the moisture is reduced to about 6% immediately after opening the nuts, the copra is attacked by various micro-organisms, which reduce the yield of oil and deteriorate its quality. Samples of copra from various localities in the Philippines contained from 10.4 to 29.1% of moisture, and laboratory experiments showed that under the most favourable conditions for the growth of moulds (10 to 20% of moisture) there was a loss of 25% or more of the total oil present. If copra contains sufficient moisture for the growth of brown mould (*Aspergillus flavus*), a loss of 30 to 40% of oil may be anticipated. This species is frequently associated with black mould (*A. niger*), which only appears on copra containing at least 12% of moisture. It causes a pronounced loss of oil (sometimes over 40%), and increases the acidity of the oil, although not to the same extent as brown or white moulds. Where green mould (*Penicillium glaucum*) alone is present, there is but little loss of oil, but its presence indicates a proportion of moisture favourable for the development of the other moulds. The white mould (*Rhizopus* sp.) requires an atmosphere saturated with moisture, and then only develops on fresh copra, and is killed as soon as the drying process begins. Hence, although it grows rapidly and destroys a large proportion of oil, it is the least important of the four moulds. The amount of water is unevenly distributed in copra. For example, the total percentage may be as low as 5%, sufficient to inhibit the growth of moulds, whereas the upper layer invariably contains more moisture than the lower layer (e.g., 10.5 to 24%), or sufficient to support mould growth. If, however, copra has once been properly dried to contain not more than about 6% of moisture, it will not subsequently absorb sufficient moisture for moulds to develop,

unless it is kept for prolonged periods in air saturated with moisture. Both the spores and the mycelia of these moulds will survive exposure to 50° C. for 9 to 12 hours. Sun-drying produces an excellent grade of copra, but owing to rainy periods is chiefly used only in the southern islands. In other parts the tapahan or grill method is used. In this process the nuts are freed from husks, divided, and placed on bamboo rods beneath which shells and husks are burned. When partially dry the copra is removed from the shells and the drying completed. The finished product contains not less than 20% of moisture, and not infrequently 28 to 29%. Mechanical drying apparatus has not been introduced commercially into the Philippine Islands, largely owing to the belief that the current of heated air causes loss of oil. Experiments are described, however, which show that copra can be dried in a current of air at 70° to 100° C. without loss of oil. Apart from mechanical drying, however, much better products than are now usually put on the market could be obtained by a combination of the sun-drying and kiln processes carefully applied. Good copra should contain from 4 to 6% of water, and 65% of oil, calculated on the anhydrous substance, with an acidity of less than 1% (as oleic acid), and should be free from dirt and smoke. The cost of refining commercial coconut oil is estimated at 8 pesos (1 peso = 50 cents U.S.A. currency) for each 1% of fatty acids per ton of oil.—C. A. M.

Coconut oil; Methods for the production of pure — H. O. Parker and H. C. Brill. *Philippine J. Sci.*, 1917, A, 12, 87—94.

THE authors' experiments have shown that the oil cannot be readily expressed from freshly grated coconut, over 60% of the total oil remaining in the press-cake after being pressed at 1000 lb. per sq. in. By treating the material with water and live steam for 3 hours before expression, 80% of the total oil is removed by a single expression. The resulting emulsion when heated as in the native process always yields a coloured oil of burnt odour and taste, and no better results are obtained by heating the emulsion with salt, acids, or alkalis. The use of 10% sodium sulphite solution facilitates the separation, but the resulting oil is of inferior colour and taste. The treatment might be useful, however, for the manufacture of soap stock oils. The best method is to chill the emulsion for 24 hours at 15° C., which causes the water to separate, leaving an upper layer of solid fat and cellular tissue, and also checks the development of moulds. After removal of the water the solid layer is melted at a gentle heat, and passed through a filter-press, and the filtered oil sterilised for 30 mins. at 100° C. and stored in air-tight vessels. Oil thus prepared has a pleasant odour, is free from acidity or rancidity, and keeps much better than ordinary copra oil. Another method is to dry the shredded coconut in a current of air at 70°—85° C. until its moisture is reduced to 10%, which is sufficiently low to prevent the formation of emulsions. The material will then yield over 80% of its total oil in one expression. Commercial copra press-cake is used for stock foods and for fertilisers, but the product obtained by the method described is sufficiently pure for human consumption. Meal prepared from it had the following composition:—Water, 7.35; oil, 32.14; ash, 4.05; crude fibre, 37.12; and proteins, 20.34%. It might be used with advantage as a substitute for wheat flour and lard in the preparation of edible products.—C. A. M.

Coconut oil; Rancidity of Philippine — H. C. Brill and H. O. Parker. *Philippine J. Sci.*, 1917, A, 12, 95—110.

CERTAIN oils which are unmistakably rancid do not

restore the colour to decolorised magenta, whereas other oils which are not rancid give a coloration with the reagent. Hence no reliance can be placed upon the test as a criterion of rancidity, and the same applies to the test with diazobenzene-sulphonic acid. A high proportion of free fatty acids does not necessarily accompany rancidity. Distillation with steam removes rancidity, but does not cause pronounced change in the acidity, whilst neutralisation with alkali and washing with water removes the acidity but not the rancidity. There appears to be no definite relationship between the Reichert-Meissl value or the iodine value and the rancidity of coconut oil, but the proportion of soluble fatty acids shows indications of a relationship. The acetyl value may afford evidence of rancidity, but does not measure the degree of rancidity. Although a few samples of rancid oils gave low oxidisability values (this J., 1916, 898), the test appears to afford confirmatory evidence of rancidity, and where the value was high the oil was invariably rancid. Copra which has been attacked by moulds or copra with coconut milk adhering to it contains oxidising enzymes, some of which might be separated with the oil. Such enzymes, if present, would probably have considerable influence on the development of rancidity (see also this J., 1906, 381; 1910, 704, 1330).—C. A. M.

Castor oil used for lubricating aeroplane motors; Detection of foreign oils in —. C. Frabot. Ann. Chim. Analyt., 1918, 23, 7—11.

FURTHER investigation of the method described previously (this J., 1917, 1279), which depends on the relatively small solubility of castor oil in petroleum spirit and on the solubility of the petroleum spirit in the oil, shows that the character of the petroleum spirit used is of importance. The solubility of castor oil increases with the boiling point of the spirit; for instance, when the spirit is fractionated, the first fraction, b.pt. 33.2° C., dissolves 6.51 grms. of the oil under the conditions given (*loc. cit.*), whilst the last fraction, b.pt. 76° C., dissolves 13.0 grms. A fraction, b.pt. 184° C., obtained from ordinary motor petrol, dissolves 25.3 grms. of castor oil. The increase in volume of the oil due to dissolved petroleum spirit does not depend so much on the kind of spirit used; it varies from 10.5 c.c. with very light spirit to 18 c.c. with certain high-boiling fractions. It is therefore suggested that only the portion of petroleum spirit boiling between 35° and 65° C. be used for the test; with this spirit pure castor oil shows an increase in volume of 11.5 c.c. and the weight of oil dissolved is 8.85 grms.—W. P. S.

Sperm oils used for burning purposes; Characteristics of —. A. G. Blakeley and E. A. Reilly. J. Ind. Eng. Chem., 1917, 9, 1099—1100.

EXAMINATION of a large number of samples of genuine sperm oil, intended for burning in miners' safety lamps of the Davy type, gave results agreeing, in the main, with recorded values. Some of the constants, however, showed a wider variation than commonly accepted, viz.:—Refractive index (15.6° C.), 1.4619 to 1.4669. Fatty acids:—Sp. gr. (15.6° C.), 0.893 to 0.899; neutralisation value, 186.8 to 216.2; "titer" test, 6.2° to 13.6° C. Alcohols:—Iodine value, 63.9 to 74.1; m.pt., 20.0° to 27.0° C.; and saponification value of acetate, 189.5 to 216.0. The "flake-test," i.e., the temperature at which solid matter separated from the oil, varied from 38° to 50° F. (3.3° to 10.0° C.). Sperm oil containing from 1 to 4% of oleic acid caused a slight crust to form upon the wick of the lamp but otherwise gave satisfactory results in burning, but the addition of 6% made

the oil unsatisfactory. These results show that the injurious effect of free acids upon a lamp oil has been somewhat overestimated in the case of sperm oil. In judging as to the suitability of sperm oil as a lamp oil the iodine value and refractive index should be taken into account as well as the acidity and the other physical values.—C. A. M.

Wool-fat (lanoline) substitute and the preparation of cetyl alcohol. S. Axelrad. J. Ind. Eng. Chem., 1917, 9, 1123—1125.

SPERMACETI (20 grms.) is saponified with alcoholic potassium hydroxide solution, the alcohol evaporated, the soap dissolved in water, and the soap solution treated with excess of 10% calcium chloride solution. The calcium soap is separated, dried at 100° C., and distilled at 340° C. A cheaper method, which also gives a larger yield of cetyl alcohol, is to mix 20 grms. of calcium oxide containing about 5% of water with 15 grms. of melted spermaceti, and to heat the mixture, with occasional stirring, for about 6 hours. The mass is then cooled, water expelled at 100° C., and the temperature then raised to 340° C. for the distillation of the cetyl alcohol. The yield is over 40% of the weight of spermaceti, as compared with the theoretical yield of about 45%. The distilled cetyl alcohol is perfectly white and melts above 49.5° C. A copper still is preferably used for the distillation. Lanoline substitutes and cold creams may be made by mixing suitable proportions of a petroleum base with cetyl alcohol and water, and preferably with about 5% of lanoline to give the "unctuous" property of wool fat. A preparation suitable for pharmaceutical purposes consists of:—"Petroleum" base, 70; paraffin wax (m.pt. about 60° C.), 20; cetyl alcohol, 10; anhydrous lanoline, 10; and water, 100 parts. This preparation has the same properties as wool fat, and has the advantage of not becoming rancid.—C. A. M.

Basking-shark liver oil; Saturated hydrocarbons in —. M. Tsujimoto. J. Ind. Eng. Chem., 1917, 9, 1098—1099.

THREE genuine samples of the liver oil from the basking-shark (*Cetorhinus maximus*), the largest of the shark tribe, were pale yellow to orange liquids of low sp.gr., and contained 41.92 to 55.51% of unsaponifiable matter, in which the unsaturated hydrocarbon squalene (this J., 1916, 609; compare Chapman, this J., 1917, 392) was identified. One of the samples also contained about 10% of a yellow liquid saturated hydrocarbon, probably $C_{15}H_{32}$, which was not present in the other two samples. This sample had the following characters:—Sp. gr. at 15°/4° C., 0.8839; acid value, 1.09; saponif. value, 102.45; iodine value (Wijs), 178.3; refractive index at 20° C., 1.4773; and unsaponifiable matter, 41.92%. The unsaturated hydrocarbon, squalene, forms hexahydro-halides of the general formula, $C_{30}H_{50}.6HX$, which may be readily crystallised and serve for the identification of the hydrocarbon.—C. A. M.

Preparation of an edible fat and meat-extract substitute from bones. Kraus. See XIXA.

PATENTS.

Grating, "defibrating" or pulping machines [for coconuts and other oil-bearing products]. H. K. Reeves, London. Eng. Pat. 112,135, Sep. 27, 1916. (Appl. No. 13,744 of 1916.)

CELLULAR tissue of the coconut or other oil-bearing nuts is broken up and pulped by means of a rotating cylindrical drum, etc., the face of which

bears against the corresponding face of a curved grating plate, to which a reciprocating motion is communicated, e.g., by means of cam mechanism. The rear surface of the grating plate may also have prepared faces adapted to bear against prepared surfaces in the casing of the machine.

Utilisation of certain nuts or seeds in the manufacture of artificial butter or the like. Eng. Pat. 112,164. See XIXA.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber; Preparation, by the distillation and by the combustion of wood, of acid coagulants, and their effect on the quality of —. B. J. Eaton and G. S. Whitby. Agric. Bull. Fed. Malay States, 1917, 5, 124—131.

Pyroligneous acid prepared by the dry distillation of wood from the mangrove and the rubber tree, when used for the coagulation of latex, yielded a darker sheet or slab rubber than that produced by acetic acid, although in the case of crêpe the presence of a small proportion of sodium bisulphite permitted the formation of a pale product. A coagulant was also obtained by passing smoke from rubber wood in slow combustion through water and so extracting the soluble constituents. When used at the same concentration of acid for the coagulation of latex, the filtered "smoke solution" gave products of similar appearance to those obtained with the use of pyroligneous acid. In both cases, however, the rate of vulcanisation of the resulting slab or smoked sheet rubber was inferior to that of rubber obtained with simple acetic acid coagulation, the difference being more marked with the "smoke solution" product. The retardation of vulcanisation is attributed to the presence of phenolic substances and also of formaldehyde. Tests as to the effect of the addition of phenol or cresol to latex before coagulation with acetic acid showed a marked tendency to the formation of discoloured coagula, and the resulting smoked sheet rubber vulcanised more slowly than similar rubber produced in the absence of phenol or cresol; with slab rubber, however, the difference in rate of vulcanisation was inappreciable. The conclusion is drawn that although the smoke employed in the preparation of fine hard Para rubber may act as a preservative, it also has a bad effect on the rate of vulcanisation.—D. F. T.

Coagulation of latex in the presence of sugars. B. J. Eaton. Agric. Bull. Fed. Malay States, 1916, 5, 48—52.

IN reviewing the results of an investigation by Gorter and Swart of the West Java Rubber Testing Station and correlating them with the results of Eaton and Grantham, it is stated that the addition of sugar to latex aids coagulation by the bacterial formation of lactic acid, together with a smaller quantity of acetic acid and a trace of succinic acid. Lactic acid also plays an important part in the slow coagulation of latex with minimal quantities of acetic acid, the lactic acid in this case being produced by the action of micro-organisms on the sugars present in the latex. In order relatively to favour the growth of the lactic micro-organisms, it is necessary either to exclude air, or to add at least 0.2% of sugar, the former process checking the production of putrefactive and other bacteria, whilst the latter enables a sufficiently rapid production of lactic acid to inhibit the action of the other bacteria. The addition of 0.5 gm. of sodium bisulphite per litre

of latex does not interfere with the coagulation, using the additional 0.2% of sugar. Hydrofluoric acid, sulphuric acid, and alum are not recommended as coagulants, especially for making sheet rubber. Fermentation of the milk of young coconuts yielded a liquid containing a disappointingly low proportion of acetic acid, the action of the acetifying micro-organisms apparently having been inhibited by the formation of lactic acid.—D. F. T.

Rubber; Preparation of raw — with special reference to "slab" rubber and variability. B. J. Eaton. Agric. Bull. Fed. Malay States, 1917, 5, 183—188.

"SLAB" rubber as a substitute for sheet rubber possesses the advantage of greater rate of vulcanisation, increased uniformity in this respect, and superior tensile properties. There is no reason why the introduction of "slab" rubber should cause confusion or increase the difficulties of the manufacturer, and it will probably be advantageous to ship the rubber as "virgin slab."—D. F. T.

Rubber allowed to become damp; Development of chromogenic organisms in dry raw —. B. J. Eaton. Agric. Bull. Fed. Malay States, 1917, 5, 177—179. (See also this J., 1917, 1222.)

RUBBER despatched from the estate in a satisfactory condition is sometimes found to be affected with "spot disease" on arrival in London or other buying centres. The trouble is due to chromogenic organisms which develop in damp rubber, and it is now shown by experiment that the same development of coloured spots may occur in perfectly clean pale crêpe if this is wetted and rolled loosely, ten days being a sufficient period for a marked effect. Sheet rubber rolled into a cylinder direct from the sheeting machine and also "slab" rubber show no development of such pigment until they are cut, when the new surface becomes affected; thin crêpe which, whilst still wet, has been converted into thick or blanket crêpe is more liable to affection than original thick crêpe.—D. F. T.

Rubber; Effect of copper on crude —. C. P. Fox. J. Ind. Eng. Chem., 1917, 9, 1092—1093.

IN comparative tests in which sheet rubber was covered with discs of metal and exposed for several days at 150° F. (65.5° C.), Dewar found that copper had the greatest action owing to its promoting oxidation. His results were confirmed by Thompson and Lewis (this J., 1891, 717). In accordance with these observations a coating of copper for use in vulcanising rubber to iron has recently been superseded by a plating of other metals. In the author's experiments pieces of crude sheet rubber were treated with 1% aqueous copper acetate solution, copper acetate solutions containing 10% of acetic acid and 10% of ammonia respectively, and oil mixed with 1% of dry copper acetate. The duration of the experiments was about 3 months, and parallel tests were made in a bright light and in the dark. It was found that copper acetate will cause "tackiness" in crude rubber, the amount of action being proportional to the quantity of reagent and duration of contact, but not much affected by light or heat. The control samples of crude rubber ("pale plantation crêpe") were not changed in colour or texture when exposed to the light under the same conditions as the treated samples, and their behaviour affords an index of the value of this type of rubber. The presence of acetic acid had no material influence on the production of tackiness, but ammonia had a pronounced effect, producing a hard, cracked surface. The mixture of lubricating oil (containing

raneid vegetable oil) and copper acetate had a greater action on the rubber than the same oil by itself. This confirmed the observations of Weber ("Chemistry of Rubber") as to the action of cloth containing copper (used in dyeing) upon rubber used for waterproofing, especially when oil or grease is also present in the cloth.—C. A. M.

XV.—LEATHER; BONE; HORN; GLUE.

Tannin content of Pacific Coast trees. H. K. Benson and F. M. Jones. *J. Ind. Eng. Chem.*, 1917, 9, 1096—1098.

THE following amounts of tannin were extracted:—Western larch (*Larix occidentalis*), wood, 6.7; bark, 10.6; western yellow pine (*Pinus ponderosa*), wood, 8.9; bark, 10.9; western hemlock (*Isuga heterophylla*), wood, 1.0; bark, 10.93; dogwood (*Cornus nuttalli*), wood, 1.3; bark, 1.7; cottonwood (*Populus trichocarpa*), wood, 1.8; bark, 4.7; and alder (*Alnus oregona*), wood, 0.7; bark 3.3%. The wood extract of the western larch gives a pleasant, light red colour to the tanned hide. As the wood of this species also gives a high yield of alcohol when hydrolysed, this tree is more suitable for chemical utilisation than for timber. The tannin content of the western hemlock is equal to that of the eastern species. The bark has been regularly used by tanners on the Pacific Coast. The western pine, which is chiefly used for making boxes, yields a satisfactory amount of a good extract and the saw-mill waste of this species might be utilised in the manufacture of tannin extract. Of the deciduous woods the only one suitable for the manufacture of extracts is the dogwood. The extract could not be used alone for tanning, but might be employed as a red dye in conjunction with other tanning extracts. It was found that Douglas fir wood in slabs may be advantageously seasoned for a year before being used for the preparation of extracts. The effect of the hydrolysis, and, possibly, oxidation taking place during seasoning is to increase the amount of tannin (e.g., from 5.92 to 7.5%), to increase the total solids (e.g., from 14.92 to 15.8%), and to reduce the non-tannins (7.10 to 6.2%).—C. A. M.

Tanning [of fishing nets] and the study of tannins. W. Tombrock. *Chem. Weekblad*, 1917, 14, 1143—1150.

AN account of the methods employed by the Dutch fishermen for preserving their nets. The usual procedure is to immerse the net in a hot solution of tannin for some time, and then to dry it. The author has found that if the net is then immersed for 15 minutes in a solution containing 1% of copper sulphate and 0.7% of ammonia, and again dried, the durability is much increased. After this treatment, it is important for the net to be used for fishing as soon as possible. The method is also adapted to the preservation of other forms of netting.—A. J. W.

PATENT.

Leather-like material; Method of manufacturing —. A. G. Emery, New York, Assignor to Rubber Regenerating Co. U.S. Pat. 1,249,360, Dec. 11, 1917. Date of appl., July 14, 1916.

A MIXTURE of linseed oil and calcium rosinate is boiled until it is of a gelatinous consistency. It may be coloured if desired by incorporating American ochre and iron oxide, and the resulting product is used to impregnate fibrous material and is then oxidised. A solvent may be used to facilitate the impregnating process, and is then allowed to evaporate before the oxidation process. P. Sp.

XVI.—SOILS; FERTILISERS.

Soils; Movement of soluble salts through —. M. M. McCool and L. C. Wheeting. *J. Agric. Res.*, 1917, 11, 531—547.

EXPERIMENTS were carried out on moist soils in tubular containers, the short middle sections of which were filled with the soil and the salt to be studied, and the longer end sections with the soil alone. The containers were then closed, or left open if evaporation was to be studied, and placed in a closed thermostat at 18° C. It was found that soluble salts do not long remain localised but pass at a moderately rapid rate from regions of high to regions of lower concentration. When moisture is being lost by evaporation an upward movement of the salt takes place much more rapidly than any downward movement; this is especially marked in sandy soils. As the salts move through the soil, the soil solution changes in character, as a result of reactions between the salt and the soil particles as well as of diffusion. These changes may spread much farther than the soil mass receiving the application.—J. H. J.

Hawaiian soils; Reaction of — with calcium bicarbonate solution, its relation to the determination of lime requirements of soils, and a rapid approximate method for the determination of lime requirements of soils. M. O. Johnson. *J. Ind. Eng. Chem.*, 1918, 10, 31—33.

WHETHER lime is applied to the soil as oxide, hydroxide, or carbonate, the main reaction of the limed soil appears to be with calcium bicarbonate in solution. Absorption by soils from calcium bicarbonate solutions increases with the period of contact, approaching an equilibrium. With a decrease in the concentration of the bicarbonate solution, there is a decrease in the actual absorption, but an increase in the percentage absorption of the calcium bicarbonate in solution, indicating that at a certain concentration, absorption would be complete under prolonged contact with the soil. The total amount of calcium carbonate (expressed as % of wt. of soil) in the solution at the concentration at which absorption by a given soil is complete, expresses a definite absorptive capacity for that soil, and has been named the "minimum absorption." For mainland soils, the following procedure is recommended as a method of determining lime requirements. 200 c.c. of N/100 calcium bicarbonate solution is measured into a 500 c.c. Erlenmeyer flask and 10 grms. of the soil is added. The flask is shaken vigorously for 10 secs. The solution is filtered and 100 c.c. titrated with N/10 acid, using methyl orange as indicator. The difference in titration between 100 c.c. of the filtrate and of the original solution is proportional to the amount of calcium carbonate required by the soil. Multiplying by 10 the percentage of calcium carbonate required gives directly the tons of calcium carbonate per 2,000,000 lb. of soil, i.e., per acre.—L. A. C.

Acidity of soils; Determination of the — and its value in determining the quantity of lime to be applied in practice. J. Grantham. *Agric. Bull. Fed. Malay States*, 1917, 5, 138—149.

TRUOG's method (this J., 1916, 699) by which he determines the "active" and "latent" soil acidity and the avidity of the active acids, is considered to be the most satisfactory measure of the lime requirements of soils.—W. G.

[Soil] liming experiments. B. Bunting. *Agric. Bull. Fed. Malay States*, 1916, 4, 373—380.

THE results obtained from the growth of one or

at the most two crops of six different kinds of plants on one particular type of soil show that a decided improvement in crop production may be obtained by the application of lime in quantities not sufficient entirely to neutralise the acidity of the soil. The improvement in crop production is not directly proportional to the reduction of soil acidity. The author considers that one ton of quicklime per acre applied every four years will give the best return.—W. G.

Reverted phosphate. C. C. James. J. Ind. Eng. Chem., 1918, 10, 33—35.

EXPERIMENTS both on the laboratory and factory scale showed that the water-soluble phosphoric acid in acid phosphate (superphosphate) mixed with lime or calcium carbonate decreases on standing, the change being accompanied by a rise in temperature, which is greater with lime than with calcium carbonate. The decrease is more rapid at first, becoming slower on further standing. On trying the effect of the reverted phosphates on crops, it was found that it is just as valuable as the water-soluble phosphate when applied to sugar-cane on upland, ferruginous, clayey soils. Experiments upon rice with the reverted phosphate also showed favourable results.—L. A. C.

Bonedust : its adulteration with phosphate rock. C. E. Chapman. Dept. Chem., S. Australia, Bull. 9, 1917. 11 pages.

PHOSPHATE rock can be detected in bonedust by shaking the sample with Sonstadt's solution (a solution of mercuric and potassium iodides, sp. gr. 2.8). The bonedust floats, but 80 % of the rock phosphate sinks. For proper separation the tube containing the solution and sample of dust should be centrifuged for four or five minutes. The amount of tricalcium phosphate present in the material which floats in Sonstadt's solution can be determined in order to see if it complies with the legal standard of the country concerned. Finally the rock phosphate settling in the liquid can be examined microscopically.—W. G.

Calcium cyanamide : Determination of nitrogen in —. B. Turkus. Ann. Chim. Analyt., 1918, 23, 3—5.

ONE grm. of the sample is heated for 30 mins. with a mixture of 40 c.c. of concentrated sulphuric acid and 10 c.c. of water; the ammonia formed is then determined by distillation. If the sulphuric acid used is weaker or stronger than the concentration mentioned, the digestion must be prolonged for more than 30 mins. in order to decompose the cyanamide completely.—W. P. S.

XVII.—SUGARS ; STARCHES ; GUMS.

Sugars, starches, gums, proteins, and organic acids ; A precipitant for —. W. Schulte. Chem.-Zeit., 1917, 41, 822.

SUCROSE, invert sugar, dextrose, lactose, dextrans, and starch are precipitated from their aqueous solutions by ammoniacal lead acetate solution; gum arabic, gum tragacanth, albumin, casein, pepsin, peptone, and gelatin are also precipitated by the reagent. Whilst citric, tartaric, malic, tannic, gallic, and succinic acids, and pyrogallol are precipitated by lead acetate alone, benzoic, salicylic, and picric acids, and phenol yield precipitates only with ammoniacal lead acetate. The ammoniacal lead acetate solution must be freshly prepared (it readily absorbs carbon dioxide from the atmosphere) and is made by mixing 100 c.c. of saturated lead acetate solution with 26 c.c. of water and 8 c.c. of ammonia (sp. gr. 0.91). One part of gum arabic or phenol in 20,000 parts of water gives a turbidity or precipitate with the reagent; with sugars the minimum limit is about 1 part in 10,000 of water. The precipitates formed may be collected, washed with dilute ammonia, dried at 100° C., and weighed, or the precipitate may be ignited and the residual lead oxide weighed. The following factors are given for obtaining the quantity of substance present either from the weight of the precipitate or of the lead oxide :—

	Sucrose.	Gum arabic.	Phenol.
From weight of precipitate	0.1727	0.2564	0.2636
From weight of lead oxide	0.2386	0.3703	0.3125

Since glycerol is not precipitated by the reagent, the latter may afford a means of separating sugars, etc., from glycerol in the determination of this substance in wines, etc. Attention is directed to the fact that sugars are, to a certain extent, precipitated by basic lead acetate from their neutral solutions. In the clarification of saccharine solutions with basic lead acetate it is necessary, therefore, to add a small quantity of acetic acid if the solution is not already acid in reaction.—W. P. S.

Lime cake [calcium saccharate] analysis ; A quick method for —. A. N. Clark. J. Ind. Eng. Chem., 1918, 10, 51.

THE required weight of lime cake is weighed into a counterbalanced, nickel-plated, copper beaker of about 300 c.c. capacity, the calculated volume of acetic acid added from a pipette, and the mass mixed with a small pestle. A charge of basic lead acetate solution is added from a Sachs-Le Docte or Kruger pipette, the mass again mixed with a pestle, and poured on to a filter. This method is found to be much more rapid and less liable to loss by foaming and spilling, than the usual procedure. When the "free" sugar is to be determined, water is added in place of acetic acid.—L. A. C.

PATENTS.

Sugar cane ; Method of increasing the yield and reducing the production cost of —. C. F. Eckart, Oloa, Hawaii. U.S. Pat. 1,249,355, Dec. 11, 1917. Date of appl., June 25, 1917.

COVERED nitrate beds are established between the rows of canes, e.g., by applying lime compounds

or a mixture of organic matter with lime or calcium carbonate, and covering the spaces so treated with a dark-coloured, opaque, waterproof paper or fabric in contact with the ground.—J. H. L.

Molasses ; Manufacture of alcohol from — G. H. Hughes, London. Eng. Pat. 112,232, May 21, 1917. (Appl. No. 7324 of 1917.)

MEGASSE is mixed with molasses in the proportion of about 15 parts of fine, dry, screened megasse to 85 of concentrated hot molasses ; the solid mass is formed into blocks or bales suitable for transport and is subsequently "broken down" with water and fermented.—J. F. B.

XVIII.—FERMENTATION INDUSTRIES.

Brewing materials. P. Petit. Brasserie et Malterie, 1917, 7, 129—132.

THE author discusses the use of potato-starch, manioc, chit-malt, and raw barley as malt adjuncts. The first is satisfactory (cp. Koudelka, this J., 1917, 399) but expensive. Manioc was employed in several French breweries about 12 or 15 years ago, until a very heavy import duty was placed upon it because it was stated to be cyanogenic. When digested with water it produces about 3 mgrms. of hydrogen cyanide per 100 grms., but this small amount is entirely eliminated in the course of brewing. Manioc requires cooking, like rice or maize, and owing to its slightly alkaline reaction it is advisable to add a small quantity of acid, e.g., 75—100 grms. of phosphoric acid per cwt., before the cooking process. Treated in this way it forms an excellent malt-adjunct. Experience of French brewers with the short-grown or chit-malt advocated by Windisch (see this J., 1917, 1188) has been unsatisfactory. It is difficult to grind properly without a special mill, and does not saccharify completely during the ordinary mashing process ; even when it is first cooked to gelatinise the starch, saccharification and wort-filtration are unsatisfactory. The author considers that raw barley might just as well be used, as all malting expenses are thus eliminated ; the raw grain is ground, preferably in a special mill, and then cooked, or it may simply be steeped as if for malting and cooked without grinding if it is well agitated during cooking. The raw barley may amount to 10—12 % or more of the malt employed.

—J. H. L.

Brewing ; Couch grass as malt-adjunct in — F. Koritschoner. Chem.-Zeit., 1917, 41, 797—798.

IT has been proposed in Germany to utilise the rhizome of couch grass (*Triticum repens*) as brewing adjunct, in view of the present scarcity of malt. The dried rhizome yields about 20 % of extract, derived chiefly from a reserve carbohydrate, tritacin, which forms levulose on hydrolysis. The practical difficulties attending its use in brewing are very great, for it is a very bulky material and requires 10—15 times its weight of water in mashing. Mashed alone, it was found to produce worts dirty red in colour and not altogether pleasant in odour and flavour. These worts developed a peculiar odour during fermentation and the corresponding beers became undrinkable after storage.—J. H. L.

Worts ; Artificial cooling of — in closed coolers, and the elimination of gluten. L. Heintz. Woch. Brau., 1917, 34, 221—224, 230—235.

H. T. Brown has shown that the nitrogenous substances which separate from solution during the cooling of brewers' wort are formed by the combination of wort-proteins with hop-tannins, and that agitation of the wort during cooling

promotes their separation in a flocculent form (see this J., 1913, 442). The author found that with Continental worts, which are of lower gravity and less heavily hopped than those studied by Brown, agitation does not usually bring about flocculation of the precipitate. He suggests that the tendency to flocculate depends on the amount of tannin-protein compounds present. An important means of promoting flocculation is to maintain in suspension, during the cooling process, the proteins coagulated in the copper. A process of wort cooling is described in which this condition is realised. The hot wort, freed from hops but containing the coagulated proteins, is run into a large closed receptacle to a depth of 3—5 ft. From the cover of this receptacle a number of tubular cooling units, resembling ordinary vertical refrigerators in shape, are suspended, so as to be almost completely immersed in the wort. Cold water is circulated through the coolers and the wort is kept in constant agitation by a rotating paddle or by injection of sterile air. When cooled to the pitching temperature the wort may be allowed to stand for a time to allow the precipitate to subside, or it may be filtered. This process enables the whole of the heat of the wort to be recovered, and can be used to heat the water required for mashing. It also protects the wort against infection.—J. H. L.

Wine ; Plastering of grapes and the increase of acidity and sulphates in the — A. Borntraeger. Giorn. Vini-colo Ital., 1917, 43, 412—414. Bull. Agric. Intell., 1917, 8, 1138—1149.

IT is well known that addition of calcium sulphate to grapes at the time they are put in the vat increases the acidity of the wine produced, and the reaction which takes place has been represented by Chancel as follows :— $2C_2H_5KO_6 + CaSO_4 = C_2H_5CaO_6 + C_2H_6O_6 + K_2SO_4$. The author made comparative experiments in three successive years, with white "Catalanesca" grapes from Vesuvius, with and without addition of pure calcium sulphate. After vatting and filtering, the sulphates, expressed as potassium sulphate, and the total acidity, expressed as free tartaric acid, were determined in the wines. In all cases the "plastering" was found to have increased the acidity, but not to the extent calculated from the amount of sulphate present, according to the above equation. One reason for this discrepancy is that the sulphate in the wines consisted in part of unaltered calcium sulphate, and other contributory causes are suggested.—J. H. L.

Wine-making experiments with sulphur dioxide. C. Mensio. Staz. Sperim. Agrar. Ital., 1917, 50, 300—314. Bull. Agric. Intell., 1917, 8, 1140—1141.

COMPARATIVE experiments were made on the use of metabisulphite and certain other recognised preparations of sulphurous acid which contain also phosphoric acid and ammonia, viz., Ottavi mixture, Hubert's "sulphophosphate," and Jacquemin's "biosulphite" (cp. Dalmasso and Sutto, this J., 1916, 134). Black grapes in fairly bad condition and with abundant fungoid growth were employed. The wines made with use of sulphur compounds were more brilliant and possessed an intensity of colour about 30—40 % greater than in the case of the control. This is attributed to the influence of the sulphurous rather than the phosphoric acid, for the results with metabisulphite were slightly better than with the other preparations. About 80 % of the added sulphur remained in the wine, the greater part in combination with acetaldehyde. No trace of ammonium salts was found in any of the wines, and the glycerol-content was in all cases low, about 6.8 grms. per 100 grms. of alcohol. The

total acidity and the content of organic acids in wines made with use of sulphur preparations were higher than in the control, but the volatile acidity was lower. The results indicate that the use of sulphur dioxide in any form is advantageous in wine-making, and that metabisulphite gives somewhat better results than the other preparations used.—J. H. L.

Wine-making; Substitution of calcium sulphite for potassium metabisulphite in —. F. A. Sannino. *La Revista Viticult.*, 1917, 23, 330—331. *Bull. Agric. Intell.*, 1917, 8, 1142.

Owing to the present scarcity of potassium salts the author studied the suitability of various substitutes for potassium metabisulphite, and obtained good results with gaseous sulphur dioxide, and with solutions of sulphur dioxide in water or must. Pure calcium sulphite (free from carbonate and containing 40% SO_2) also proved satisfactory, but it was found necessary to use about 50% more of it than of metabisulphite.—J. H. L.

Alcohol; Determination of —. C. J. Haines and J. W. Marden. *J. Ind. Eng. Chem.*, 1917, 9, 1126—1127.

ALCOHOL can be "salted out" from solutions containing not less than 1 to 2% thereof, by the addition of potassium fluoride. Ten c.c. of the liquid at 15.6° C. (or 5 c.c. diluted to 10 c.c. if the alcoholic strength exceeds 50%), is treated in a centrifugal tube (graduated in 0.01 c.c.) with potassium fluoride until the contents of the tube measure about 13 c.c. A small crystal of malachite green is added to colour the separated alcoholic layer, and the tube closed, shaken vigorously for 2 to 3 mins., allowed to cool, and centrifuged, and the volume of alcohol read, a correction of 0.001 c.c. being made for each 1° C. by which the temperature of the room differs from 15.6° C. To allow for incomplete precipitation and traces of alcohol adhering to the sides of the tube, an addition of 0.15 c.c. must be made to the reading. The method is applicable to beer, cider, spirits, tinctures, etc., and gives results agreeing within $\pm 0.4\%$ of those obtained by determining the sp. gr. of the distillate. In the case of tincture of iodine the presence of the iodine has little effect upon the volume of separated alcohol.—C. A. M.

Hops; Dried "spent" —. J. L. Baker and H. F. E. Hulton. *J. Inst. Brew.*, 1917, 23, 455—457.

For breweries equipped with grains-drying plant it is at the present time a profitable method of disposing of spent hops to dry them, and then grind them finely so that they can be sold for incorporation in cattle foods. The average composition of the dried and ground material is as follows:—Moisture, 4.8%; ash, 7.4%; ether extract (chiefly resins, with traces of fat), 9.0%; proteins ($\text{N} \times 6.25$), 21.9%; crude fibre, 21.6%; pentosans, 13.0%; assimilable carbohydrates, 35.3%. Calories per pound, 1062. Instances of the spontaneous heating and even firing of consignments of the material have occurred. This heating was not due to packing the hops whilst still warm, but was probably in some way connected with spontaneous oxidation of the hop resins, for the heated material acquired an odour like that of linseed oil and the iodine-value of the resins fell from 118 to 93. A preventive measure, which has proved successful up to the present, is to spread the dried and ground hops over a large surface in a fairly thin layer for 24 hours, before the material is packed into bags. During this exposure to the air the spent hops acquire the oily odour already mentioned, and it is possible that the changes which take place may enhance the feeding value of the material.—J. H. L.

Yeast; Autolysis of — and the influence of its products of proteolysis on the development of yeast and lactic bacteria. P. Vansteenberghe. *Ann. Inst. Pasteur*, 1917, 31, 001—630.

THE value of autolysed yeast water must be attributed to the presence of a mixture of proteolytic products in which peptone plays the principal part, and in which the small amounts of a series of substances, such as leucine, tyrosine, and asparagine, exert, independently of the peptone, a favourable influence on the development of yeast and of lactic bacteria also. The value of malt extract probably also lies in the presence of a series of proteolytic products analogous to those from autolysed yeast. (See also *J. Chem. Soc.*, Mar., 1918.)—W. G.

Enzymes concerned in the decomposition of dextrose and mannitol by B. coli communis. II. Experiments of short duration with an emulsion of the organisms. E. C. Grey. *Proc. Roy. Soc.*, 1918, [B], 90, 75—92.

AN emulsion of *B. coli communis* in saline solution containing an amount of bacteria which would weigh, when dry, 1 grm., is sufficient to ferment 40 grms. of dextrose completely in 48 hours in the presence of calcium carbonate. The actual amount of any of the products of fermentation, viz., alcohol, carbon dioxide, formic, acetic, lactic, and succinic acids, obtained is dependent on the concentration of salts and the temperature of fermentation. By comparison of the various amounts produced in different experiments, the author draws the conclusion that alcohol, acetic acid, and succinic acid are all formed from a common intermediate substance by the action of the same enzyme. The formation of lactic acid appears to be quite independent of that of the other products of fermentation, and its production is therefore due to a separate enzyme. The addition of peptone to the culture medium containing dextrose leads to the production of a greater proportion of lactic acid, and a lesser proportion of alcohol, acetic acid, and succinic acid. The products of the bacterial decomposition of mannitol closely resemble in amounts those obtained from dextrose, which result is in harmony with the author's view that the fermentation of various carbohydrates and allied substances by bacteria is effected by a single set of enzymes, the action of which is common to all such cases of fermentation. (See also *J. Chem. Soc.*, Mar., 1918.)—H. W. B.

Enzymes concerned in the decomposition of dextrose and mannitol by B. coli communis. III. Various phases in the decomposition of dextrose by an emulsion of the organisms. E. C. Grey. *Proc. Roy. Soc.*, 1918 [B], 90, 92—106.

By examining portions of a fermenting solution containing dextrose and bacteria at the end of 12, 24, 48, and 72 hours respectively, it was found that during the first 12-hour period the number of living bacteria diminishes almost to nothing, whilst during the second period a rapid growth of bacteria sets in, so that at its close the number present greatly exceeds that at the commencement of the experiment. Corresponding with these changes there is a cessation in the production of lactic acid in the first period, the chief products being carbon dioxide, alcohol, acetic and succinic acids, whilst subsequently in the third period, when the number of bacteria is at a maximum, the production of lactic acid is so much accelerated that it forms 70% of the fermented sugar. The period of exalted bacterial growth is associated with the transformation of a large proportion of the dextrose into a complex carbohydrate which only reduces Fehling's solution after hydrolysis. A synthesis of fat was also observed on one

occasion in circumstances which could not be again realised. The extent of the synthesis during one period is quantitatively of the same order as the degradation which ensues in the following period. The author draws the conclusion that the fermentation is brought about, not by the cells as such, but by enzymes in the cells. Different conditions result in variations in the amounts of the products of fermentation due to the varied influence of the altered conditions on the operation of the different enzymes present.

PATENTS.

Alcohol; Removing — from liquors. R. H. Pflugfelder, Chicago, Ill. U.S. Pat. 1,249,480, Dec. 11, 1917. Date of appl., May 29, 1917.

A DEEP rectangular tank is provided with a series of downwardly-sloping brackets, one above another, fixed alternately to one or the other of two opposite walls and extending nearly across the tank. Each bracket supports a set of heating pipes on which rests a shallow tray, so that liquor delivered to the uppermost tray flows over each of the lower ones in turn, in a zig-zag path, to the bottom of the tank.—J. H. L.

Lactic acid; Manufacture of —. S. Saxe, New York. U.S. Pat. 1,249,511, Dec. 11, 1917. Date of appl. Apr. 20, 1917.

AN organism capable of producing lactic acid is grown in an extract of vegetable ivory, which may be prepared, for example, by hydrolysing the material with sulphuric or other acid and neutralising with calcium carbonate. Sufficient calcium carbonate may also be added to neutralise the lactic acid formed, the latter being afterwards liberated by addition of an equivalent quantity of sulphuric acid.—J. H. L.

Manufacture of alcohol from molasses. Eng. Pat. 112,232. See XVII.

Process for the purification of crude alcohols. Eng. Pat. 112,166. See XX.

XIXA.—FOODS.

Milk; Determination of fat and casein in —. Ratio of casein to fat as a criterion of skimming. F. Repiton. Ann. Chim. Anal., 1918, 23, 11—15.

To determine fat in milk, the author evaporates 10 c.c. of the milk with 5 to 10 grms. of sand, transfers the dry powder to a filter-tube, and extracts the fat by percolation with ether; the ethereal extract is then evaporated and the residue of fat dried and weighed. Another portion of the sample is then treated with dilute alcohol slightly acidified with acetic acid and the precipitate formed, consisting of the casein and fat, is collected, washed with very dilute alcohol, dried at 100° C. for 4 hours, and weighed. After deducting the quantity of fat found previously, the resulting weight is multiplied by 0.942 (allowance for ash) to obtain the weight of the casein. In the case of genuine milk the ratio of casein to fat is 0.82; when this ratio reaches or passes unity, skimming is indicated.—W. P. S.

Fat in condensed milk and milk powders; Determination of —. C. H. Biesterfeld and O. L. Evenson. J. Ind. Eng. Chem., 1917, 9, 1111—1114.

HARDING and Parkin (J. Ind. Eng. Chem., 1913, 5, 131) found that the Röse-Gottlieb method of extracting fat (Landw. Vers. Stat., 1892, 40, 1) did not remove the whole of the fat from evaporated milk, and obtained higher results by a method in which the protein is dissolved in acetic acid and the fat in a mixture of alcohol and carbon tetrachloride prior to extraction with petroleum spirit. The authors' experiments, however, show that these higher results must be attributed to the action of the solvents on the rubber stoppers, and that the average error in the Röse-Gottlieb process when applied to condensed milk does not exceed about 0.04%. The method may also give low results with milk powder or cream, but this error may be corrected by extracting the fat in the presence of acetic acid. From 4 to 4.5 grms. of evaporated milk, or 7 to 7.5 grms. of sweetened condensed milk, is diluted to 9 c.c., and treated first with 1.5 c.c. of strong ammonia solution and then with 15 c.c. of 95% alcohol, and the mixture vigorously shaken for 2 mins. with 50 c.c. of a mixture of 400 c.c. of petroleum spirit, 200 c.c. of ether, and 20 c.c. of 95% alcohol, in a large modified Röhrig tube with side tubulure. After standing for 10 mins. the ethereal layer is drawn off, filtered, and evaporated in a weighed flask. The residual liquid in the tube is treated with 3 c.c. of glacial acetic acid, and the tube immersed to the depth of the liquid in water which is heated from about 60° to 80° C. in about 10 mins. After cooling the tube in running water, 50 c.c. of a mixture of 350 c.c. of petroleum spirit, 280 c.c. of ether, and 63 c.c. of 95% alcohol is introduced, and the tube again shaken for 2 mins. and allowed to stand. The ethereal layer is drawn off and filtered into the same flask as before, and the extraction repeated with an additional 50 c.c. of the same mixture. The united residues of fat recovered from the extracts are dried at 100° C. until constant in weight.

—C. A. M.

Mares' milk; Analysis of —. A. Hildebrandt. Milchwirtsch. Zentr., 1917, 46, 273—278, 289—293, 305—310, 317—319.

THE milk from three mares was examined at intervals during the period April 4 to June 22, 1916; twenty-one analyses were made. The following are the minimum and maximum results obtained: Sp. gr., 1.0296—1.0390; total solids, 8.84—12.03; fat, 0.10—3.35; non-fatty solids, 8.03—9.84; ash, 0.32—0.74; nitrogen, 0.31—0.49; lactose, 4.32—7.56%. Generally, the milks did not give a peroxydase reaction, but in one or two cases a feeble reaction was obtained.—W. P. S.

Pepsin; Rennetic properties of —. H. T. Graber. J. Ind. Eng. Chem., 1917, 9, 1125—1126.

EXPERIMENTS have been made to ascertain the suitability of pepsin from the hog's stomach as a substitute for calf rennet in the manufacture of cheese. Sweet unpasteurised milk which was rapidly curdled by the rennet was only occasionally curdled by the dilute pepsin solution, but by increasing the acidity of the fresh milk to 0.185% (as lactic acid) by the addition of lactic acid, coagulation readily took place. This difference in behaviour points to the rennetic activity being due to a different substance in the two preparations. (See also J. Chem. Soc., Mar., 1918.)

—C. A. M.

Bones; Preparation of edible fat and meat-extract substitute from —. A. Kraus. Preuss. Verband beamt. Nahrungsmittel Chem., July, 1917. Chem.-Zeit., 1917, 41, 835—836.

FRESH bones when heated with water or steam

in an autoclave under 4—6 atmos. pressure yield a considerable quantity of fat which, after washing and clarification, is suitable for human consumption. The average yield of fat is about 15%, and bones from joints which have been boiled in the household will, generally, yield over 8% of fat. The aqueous extract from the bones contains much gelatinous substance and, with the addition of salt and spices, forms an edible product. Old or decomposed bones yield a fat which may be used for technical purposes, whilst the aqueous extract is useful as a manure.—W. P. S.

Cottonseed meal injury; Iron as an antidote to—W. A. Withers and F. E. Carruth. *J. Biol. Chem.*, 1917, 32, 245—257.

THE injurious effects of cottonseed meal may be lessened or prevented by the addition of iron salts to the feed. It is suggested that the iron salts combine with, or facilitate, the oxidation of the harmful substances in the meal.—W. P. S.

Soya bean as food; Use of—T. B. Osborne and L. B. Mendel. *J. Biol. Chem.*, 1917, 32, 369—387.

SOYA bean meal when cooked with water to make it palatable is capable of promoting the growth of young white rats and of maintaining the life of the adult animals. It contains, therefore, both the "water-soluble" and the "fat-soluble" accessory substances, but it is deficient in mineral salts. This latter deficiency may be rectified by the addition to the diet of an artificial mixture of salts.—H. W. B.

Seed proteins; Values of some—for maintenance. *Biological analysis of pellagra-producing diets.* III. E. V. McCollum and N. Simmonds. *J. Biol. Chem.*, 1917, 32, 347—368.

DATA are given which show the minimum amounts of protein which must be taken by rats in order to maintain health and body-weight when the protein is derived from the seeds of wheat, maize, oats, rice (polished), millet, flax, beans, or peas, or, for comparison, from lucerne leaves. Oats are distinctly more efficient for maintenance purposes than either wheat or maize, whilst rice and flax seed are less satisfactory. Millet seed approaches oats in dietetic value in this respect. The protein of lucerne leaves has no advantage regarding maintenance over that obtained from any of the above seeds. All these deductions are based on the supposition that all other accessory dietary factors are present or administered in adequate proportions.—H. W. B.

Yeast-vitamine fraction; Value of the—as a supplement to a rice diet. A. D. Emmett and L. H. McKim. *J. Biol. Chem.*, 1917, 32, 409—419.

THE authors describe the preparation of a vitamine extract which rapidly cures polyneuritis in pigeons. The vitamins in an autolysed yeast filtrate are adsorbed by Lloyd's reagent (a special form of fullers' earth) or by ordinary fullers' earth ground to a definite fineness. Infusorial earth or other commercial kieselguhrs do not adsorb the yeast vitamine. After polyneuritic pigeons have been cured by the vitamine preparation, further attacks of polyneuritis are prevented if doses of fullers' earth containing adsorbed vitamine are administered with the polished rice diet, but the pigeons do not attain their former weights and only a certain amount of growth is observed. If, however, brown rice (unpolished), barley, maize, or similar cereal is fed instead of the polished rice, the pigeons recover or surpass their former healthy condition, and recovery is greatly assisted if the

vitamine preparation is also included in the diet. It appears, therefore, that the outer layers of the rice grain contain two vitamins, one of which cures or prevents polyneuritis and the other produces growth, and of these two, the fullers' earth yeast vitamine preparation contains chiefly the curative fraction. Hence to ensure complete recovery from polyneuritis not only should the adsorbed vitamine be given, but the diet should include foods containing vitamins.—H. W. B.

Orange and lemon peels and pips. F. Mach and P. Lederle. *Chem.-Zeit.*, 1917, 41, 830.

THE composition of these substances was found to be as follows:—

	Water.	Crude protein.	Crude fat.	Nitrogen-free extractives.	Crude fibre.	Ash.

Methods for the production of pure coconut oil. Parker and Brill. See XII.

A precipitant for sugars, starches, gums, proteins, and organic acids. Schulte. See XVII.

Dried "spent" hops. Baker and Hulton. See XVIII.

PATENTS.

Nuts or seeds; Utilisation of certain—in the manufacture of artificial butter or the like. De Bruyn, Ltd., and J. de Bruyn, London, Eng. Pat. 112,164, Dec. 27, 1916. (Appl. No. 18,500 of 1916.)

COCONUT or copra, the kernels of the babassu nut (*Attalea funifera*), or of cohune nuts or of other species of *Attalea*, and, in general, of any species of palm, except *Elæis guineensis*, or the meals or cakes made from these kernels, are used in the manufacture of artificial butter. The washed and cleaned material is finely divided, and agitated with a solution of common salt or of an alkaline salt or salts with similar solvent properties, at a suitable temperature (130°—140° F.), whereby solution and emulsification of part of the material are effected. The aqueous emulsion is separated from the undissolved residue and concentrated *in vacuo*, or it may be treated with acid, and the resulting precipitate redissolved and emulsified in alkaline solution. The original solution or emulsion or that made from the concentrated products is inoculated at a suitable temperature with an active culture of lactic acid bacteria, an addition of lactose or other sugars being made if desired, and the final ripened product is incorporated with a mixture of edible vegetable or animal oils or fats, and converted into artificial butter.—C. A. M.

Flour; Process of bleaching and maturing—J. N. Alsop, Owensboro, Ky. U.S. Pat. 1,250,072, Dec. 11, 1917. Date of appl., Mar. 15, 1915.

FLOUR is bleached and matured by the action of a mixture of chlorine and air, the air having been previously saturated with steam and subjected to a disruptive electric discharge.—W. F. F.

XIXB.—WATER PURIFICATION; SANITATION

Bacilli of Eberth and paratyphoid B bacilli in water; Search for — F. Diénert, A. Guillard, and A. Leguen. *Comptes rend.*, 1918, **166**, 84—85.

PARIS water is examined daily as follows:—Several litres are filtered through collodion, and the deposit is mixed with 50 c.c. of sterile physiological saline solution which is added to 50 c.c. of peptone water containing sterile bile and coloured with malachite green solution. The mixture is incubated at 37° C. for 1—2 days. A trace of this culture is inoculated successively into 5 tubes of melted agar containing lead acetate, and plates are made in Petri dishes. When the medium has set, a tube full of ordinary agar is poured over each, so as to make the cultures anaërobic. The plates are incubated at 37° C., and the colonies examined. Typhoid and paratyphoid B colonies are brown and surrounded with a pale halo; *B. pyocyaneus* gives similar colonies, while *B. coli* colonies are only slightly brown and without a halo. For confirmatory tests typical colonies are subcultured into peptone-bouillon for indole formation and agglutination; into neutral-red glucose agar; into lactose agar; into milk; and on to an agar slant for staining by Gram's method.—J. H. J.

Activated sludge process; Experiments on sewage purification by the — A. Cronin. *Austral. Pharm. Notes*, Oct. 1, 1917, 18—20.

THE first trial of this process in Australia was made at Sydney in 1916. The plant consisted of three wooden tanks of 500 galls. each, air being supplied through perforated pipes covered with broken stone. Two of the tanks were started by seeding with sludge from contact beds, but this method proved a failure. In the third tank raw sewage was treated in the usual way, three days' aeration being followed by 15 hours' settling. Analyses made after 2, 3, and 4 months' working gave practically constant results, the percentage purification being about 99 in suspended solids, 92 in organic nitrogen, and 84 in oxygen absorption. All the effluents were stable by the methylene blue test, and no smell was given off during treatment. A larger tank of 10,000 galls. was then constructed in concrete, and has been in continuous operation since November, 1916, on the fill and draw principle. The aeration period at starting was 4 days, then 3 days, then 20, 10, 7, 6, and 5 hrs. respectively. At the end of 8 weeks, the accumulated sludge occupied 20—25% of the capacity of the tank. The results were not so good after 5 hours' aeration, and after six months the period was fixed at 6 hours with 2 hours' settling, which gave as good results as a longer period. The percentage purification obtained was: suspended solids 96, organic nitrogen 87.7, and oxygen absorption 86.3. The effluent was odourless, of a faint "peaty colour," and was stable after the first 3 weeks' working. The air used was 4.8 cub. ft. per gall. with a ten hours' aeration period. The sludge contained about 66% of moisture and dried readily on sand. An analysis, calculated to a basis of 10% of moisture, showed that it contained 3.2% of total nitrogen, 2.7% of phosphoric acid, and 0.35% of potash.

—J. H. J.

Copper in sewage at the New Haven sewage experiment station. F. W. Mohlman. *J. Ind. Eng. Chem.*, 1917, **9**, 1093—1096.

THE sewage after receiving the residual acid waste from a large munitions factory where the scale is removed from brass shells, after annealing, contained from 5.6 to 8.8 parts per million of

copper. The effect of this copper was to reduce the number of bacteria from 990,000 to 3000 per 20 c.c.—C. A. M.

PATENTS.

Water; Method of sterilising — P. C. Rushen. London. From Quarzlampen Ges. m. b. H. Hanau, Germany. Eng. Pat. 112,149, Dec. 6, 1916. (Appl. No. 17,538 of 1916.)

WATER containing humic substances, etc., is sterilised by means of chemically active rays or light radiations (e.g., from a mercury quartz lamp), the action of which is assisted by adding to the water a very dilute solution of a photo-dynamically active substance, such as eosin.

—C. A. M.

Distilling apparatus [for sea-water]. J. Andrews. Kirkintilloch. Eng. Pat. 112,223, Apr. 27, 1917. (Appl. No. 5972 of 1917.)

A STEAM-HEATED still, a feed-water heater, a tubular combined water-heater and condenser, and a receiver, are arranged so that all or a portion of the distillate may be sent direct to the hot well, to a hot water tank for domestic or other purposes, or through a combined cooler and filter to a cold drinking water tank.—W. H. C.

Sterilising animal and vegetable products; Process of — H. Bart, Landau, Germany. U.S. Pat. 1,250,079, Dec. 11, 1917. Date of appl., June 29, 1917.

ANIMAL and vegetable substances are treated with nitrogen protoxide at pressures between 5 and 25 atmospheres and at a temperature below normal. The process is applicable to vaccines and similar preparations. The substance to be treated may be first rendered completely or partially germ-free, and then preserved by the process. The process may be carried out also above 25 atmospheres' pressure.—J. H. J.

Water; Process of softening — H. Heller, Cologne, Germany. U.S. Pat. 1,247,833, Nov. 27, 1917. Date of appl., Mar. 27, 1916.

SEE Eng. Pat. 103,698 of 1916; this J., 1917, 401.

Permutites; Process for regenerating — W. C. Foster, Rutherford, N.J., Assignor to Staten Island Chemical Corporation, New York. U.S. Pat. 1,249,368, Dec. 11, 1917. Date of appl., Aug. 19, 1915.

SEE Eng. Pat. 101,207 of 1916; this J., 1917, 977.

Sterilising and preserving animal and vegetable products; Process for — and for preparing inoculating substances or vaccines. H. Bart, Bad Dürkheim, Germany. Eng. Pat. 112,498, Jan. 9, 1917. (Appl. No. 404 of 1917.)

SEE U.S. Pat. 1,250,079 of 1917; preceding.

Sterilising liquids contained in hermetically-closed vessels; Apparatus for — L. Giommi, Milan, Italy. U.S. Pat. 1,249,740, Dec. 11, 1917. Date of appl., Apr. 9, 1913. Renewed Dec. 22, 1916.

SEE Eng. Pats. 9912 of 1912 and 30,048 of 1913; this J., 1913, 622; 1915, 197.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Asparagus sprengeri; Oil from [flowers of] — F. Elze. *Chem.-Zeit.*, 1917, **41**, 842.

THE flowers of *Asparagus sprengeri*, a variety of asparagus usually grown for decorative purposes, when extracted with a solvent yield an oil having

a strong aldehydic odour; this oil yields a semi-carbazone. If the oil is obtained by subjecting the flowers to steam-distillation, the odour is less intense and the steam has evidently a decomposing action on the oil.—W. P. S.

Cyanamide; Preparation of —. A. E. Osterberg and E. C. Kendall. J. Biol. Chem., 1917, 32, 297—298. (See J. Chem. Soc., Mar., 1918.)

AN aqueous suspension of calcium cyanamide is decomposed by carbon dioxide at a temperature below 40° C. The calcium carbonate is filtered off and the cyanamide recovered from the filtrate by concentrating *in vacuo* and subsequently extracting with ether. The yield of pure crystallised cyanamide is about 92% of the theoretical, reckoned on the amount of calcium salt employed.

—H. W. B.

Bark of the Hymenodactylon erectum: Constituents of the —. C. S. Gibson and J. L. Simonsen. J. Proc. Asiatic Soc. Bengal, 1916, 12, 161. (Reprint.)

THE extract of this bark when subcutaneously injected into two frogs gave no indication of any physiological action. The glucoside, aesculin, and its product of hydrolysis, scopoletin, were isolated from the bark.—W. G.

Sera; Influence of phenol and of cresylic acid [cresol] on the concentration of antitoxin — by the Banzhaf (1913) process. A. Homer. Biochem. J., 1917, 11, 277—282. (See also this J., 1917, 734.)

THE Banzhaf process may be improved by treating the original diluted plasma with 2% of sodium chloride and 0.3—0.35% of cresol before heating with ammonium sulphate. Between these limits of concentration cresol was found to give better results than phenol. The method of operating was as follows:—Oxalated plasma, diluted with one-fifth of its volume of water, was treated with 2% of sodium chloride and 0.3—0.35% of cresol, followed by sufficient saturated ammonium sulphate solution to bring the concentration of this salt to 30% of saturation. The liquid was heated gradually just to 60° C. and then cooled to 45° C. and filtered. The precipitate ("first fraction precipitate" consisting of protein practically free from anti-toxin) was washed with ammonium sulphate solution 30% saturated, and the mixed filtrate and washings treated with more ammonium sulphate to raise the concentration of this salt to 50% of saturation. The ensuing "second fraction precipitate," containing practically all the antitoxin, was filtered off, pressed, and dialysed as usual. Operating in this way on 50 litres of oxalated antitetanic serum, a final product was obtained occupying only 6.5 litres, containing 18.6% of protein (compared with 8.26% in the original plasma) and possessing a potency 8 times that of the original plasma, whilst Banzhaf's process only produces a 4- or 5-fold increase in potency and removes much less protein. The product was moreover clear and limpid. On dilution with saline it showed no trace of the presence of a colloidal suspension of euglobulin or of protein denatured by heat. It could be readily filtered through filter-candles and the filtered product did not become cloudy on standing. No undue loss of antitoxin occurs in this modified process provided the addition of 2% of salt is made and the mixture is neither heated beyond 60° C. nor allowed to remain at this temperature for more than 2—3 mins.—J. H. L.

Nucleic acids; Preparation of plant —. G. Clarke and S. B. Schryver. Biochem. J., 1917, 11, 319—324.

KNOWN methods of preparing nucleic acid from plant materials yield products containing protein,

which has afterwards to be removed by peptic digestion. To avoid this the authors devised a method in which the protein is first rendered unextractable, by heating with alcohol. The method was applied to yeast as follows:—Freshly pressed yeast was allowed to stand for 24 hours with a large excess of 95% alcohol, and afterwards dried in the air. The air-dried material was boiled for 2 hours with 95% alcohol, filtered, pressed, dried in a current of air at 37° C., and ground to a fine powder. One kilo. of the powder was extracted with 10 litres of 10% sodium chloride solution for 4—5 days, with frequent stirring and intermittent heating to 60°—80° C. The extract, filtered first through muslin and then through paper, was treated with 90 c.c. of hydrochloric acid (1:1) and vigorously stirred. After standing for 2 hours the liquid was siphoned off from the deposited cake of crude nucleic acid, and the latter was left overnight in 95% alcohol and then washed with absolute alcohol and ether. The yield was 1.4—1.6% of the dried yeast and the product did not give the biuret reaction. It was purified by dissolving 20 grms. in 500 c.c. of 10% sodium acetate solution in a water-bath, filtering, and adding 100 c.c. of alcohol and excess of hydrochloric acid. The precipitate, washed with 50% alcohol, 95% alcohol, and ether and dried *in vacuo*, formed a pure white powder. In applying this method of preparation to materials containing starch, it is best to saccharify the latter. For instance, wheat embryos were boiled with alcohol, dried in the air, heated with water to gelatinise the starch, saccharified by means of taka-diaxase, and then extracted with 10% salt solution.—J. H. L.

Formaldehyde and hexamethylenetetramine; Iodine as a microchemical reagent for —. C. van Zijp. Pharm. Weekblad, 1918, 55, 45—47.

IODINE gives with hexamethylenetetramine a compound of characteristic crystalline form which is not insoluble in alcohol as stated by Schmidt. The hexamethylenetetramine dissolved in a small drop of water is treated with a drop of iodine-potassium iodide solution (1:1:100), and protected from evaporation of the iodine (resulting in the disappearance of the crystals) by a cover-glass. 0.3 µgrm. of hexamethylenetetramine may be detected in this manner; formaldehyde is detected after being converted into hexamethylenetetramine by means of ammonia solution.—F. W. A.

PATENTS.

Smelling salts and solidified inhalants; Solidified —. C. A. Cofman-Nicoresti, London. Eng. Pat. 112,061, Jan. 29, 1917. (Appl. No. 1415 of 1917.)

ALCOHOL, liquid paraffin, or an essential or volatile oil is solidified by the addition of 5—10% of sodium stearate, and the mixture, just before it sets, is caused to absorb formaldehyde, ammonia, chlorine, or any other gas to produce a solidified inhalant or disinfectant.—J. F. B.

Alcohols; Process for the purification of crude —. W. J. Crawford, Llanelly. Eng. Pat. 112,166, Dec. 28, 1916. (Appl. No. 18,559 of 1916.)

CRUDE alcohols are treated with a concentrated

solution of sodium hypochlorite (sp. gr. 1.20), e.g., 1 part of crude wood naphtha with 2 of the hypochlorite or 2 parts of ethyl alcohol with 1 of hypochlorite, the quantity being such that no free chlorine is produced on distillation. The mixture is distilled and the chloro-compounds are separated from the distillate after dilution with water. If necessary, the treatment is repeated and the alcohol is finally purified by distillation with a dilute solution of alkali carbonate or calcium hydroxide.—J. F. B.

PATENTS.

Antigens for tubercle bacilli; Preparation of —. K. Momose, Osaka-Fu, Japan. Eng. Pat. 103,298, Jan. 6, 1917. (Appl. No. 283 of 1917.) Under Int. Conv., Jan. 7, 1916.

BOUILLON cultures of tubercle bacilli are washed with salt solution and water, pressed between sterilised filter-paper, and shaken and digested for about 48 hours in the dark, at 17° to 22° C., with 10% soda lye. They are then washed successively with salt solution and water, and the sediment repeatedly shaken, for about 2 hours each time, with chloroform to extract the waxy substance; the chloroform is separated by centrifuging. The residual stroma is dried at about 60° C., and made into an emulsion with salt solution and some carbolic acid.—C. A. M.

Acridine series; Manufacture of therapeutically valuable compounds of the —. O. Inray, London. From Soc. of Chem. Ind. in Basle, Switzerland. Eng. Pat. 112,809, Jan. 23, 1917. (Appl. No. 1166 of 1917.)

SEE U.S. Pats. 1,127,624 and 1,128,926 of 1917; this J., 1917, 867, 905. In addition to cadmium and silver salts, other heavy metal compounds, except zinc chloride, may be used in the preparation of the products.

Alkaloidal compound. J. U. Lloyd, Cincinnati, Ohio. U.S. Pat. 1,250,331, Dec. 18, 1917. Date of appl., July 6, 1915.

A COMPOUND consisting of an alkaloidal substance with an insoluble compound containing magnesium, e.g., hydrated magnesium silicate, is claimed.

—F. W. A.

Desoxycholic acid: Process of producing addition compounds of —. H. Wieland, Munich, Germany. U.S. Pat. 1,252,212, Jan. 1, 1918. Date of appl., May 16, 1917.

ADDITION compounds of desoxycholic acid with aromatic compounds are produced by dissolving one component in a hot solvent and adding the other component. The production of phenolcholeic acid (m. pt. about 165° C.), by the addition of desoxycholic acid to liquefied phenol and removal of the excess phenol by means of a solvent, is specially claimed.—F. W. A.

Manufacture of lactic acid. U.S. Pat. 1,249,511. See XVIII.

Process of sterilising animal and vegetable products [e.g., vaccines]. U.S. Pat. 1,250,079. See XIXb.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photo-chemical processes; True —. F. Weigert, Z. Elektrochem., 1917, 23, 357—368. (See also J. Chem. Soc., March, 1918.)

A THEORETICAL paper, in which after real and ideal photochemical processes have been differentiated

and a general survey has been made of a number of real processes, the author propounds a theory of the mechanism involved in the reactions. The author includes in the general discussion the processes operative in photo-electric actions, fluorescence, luminescence, and Röntgen-ray effects.—J. F. S.

XXIII.—ANALYSIS.

Collodion membranes; Preparation of uniform — for dialysis. C. J. Farmer. J. Biol. Chem., 1917, 32, 447—453. (See also J. Chem. Soc., March, 1918.)

THE membrane is prepared by filling a glass tube with collodion solution (3 grms. of dried gun cotton to 50 c.c. of a mixture of equal parts of absolute alcohol and ether), inverting, and allowing to drain for one minute. The tube is then dried for one minute in a current of air and afterwards filled with cold water. After a few minutes, the thin membrane can be removed from the walls of the glass tube with the aid of a pair of forceps. The permeability of the membrane may be changed by varying the period of drying. Convenient apparatus for performing these operations is described in detail.—H. W. B.

Fluorine; Method for the determination of — with special application to the analysis of phosphates. C. R. Wagner and W. H. Ross. J. Ind. Eng. Chem., 1917, 9, 1116—1123.

A WEIGHED quantity of the dried material containing from 0.001 to 0.1 grm. of fluorine is mixed with 0.1 to 1 grm. of silica and 5 grms. of anhydrous copper sulphate in a 250 c.c. flask, one outlet of which is connected with a cylinder of compressed carbon dioxide or nitrogen fitted with a reducing valve, whilst the other outlet is connected with two traps containing strong sulphuric acid. Following these are a Schmitz tube containing a 10% solution of silver sulphate in 98.5% sulphuric acid, a Bowen tube containing a saturated solution of chromium trioxide in 98.5% sulphuric acid, a straight piece of tubing packed with glass wool, and, finally, a large test-tube containing about 50 c.c. of water. After the introduction of 100 c.c. of 98.5% sulphuric acid into the generating flask, a slow current of the inert gas, which passes through two wash-bottles containing sulphuric acid before entering the flask, is passed through the apparatus at the rate of 2 to 3 bubbles per minute, and this is continued throughout the determination. The flask is then gently heated, the final traces of silicon fluoride being expelled by means of the current of gas. Sulphur dioxide and trioxide and any hydrochloric or nitric acid are retained by the reagents in the Schmitz and Bowen tubes, so that the solution of hydrofluosilicic acid in the final tube is quite free from other acid substances. It is made up to 200—250 c.c., gently boiled to expel dissolved gases, cooled slightly, and titrated with *N*/10 sodium hydroxide solution, with phenolphthalein as indicator. Organic matter is removed by a preliminary ignition of the sample. The method is specially applicable to the determination of fluorine in phosphates, and was devised in connection with the so-called volatilisation method of recovering phosphoric acid from mineral phosphates (see this J., 1916, 1154; 1917, 134).—C. A. M.

Sulphuric acid and barium; Gravimetric determination of — as barium sulphate. Z. Karaglanow. Z. anal. Chem., 1917, 56, 417—439. (See also J. Chem. Soc., 1918, ii., 47.)

In dilute solution, the precipitation of sulphuric

acid as barium sulphate depends on the concentration of the acid and on the quantity of barium chloride added; the quantity of barium sulphate formed decreases with an increase of barium chloride. This decrease is not due to solubility since barium sulphate is practically insoluble in the presence of barium chloride. When the precipitation is made from a solution containing a relatively large amount of hydrochloric acid or nitric acid, the results are too high. The presence of potassium chloride makes the results low, whilst with potassium nitrate they are too high, the extent of the influence of these two salts depending on the concentration of the solution. Potassium sulphate also causes low results but when hydrochloric acid is present in addition the results are too high. In the case of a solution containing both potassium chloride and potassium sulphate, the quantity of barium sulphate recovered is too low whether or not hydrochloric acid is present. If, however, the solution is very dilute the conversion of potassium sulphate into barium sulphate is quantitative even in the presence of nitric acid. The presence of sodium, ammonium, zinc, and magnesium chlorides does not affect the results; ferric chloride causes the figures for barium sulphate to be very low (about 3%), but in very dilute solutions containing hydrochloric acid the influence of iron salts is very small. Aluminium chloride in the presence of hydrochloric acid does not interfere, but chromium chloride causes the results for barium sulphate to be much too low.

—W. P. S.

Strontium chloride and strontium bromide; Transition temperatures of — as fixed points in thermometry. T. W. Richards and V. Yngve. J. Amer. Chem. Soc., 1918, 40, 89—95.

THE temperature at which the hexahydrate of strontium chloride is converted into the dihydrate is 61.341° on the international hydrogen scale. The corresponding change in strontium bromide takes place at about 88.62°. These temperatures may be used as fixed points for thermometric purposes. It has been found that the recrystallisation of strontium chloride in the form of the hexahydrate rapidly removes any barium present. Calcium is not nearly so rapidly eliminated, but if the salt is recrystallised to give the dihydrate, the calcium is quickly removed. By combining the two processes, strontium may be freed from both calcium and barium. The separation of small quantities of calcium from strontium may also be effected by crystallising the nitrates at a sufficiently high temperature to produce the anhydrous salt. (See also J. Chem. Soc., March, 1918.)

—H. M. D.

Sodium and potassium; Estimation of —. F. H. McCrudden and C. S. Sargent. J. Biol. Chem., 1918, 33, 235—241.

SODIUM and potassium are separated from other compounds as the combined chlorides and the amount of each is calculated from the chlorine content of a known weight of the mixture. The authors show that when the McLean-Van Slyke method (this J., 1915, 608) is employed for estimating the chlorine, the probable error in the estimation of the sodium increases as the ratio of sodium to potassium decreases and amounts usually to about 1%. (See also J. Chem. Soc. March, 1918.)—H. W. B.

Phosphoric acid; Estimation of — as magnesium pyrophosphate. D. Balareff. Z. anorg. Chem., 1917, 101, 229—234.

THE different methods of precipitating magnesium ammonium phosphate, namely, the older cold precipitation method of Neubauer and the hot methods of Schmitz, Jorgensen, and Järvinen have been compared, and it is found that, provided

precipitation takes place from pure aqueous solution, the results obtained are equally satisfactory, whichever method be used. In the presence of alkali cations, K⁺ or Na⁺, however, high results are obtained, the effect being smaller at higher temperatures. If the concentration of alkali is great, even a second precipitation does not completely purify the precipitate. Sulphate ions have the same effect as alkali ions. Slow precipitation leads to low results, and the author concludes that rapid precipitation at a high temperature is best for accurate work. It appears probable from the author's experiments that the high results obtained when precipitation takes place in presence of alkali salts or of sulphates are not due to adsorption but to the formation of mixed alkali-magnesium phosphates.—E. I.—GENERAL; PLANT; MACHINERY.**PATENTS.**

Oil extracting, cooling and like apparatus for use with compressed air. H. Smethurst, Hollinwood. Eng. Pat. 112,362, Apr. 23, 1917. (Appl. No. 5664 of 1917.)

The compressed air enters through the opening, O, passes through the wood-wool filter, N, and after being partly purified it passes up the corrugated tube, B, contained in the casing, A, and escapes at E. Cooling water is passed through the casing, A, and the compressed air, directed into the corrugations of the tube by the flanges on the central rod, D, is cooled and deposits the oil, which flows down into the bottom chamber from which it is from time to time discharged through the pipe, K.

—W. H. C.

Separation and recovery of liquids of different densities, and the separation of light solid particles from a heavy liquid; Process and means for the —. E. Sepulchre, Woluwe-St. Pierre, Belgium. Eng. Pat. 103,670, Jan. 24, 1917. (Appl. No. 1192 of 1917.) Under Int. Conv., Oct. 20, 1915.

THE two immiscible liquids to be separated, e.g., petroleum and water, are contained in the tank, 1, shown in plan, and the heavier portion is withdrawn through the sluice, 3, to the discharge channel, 4, 5. The lighter mixture passes into the channel, 6, which diverges horizontally and

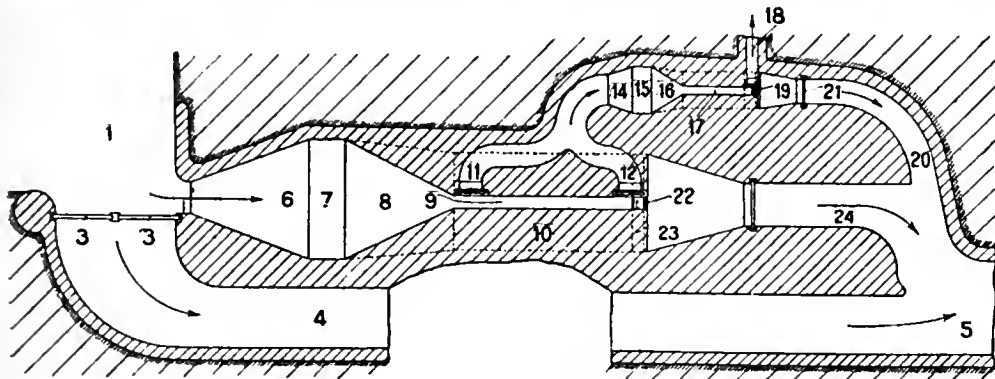

has its floor sloping upwards towards the flat-topped weir, 7, where the liquids separate by gravity. The lighter liquid flows on through a channel, 8, of decreasing section, and the heavier liquid through the lower part of the channel which deepens and widens to a large channel, 10. The lighter liquid is drawn off from the narrow upper part, 9, of the channel through the passages, 11, 12, to a second similar separating device, 14, 15, 16, 17. The lighter portion is finally withdrawn through the channel, 18, and the heavier portion passes under sluices, 19 and 21, to the channels, 20 and 5. The heavier liquid from the channel, 10, passes under a vertical plate, 22, having a lip, 23, at the bottom, curved backwards, so that a flat sheet of the liquid is formed and the lighter portions are separated and diverted upwards. In a modification, the mixture is delivered into a vertical column, having a flat horizontal outlet at the bottom, into a horizontal chamber having a triangular section which gradually increases in size. The lighter liquid is separated in the upper narrow part of the chamber, and rises into a vertical discharge column. The heavier liquid passes along the floor of the chamber, and over a lip projecting upwards just below the column for the lighter liquid, so that it is spread out into a shallow stream and any lighter particles separated upwards. The heavier liquid then passes on to another discharge column of less height than that for the lighter liquid.—W. F. F.

Cooling and drying compressed materials and substances, seeds and the like; Apparatus for — and for removing dust therefrom. W. Marshall, Kingston-upon-Hull. Eng. Pat. 112,512, Jan. 17, 1917. (Appl. No. 827 of 1917.)

In an apparatus for cooling, drying, and eliminating dust from compressed blocks or pieces of material such as cattle food, a hopper provided

with a delivery spout projecting from the side is mounted centrally above the apparatus shown in the figure in sectional half plan, and rotated slowly by bevel gearing so as to deliver the material into a number of sector-shaped cooling and

drying chambers, A. Each chamber is provided with a number of superposed spreaders, each comprising a hollow cone, A¹, with a short central tube, A², projecting upwards nearly to the base of the next cone. Each drying chamber is provided with perforated grids or plates, F and D, the latter forming the walls of radial air passages, B, leading from a central air chamber, C. The inner walls of the chamber, A, are provided with cooling ribs, C², projecting into the chamber, C. Air is supplied from a pump through a central supporting standard to the chamber, C, and passes thence through the passages, B, which are covered at the top, to the chambers, A. The air passes into the annular space enclosed by the outer casing, G, where dust is allowed to settle, and finally escapes through a dust-collecting fabric at the top. The dried material is delivered through hoppers at the base of the chambers, A. In a modification, the cooling chambers are arranged side by side in line, the air being delivered to a common air space at the back and passing into the cooling chambers through the perforated walls.—W. F. F.

Cooling, humidifying and filtering air or the like; Apparatus for —. H. F. Brown, Sheffield. Eng. Pat. 112,653, Jan. 16, 1917. (Appl. No. 769 of 1917.)

IN apparatus of the type in which the air to be treated is passed between wet plates, the plates are arranged radially and vertically in a cylindrical casing. Water is supplied upwards through a central rotating pipe carrying horizontal perforated branches which move over the top of the plates. The horizontal branches are shaped similarly to the horizontal section of the plates, which are preferably curved to an involute form. The perforations are on the lower side of the pipes, which carry horizontal flanges to overlap several of the wet plates, the flange on the following side being wider than that on the leading side. Air is thus prevented from passing upwards over those plates to which water has just been supplied and where there is thus an excess of water. The water drips off the plates on to a conical plate having a filter arranged around its periphery, and thence into the bottom of the casing from which it is supplied again to the sprinkler by a pump. A constant level of water is maintained in the casing by means of a float valve.—W. F. F.

Furnaces; Oil-fired —. R. Halkett, Glasgow. Eng. Pat. 112,700, Mar. 24, 1917. (Appl. No. 4278 of 1917.)

IN an air control device for an oil-fired boiler furnace, a cylindrical casing is fixed to the front of the furnace and provided with openings in its periphery controlled by hinged louvres. Tangential guide-vanes are attached to the inner cylindrical wall of the casing to give the air a rotary motion, and the air passes inwards through two similar concentric sets of guide-vanes to the centre of the cylinder, where it meets the oil spray from a central spray burner. The burner is provided with tangential passages to give the spray a whirling motion, and the delivery is regulated by a needle-valve.—W. F. F.

Baking-furnace [for carbons, etc.]. R. K. Wehner, Assignor to Isbell-Porter Co., Newark, N.J. U.S. Pat. 1,251,309, Dec. 25, 1917. Date of appl., Aug. 26, 1916.

IN a gas-fired furnace of the ring type for baking carbons and the like, a battery of ovens is arranged in two parallel groups. The heating flues in the side walls of the ovens do not communicate with the interior of the ovens. Gas-supply mains extend along the outer sides of the ovens and are connected to a gas burner in each flue, and an air-supply main and exhaust main are arranged

between the groups of ovens and connected to each flue. The flues are arranged with alternate up and down passages connected in series, and passages are provided under the floors of the ovens to connect the down flues of one side wall with the up flues of the next wall. In operation, gas under pressure is admitted to the oven being fired, and air under pressure to the series of connected flues of other ovens previously fired. The combustion products are exhausted through the flues of all the ovens to be fired, and the pre-heated air is supplied by the same means to the oven being fired. The flow of gas, air, and combustion products is thus kept uniform, and a minimum pressure difference is maintained between the flue pressure and the atmosphere so as to minimise leakage of cold air into the heating flues.—W. F. F.

Oxidising gases; Process and apparatus for —. I. Hechenbleikner, Charlotte, N.C., Assignor to Southern Electro Chemical Co., New York. U.S. Pat. 1,249,392, Dec. 11, 1917. Date of appl., Feb. 5, 1914.

A CURRENT of gas or vapour is passed through a chamber and is oxidised by oxygen supplied in a number of fine streams, some of which move in the direction opposite to the current of gas or vapour and others at right angles thereto, so as to produce a swirling motion in the current of gas.—W. H. C.

Calandria for vacuum drying-pans and the like. H. S. Truscott, Makaweli, Hawaii. U.S. Pat. 1,249,557, Dec. 11, 1917. Date of appl., Sep. 5, 1916.

THE upper and lower tube-plates of the calandria have the form of an inverted truncated cone with a peripheral horizontal portion near the casing. The calandria has a large vertical central tube, surrounded by groups of smaller, inclined tubes set at right angles to the inclined portion of the tube-plates, and these are again surrounded by a ring of larger vertical tubes.—W. H. C.

Filter frame or leaf. O. J. Salisbury, Salt Lake City, Utah. U.S. Pat. 1,249,835, Dec. 11, 1917. Date of appl., Mar. 18, 1916. Renewed Aug. 4, 1917.

A FILTER frame is built up of sections of segmental shape, each of which consists of parallel, spaced, perforated plates covered with filter cloth and enclosing the filtrate space between them. The radial edges of the sections are tongued and grooved so that several may be united, substantially in one plane, into a complete circular frame or leaf.—W. H. C.

Steam-heated drying-cylinders; Testing attachment for —. G. H. Barrus, Brookline, Mass., Assignor to International Paper Co. U.S. Pat. 1,249,886, Dec. 11, 1917. Date of appl., Sep. 30, 1915.

THE pipe by which the condensed water from a rotary steam-heated drying cylinder is discharged, is provided with means for stopping the discharge at will, and also with a vent discharging into the air so that the condensed water can be inspected. The discharge pipe can be turned about its axis so as to vary the height of the inlet opening.—W. H. C.

Separation of suspended particles from gases; Process and apparatus for —. H. A. Burns, Assignor to International Precipitation Co., Los Angeles, Cal. U.S. Pat. 1,250,088, Dec. 11, 1917. Date of appl., Apr. 18, 1914.

THE gas is passed through the space between a discharge electrode having a relatively small surface and a liquid receiving electrode having a relatively large surface. A continuous electrical

discharge, maintained from the discharge to the collecting electrode, charges the suspended particles and causes them to move across the path of the stream of gas to the surface of the liquid collecting electrode. The latter flows in a continuous stream and carries away the collected particles.—W. H. C.

Evaporator. D. Cozzolino, Los Angeles, Cal. U.S. Pat. 1,250,094, Dec. 11, 1917. Date of appl. Sep. 20, 1916.

THE liquid to be evaporated is sprayed into the top of a vertical cylinder, and falls through a number of spaced, superposed screens of smaller diameter than the cylinder, the concentrated liquid collecting in the dome-shaped lower end of the cylinder. The cylinder has an upper vapour exit connected with a vacuum pump and is provided with a cooling coil just above the surface of the liquid to break up any foam that is formed.—W. H. C.

Initial temperature, °C.	20	100	150	200	250	300	350	400	500	600	700	750	800

Evaporator. G. C. Westby, Ludwig, Nev., Assignor to Western Process Co. U.S. Pat. 1,250,258, Dec. 18, 1917. Date of appl. Aug. 17, 1915.

A SERIES of layers of slats are arranged in vertical tiers in a framework, with an open space extending vertically through the centre of the layers, in which a pipe coil is arranged. A heating fluid is circulated through the pipe coil and the liquid to be evaporated is distributed from a superposed tank having its bottom perforated above the slats but not above the central space.—W. F. F.

*Liquids; Method of treating—*to remove dissolved salts. H. L. Doherty, New York. U.S. Pat. 1,251,486, Jan. 1, 1918. Date of appl. July 16, 1912. Renewed June 7, 1917.

THE liquid is subjected to comparatively quick heating in steps at temperatures increasing successively, by contact with a gaseous heating medium which has been partly preheated by contact with a previous charge of the liquid. The liquid is withdrawn at each step before any substantial amount of solid has crystallised, and caused to flow in a thin film over surfaces

Initial pressure, mm. mercury	760	1250	2100	2900	3350	3750	4650
Methane %, lower limit	6.00	6.05	—	6.20	6.25	—	6.40

Process of making decolorising agents and the products thereof. U.S. Pat. 1,251,516. See XVII.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Methane and air; Effect of temperature and pressure on the limits of inflammability of mixtures of—. W. Mason and R. V. Wheeler. Chem. Soc. Trans., 1918, 113, 15—57.

MIXTURES of methane and air were saturated with water vapour at 20° C. and ignited by means of an electric spark in a U-tube of transparent quartz, one limb of which was closed and was longer than the other. Since the limits for upward or horizontal propagation of flame are wider than for downward propagation (this J., 1914, 1194), a flame just sufficient to reach the bottom of the shorter limb was carried up into the longer limb, where it could be observed in the space projecting above the furnace which heated the U-tube. The effect of temperature upon the inflammability at pressures lower than atmospheric pressure was thus found to be as follows:—

These results agree closely with those obtained by Taffanel and Floch (this J., 1913, 646, 939, 999). Under the conditions described, combustion without flame takes place to an appreciable extent above 600° C., as is shown by the fact that when a mixture containing 18.7% of methane was left in the tube for 5 seconds at 700° C. before sparking, no ignition occurred, whilst at 750° C. a mixture containing 23.5% of methane became non-inflammable after standing for 1.5 secs. before sparking. This may be attributed to the consumption of oxygen by the methane, and hence the results above 600° C. are not the true values for the upper limits of the auto-propagation of flame in mixtures of unaltered methane and air. For measuring the limits of inflammability at pressures above atmospheric pressure, the mixtures of methane and air were forced through a condensing syringe into a strong vertical glass tube the lower part of which was covered with black paper in which was cut a horizontal slit at a point 15 cm. below the point of ignition. Flame seen to pass this slit was considered to have traversed the tube. The following results were obtained:—

These lower limits agree closely with the results of Terres and Plenz (this J., 1916, 461), but the upper limits are higher than theirs, probably because in their experiments the source of ignition was not strong enough. Mixtures containing more than 11% of methane require a secondary discharge of considerable intensity for their ignition, and the intensity necessary increases rapidly with the rise in the proportion of methane. (See also this J., 1916, 345, 682; 1917, 283, 378, 702, 955.)—C. A. M.

Hydrocarbon gases and vapours; "Spark-lengths" in—. R. Wright. Chem. Soc. Trans., 1918, 113, 79—80.

THE following average results were obtained from three or more measurements, which usually differed by as much as 10%:—

Spark-lengths.

	Hydrogen.	Methane.	Ethane.	Propane.	n-Butane.	n-Pentane.	Isopentane.	Hexane.	Heptane.	Benzene.	Toluene.
Air-gap=30 mm.	80	31	25	20	16	14	10	12	9	13	12
Air-gap=20 mm.	55	22	18	15	13	11	8	10	6	9	9

With the exception of isopentane an increase in the insulating power accompanies a rise in the molecular weight in the series.—C. A. M.

[*Petroleum*] oil prospects of the British Isles. W. H. Dalton. J. Inst. Petroleum Tech., 1917, 4, 37—50.

THE author reviews the known instances of the occurrence of petroleum in the British Isles and shows that oil in small quantity has been found over the whole country and in many of the geological formations from the Old Red Sandstone upwards. He concludes that oil-forming conditions have frequently recurred, but to a very limited extent, and that although conditions favourable to the accumulation of oil, and tectonic structures capable of conserving it from escape, are also of frequent occurrence, the conjunction of the latter essentials with original formation has generally failed. Whether from defect of original formation, of space accessible for accumulation, or of adequate seal from escape, the total result is, from a practical commercial point of view, almost entirely valueless.—T. ST.

Motor fuel; Testing and standardisation of —. E. L. Lomax. J. Inst. Petroleum Tech., 1917, 4, 6—25.

THE author discusses the methods which have been proposed for determining the constituents and character of petroleum spirits, with the object of calling attention to the need for the adoption of British standard tests and specifications for motor fuel. *Specific gravity.* Owing to the varying amounts of the several classes of hydrocarbons which are present in spirits from different sources, the specific gravity is no criterion of the volatility, or, consequently, of the value as a motor fuel, of any given sample, and serves only as the basis for calculating the weight per given volume. It would be desirable, however, to have a generally accepted standard temperature for its determination. *Distillation tests.* Of the two best known methods of carrying out the distillation test, the Redwood method is shorter and less liable to personal error than the Engler method, but tends to mask the presence of low-boiling hydrocarbons, particularly when these are present in small quantities. The author has designed a special form of apparatus, of which a detailed description is given, to obtain the completeness of fractionation of the Engler method with the rate of distillation and ease of manipulation of the Redwood method. The special feature of this apparatus is a 4-pair Young dephlegmator column protected from draughts, and air-lagged, by an enclosing wide glass tube. *Sulphur.* The sulphur-content of petroleum spirits may be determined either by burning the spirit in a current of air and absorbing the products of combustion, or by combustion with oxygen in a calorimetric bomb. Owing, however, to the small weights which can be taken for test in the latter method, the accurate estimation of small percentages of sulphur becomes very difficult. The author gives a brief description of various modifications of the air-combustion method, and describes in detail one in which the petrol is mixed with alcohol and the mixture burnt in a good current of air, the products of combustion being absorbed by a definite quantity of a standard solution of sodium carbonate,

which is afterwards titrated against a standard solution of sulphuric acid, methyl orange being used as indicator. The combustion of all the petrol is assured by burning the petrol-alcohol mixture to dryness, and afterwards burning two or three successive small quantities of alcohol alone in the lamp. The method is stated to be quick and to give reliable results. *Calorific value* is determined in the bomb calorimeter. The pressure should be at least 25—30 atmospheres to ensure complete combustion. The spirit may be introduced into the platinum capsule of the bomb by means of a Lunge and Rey pipette, or may be sealed in a thin glass bulb which collapses on charging the bomb with oxygen. *Olefines* are usually estimated by shaking the spirit with an equal volume of strong sulphuric acid in a graduated tube and noting the decrease in volume of the spirit; by the bromine or iodine absorption method; or by shaking the spirit frequently for about 15 minutes with a standard solution of potassium permanganate acidified with sulphuric acid, and then titrating the excess of permanganate with ferrous ammonium sulphate. All three methods are affected by secondary reactions and give only approximate results. *Aromatic hydrocarbons* may be determined by sulphonation and nitration methods, or by extraction at low temperatures with liquid sulphur dioxide and separation by fractional distillation. All these methods are easy of manipulation and give fairly reliable results. *The spontaneous ignition temperature* (this J., 1917, 109) is the lowest temperature to which a platinum crucible must be heated in order that when a drop of the petrol is allowed to fall into the crucible an explosion will occur. This temperature is of great interest to automobile engineers, with relation to the compression limits, but further experiments are required before the method can be employed as a standard test.—T. ST.

Toluol by cracking solvent naphtha in the presence of blue gas. G. Egloff. J. Ind. Eng. Chem., 1918, 10, 8—9.

THE author suggests the use of water-gas plants for the production of toluol by cracking solvent (coal-tar) naphtha in the presence of blue gas. From fifteen million galls. of solvent naphtha, the calculated produce of 1917, two million gallons of toluol could be produced, a more than sufficient number of carburetted water-gas plants for this purpose being already in operation in the United States. A test run on a Lowe 6 ft. carburetted water-gas plant over a period of 48 hrs. gave 57% of light oil containing benzol, 14.5% toluol, 23.7%; solvent naphtha, 19.8%; heavy naphtha, 9.7%; "dead" oil, 14.0%. The plant had a capacity of 500,000 cub. ft. per 24 hrs., and the amount of solvent naphtha used was 6000 galls., or 12 galls. per 1000 cub. ft. of gas produced.—L. A. C.

Acetylene; Storage of dissolved —. Home Office Report.

THERE are practically only three porous materials in use for absorption of dissolved acetylene in the United Kingdom: (A) a porous agglomerate of asbestos, kieselguhr, and charcoal, and a suitable cement; (B) charcoal filling; (C) kapok filling. These are satisfactory, but only the most suitable form of charcoal should be used. A sample of

each porous material allowed should be deposited at the Home Office. The porosity should not exceed 80%. Acetone is the most suitable commercially procurable solvent; substitutes should be allowed, but mixtures of various solvents are inadvisable. The solvent must not completely fill the porous material under any rise of temperature likely to be experienced. With the present type of cylinder, the pressure at present allowed, i.e., 150 lb. per sq. in., should not be increased; for solid drawn cylinders and for those of 100 cub. ft. capacity and over in which the acetylene-welding at the top and bottom is strengthened, the pressure allowed might safely be increased to 225 lb. per sq. in., provided a solvent is used in addition to the porous material. The pressure allowed should be stated at 60° F. (15.5° C.). The best material for the construction of cylinders is a mild steel of high ductility, of which the carbon content does not exceed 0.25%, and the phosphorus and sulphur each do not exceed 0.05%. The test pressure should be four times the working pressure and should be maintained for not less than fifteen minutes; re-testing, beyond visual examination, is not necessary. The use of acetylene-welded cylinders should be discontinued as soon as possible; those in use at present should be strengthened at the joints by spinning them over. Fusible plugs should not be used. Filling stations should be approved by, and subject to inspection by, the Home Office. Imported cylinders should be certified by the importer that they comply with regulations. One company recharging cylinders manufactured by another company should first obtain information as regards porous material and solvent. Records of cylinders, all of which should be marked, should be kept, and the use of cylinders for any other purpose should be prohibited. The charging of cylinders by the application of low temperature should be allowed.—L. A. C.

PATENTS.

Fuel briquettes from combustible waste products; Production of—. O. A. Tollefsen, Christiania. Eng. Pat. 112,514, Jan. 17, 1917. (Appl. No. 862 of 1917.)

FUEL briquettes are composed of paper waste 60%, sawdust 20%, tanning bark, fir and pine cones and splinters 15%, and a binder such as resin, flour, or glue 5%. The binder, mixed with water at 60° C., is first added to the paper waste softened in water, the other ingredients are added in succession, and the mixture is briquetted and dried.

Gas-producer. C. W. Lummis and G. H. Isley, Assignors to Morgan Construction Co., Worcester, Mass. U.S. Pat. 1,251,064, Dec. 25, 1917. Date of appl., May 21, 1914.

A U-shaped arm is pivoted at one end about a horizontal axis fixed in the top of the producer, the other end resting on the fuel, and the whole is arranged so that the arm can be moved radially so as to follow changes in the height of the fuel bed, and also horizontally to level the surface of the fuel.—A. B. S.

Oils; Process and apparatus for treating—. O. C. Swan, Assignor to The Swan Process Oil Co., Denver, Colo. U.S. Pats. (A) 1,250,526 and (B) 1,250,527, Dec. 18, 1917. Dates of appl., June 11, 1917, and Feb. 21, 1916.

(A) IMPURE oil is initially heated with a suitable "defecating agent" and passed into a flotation separator in which it is mixed with a charge of an inert absorbent powder. The mixture is then filtered and the oil thus purified is relieved of its

naphtha content by distillation, the still residue being treated as before. (B) Impure oil is filtered and passed into a treating tank in which it is mixed by agitation with a highly buoyant and absorptive material; it is then passed into a flotation separator tank in which the heavier impurities are precipitated. The top layer of oil flows into a pressure filter of the type having replaceable bag-covered frames, whereby remaining colloidal and other suspended impurities are removed.—L. A. C.

[Petroleum] hydrocarbons; Distilling—. J. W. Coast, jun., Tulsa, Okla., Assignor to The Process Co. U.S. Pat. 1,250,798, Dec. 18, 1917. Date of appl., Oct. 23, 1916.

HIGH-BOILING petroleum hydrocarbons are vaporised and cracked under a pressure greater than 50 lb. Steam, at a temperature lower than that of the vapour, is introduced into the retort above the liquid level, so that the hydrocarbons of relatively high boiling point condense and return for further cracking treatment. The remaining vapour is removed and condensed.—L. A. C.

Petroleum hydrocarbons; Art of and apparatus for cracking—. J. W. Coast, jun., Tulsa, Okla., Assignor to The Process Co. U.S. Pats. (A) 1,250,799 and (B) 1,250,800, Dec. 18, 1917. Dates of appl., Dec. 11 and 18, 1916.

HYDROCARBON vapours are led off from a retort under a pressure greater than 50 lb. per sq. in., through an air-cooled reflux condenser or series of condensers, and then through a steam chamber supplied with superheated steam. The high-boiling hydrocarbons are condensed and returned to the retort through the condenser. The steam and low-boiling hydrocarbons are conducted to a main condenser under atmospheric pressure. A pressure-regulating valve is situated between the steam chamber and main condenser.—L. A. C.

Petroleum hydrocarbons; Cracking—. J. W. Coast, jun., Tulsa, Okla., Assignor to The Process Co. U.S. Pat. 1,250,801, Dec. 18, 1917. Date of appl., May 5, 1917.

RELATIVELY cool steam is forced into hydrocarbon vapours (produced by heating hydrocarbons in a retort) confined at a pressure greater than two atmospheres; the condensed portions are returned to the still and the remaining mixture of steam and vapour is cooled (under pressure) to condense an intermediate fraction. Relatively cool steam is then forced into the remaining mixture of steam and vapour, also under pressure, and the steam and hydrocarbon vapour are condensed.—L. A. C.

Hydrocarbons; Method of and apparatus for fractionating—. L. E. Hirt, Los Angeles, Cal. U.S. Pat. 1,250,879, Dec. 18, 1917. Date of appl., Oct. 21, 1916.

PREHEATED oil vapour is subjected to the action of an electric arc within a closed chamber or retort under regulated pressure, chlorine gas also being admitted to the chamber. The vapours are withdrawn and serve to preheat the oil supply.—L. A. C.

Coal and the like; Process for producing liquid or soluble organic combinations from hard—. F. Bergius and J. Billwiler, Hanover, Germany. U.S. Pat. 1,251,954, Jan. 1, 1918. Date of appl., Aug. 3, 1914.

SEE Eng. Pat. 18,232 of 1914; this J., 1916, 167. A temperature of less than 600° C. and a pressure exceeding 20 atmospheres are specified.

Peat: Treatment of —. T. Rigby, Dumfries, Assignor to Wetcarbonizing, Ltd., London. U.S. Pats. 1,251,285 and 1,251,422, Dec. 25, 1917. Dates of appl., May 7 and July 14, 1914. SEE Eng. Pat. 11,133 of 1913; this J., 1914, 912.

Process and means for the separation and recovery of liquids of different densities and the separation of light solid particles from a heavy liquid. Eng. Pat. 103,670. See I.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

PATENTS.

Wood distillation. H. O. Chute, New York. Assignor to K. P. McElroy, Washington. U.S. Pat. 1,250,282, Dec. 18, 1917. Date of appl., May 23, 1910. Renewed May 19, 1917.

THE vapours generated during the distillation of wood are passed into a bell reservoir at a rate proportional to their speed of production. They are cooled in the reservoir to a temperature above the boiling point of pyroligneous acid and then passed through a scrubber against a counter-current of tar oils to remove tar. The flow of vapours through the scrubbers is effected by suction controlled by the bell reservoir. The tar is fractionated and the oil fraction used for scrubbing the vapours.—L. A. C.

Charcoal: Preparation of vegetable —. T. E. Rule and J. Nicol, Liverpool. Assignors to A. H. Bonnard, London. U.S. Pat. 1,250,228, Dec. 18, 1917. Date of appl., July 11, 1916.

SEE Eng. Pat. 10,622 of 1915; this J., 1916, 1212.

Baking-furnace [for carbons, etc.]. U.S. Pat. 1,251,309. See I.

III.—TAR AND TAR PRODUCTS.

Toluol by cracking solvent naphtha. Egloff. See IIA.

PATENTS.

Liquid mixtures [tar]; Apparatus for the fractional uninterrupted distillation of —. W. Rothenbach, Florence, Italy. Eng. Pat. 106,088, Mar. 29, 1917. (Appl. No. 4562 of 1917.) Under Int. Conv., Apr. 15, 1916.

LIQUID to be distilled, e.g., tar, passes from a reservoir first through the outer parts of the condensers of the system to preheat it, thence to the top of a distilling column or retort, and then to a second similar column. The heating fluid, which may be superheated steam or combustion gases initially at 300°–100° C., is passed through the columns in the opposite direction to the liquid, and the liquid is distilled in a partial vacuum which gradually diminishes to atmospheric pressure in the direction traversed by the liquid, i.e., in the direction of increasing density. The distillation products are withdrawn as separate fractions at four points of the system, and passed into the condensers mentioned above.—W. F. F.

Pitch: Cooling, solidification and delivery of —. J. L. Major, Hull. Eng. Pat. 112,370, May 3, 1917. (Appl. No. 6314 of 1917.)

THE hot pitch is run into moulds carried on the band of a conveyor or by a drum or in any other

suitable manner, and after cooling and solidification, the blocks of pitch are discharged from the moulds by their own weight.—W. H. C.

Toluol and like hydrocarbons; Manufacture of —. F. Thuman, London. From O. B. Evans, Philadelphia, U.S.A. Eng. Pat. 112,878, Apr. 20, 1917. (Appl. No. 5568 of 1917.)

Method and apparatus for fractionating hydrocarbons. U.S. Pat. 1,250,879. See IIA.

IV.—COLOURING MATTERS AND DYES.

Coupling reaction; Mechanism of the —. O. Dimroth, H. Leichtlin, and O. Friedemann. Ber., 1917, 50, 1531–1548.

DIMROTH supposes that in the first stage of the coupling of a diazonium salt with a phenol a diazo-ether is formed, which would subsequently change into the ordinary azo-compound under suitable conditions. Thus, in the case of *p*-nitrophenol and *p*-bromobenzenediazonium chloride, the intermediate, primary product has actually been isolated: $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{O}\cdot\text{N}_2\cdot\text{C}_6\text{H}_4\text{Br} \rightarrow \text{NO}_2\cdot\text{C}_6\text{H}_4(\text{OH})\cdot\text{N}_2\cdot\text{C}_6\text{H}_4\text{Br}$. Auwers has raised the question, however, whether the primary products are ethers, $\text{R}\cdot\text{O}\cdot\text{N}$: $\text{N}\cdot\text{R}'$, or diazonium salts, $\text{R}\cdot\text{O}\cdot\text{NR}'$: N , and a reply is now given. Morgan and Wootton's stable diazonium salts, 4-benzoylamino-naphthalene-1-diazonium and *p*-acetylaminobenzenediazonium chlorides, have been treated with phenols ranging in strengths from picric acid to pentamethylphenol. The molecular conductivities of the products in 80% acetone have been measured, and the results show that the compounds with picric acid and dinitrophenol are true diazonium salts, with the same conductivities as the chlorides, or trichloroacetates, whereas the weaker phenols and certain enols give true ethers, with conductivities as low as that of *p*-nitrobenzeneazo-methyl ether. —J. C. W.

β -Naphthylamine; Studies on the sulphonation of —. A. G. Green and K. H. Vakil. Chem. Soc. Trans., 1918, 113, 35–44.

ON sulphonation of β -naphthylamine at temperatures from 20° to 80° C. there was only a slight variation in the proportion of the 2.8- to the 2.5-monosulphonic acids, which together constituted 97–99.5% of the sulphonation product; similar results were obtained for variations of the time from 1 to 10 hrs. Between these limits of temperature and time, the strength of the sulphuric acid appeared to exert little influence, except at 80° C. when an increase in the concentration of sulphur trioxide gave a slightly increased amount of the 2.6- and 2.7-isomerides. The lowest temperature and shortest time of reaction appeared to favour the production of the 2.5-acid. If the temperature of sulphonation is above 80° C. or the time of reaction at 80° C. more than 10 hrs., the percentage of 2.8-acid decreases, whilst that of the 2.5-isomeride increases; this is accompanied by an increased production of the 2.6- and 2.7-acids, the quantity of which reaches 7.5% with 96% sulphuric acid at 120° C. The proportion of the 2.8-acid depends on the proportion formed initially and the subsequent conversion of the 2.8- into the 2.5-acid, the latter factor only becoming prominent above 80° C., or on heating at 80° C. for more than 10 hrs., or by the use of a higher concentration of sulphur trioxide. The presence of the 2.1-acid in the sulphonation product could not be detected, and its behaviour on heating with sulphuric acid indicates that its isomerisation is due to hydrolysis and subsequent

resulphonation; the sulphonic group must therefore enter the second nucleus directly, and not through intermediate formation of the homo-nuclear isomeride. An equilibrium is not established between the 2.8- and 2.5- acids in sulphuric acid solution, as the isomerisation only occurs from the 2.8- to the 2.5-acid. The relative facility with which the isomeric acids undergo hydrolysis to β -naphthylamine is expressed as follows: $2.1 > 2.8 > 2.5 > 2.6$ and 2.7. It is concluded that the gradual conversion of the 2.8- into the 2.5-acid at 80° – 120° C. is due to repeated hydrolysis of the 2.8-acid and resulphonation of the β -naphthylamine produced, which gives about 60% of the 2.5-acid. This is accompanied to a small extent by isomerisation to the 2.6- and 2.7-acids, especially when sulphuric acid of high concentration is employed at above 120° C., until at 150° – 160° C. they constitute the main sulphonation product; their formation is probably due to concurrent disulphonation and hydrolysis, in which case the 2.6-acid would originate from the 2.8-acid, and the 2.7-acid from the 2.5-acid. The reactions of the sodium salts of the four isomerides with copper sulphate and silver nitrate are described.

—F. W. A.

Iso-oxadiazole oxides and iso-oxadiazoles; Nitro-derivatives of—, A. G. Green and F. M. Rowe. Chem. Soc. Trans., 1918, 113, 67–71.

REDUCTION of the dinitro-derivative of benzo-oxadiazole oxide with titanous chloride has proved that the compound does not contain a hydroxyl group, as was suspected from its acidic function; the compound is therefore a true dinitrobenzo-oxadiazole oxide in which a hydrogen in the benzene ring possesses acidic properties. The dinitro-deriv. of naphthiso-oxadiazole oxide (I.) and two mono- and the di- (II.) derivatives of naphthiso-oxadiazole have been prepared, and probably have the following constitution:—

—F. W. A.

Phenazoxonium and its simplest derivatives. F. Kehrman and A. Boubis. Ber., 1917, 50, 1662–1667. (Compare this J., 1914, 687; 1915, 654, 792.)

It was proved a year or two ago that phenazothionium forms both *meri*- and *holo*-quinonoid salts, and consequently a revision of other theories and spectrographic data in the case of phenazoxonium became necessary. The present chemical and optical investigations (see also following abstract) show that phenazoxonium is also normal in its behaviour towards acids. The reddish-violet salts obtained by dissolving phenazoxine in sulphuric acid, whether dilute or concentrated, are *meri*-quinonoid, mono-acid salts. If hydrogen peroxide is added to the solutions in concentrated sulphuric or perchloric acids, yellow, *holo*-quinonoid, di-acid salts are formed. These are unstable but can be preserved for a short time at 0° – 10° C. If glacial acetic acid is added to these yellow solutions, the colour changes to wine-red, *holo*-quinonoid, mono-acid salts being

formed. The perchlorate, $C_6H_4 \begin{array}{c} \diagup N \\ \diagdown O \end{array} C_6H_3$, ClO_4

may even be isolated, as an explosive, brown powder. Similar behaviour is shown by 3.9-dimethyl- and 5- and 3-amino-phenazoxoniums.

—J. C. W.

Quinoneimide dyes. VII. Spectra of the simplest azoxine dyes. VIII. Supplementary observations on the absorption spectra of the simplest azothionium compounds. IX. Absorption spectra of the mono-acid salts of 3.9-diaminophenazoxonium. F. Kehrman and M. Sandoz. Ber., 1917, 50, 1667–1673, 1673–1682, and 1682–1683. (Compare preceding abstract.)

AN account, with tables and curves, of the absorption spectra of the salts of phenazoxonium, 3.9-dimethyl- and 3- and 5-amino-phenazoxoniums; phenazothionium, 6-methyl- and 5-amino-phenazothioniums; 3.9-diaminophenazoxonium monohydrochloride, 3-amino-9-anilinophenazoxonium 9-hydrochloride, 3.9-dianilinophenazoxonium monohydrochloride, 3.9-tetramethyldiaminophenazoxonium nitrite, and 3-dimethylamino-9-anilinophenazoxonium 9-monohydrochloride. In many cases the data correct earlier notices. All the phenazothioniums behave alike in the ultra-violet, exhibiting a band at λ 290 $\mu\mu$, whilst the phenazoxoniums are all alike in giving two bands, at λ 265 and 285 $\mu\mu$.—J. C. W.

α -Naphtholphthalein; Preparation of —, E. A. Werner. Chem. Soc. Trans., 1918, 113, 20–21.

IN place of the phthalyl chloride used by Grabowski (Ber., 1871, 4, 725; 1873, 6, 1065), phthalic anhydride was used. A mixture of 7 grms. of α -naphthol and 3.8 grms. of phthalic anhydride was treated with 0.75 c.c. of concentrated sulphuric acid for 4 hrs. below 65° C. After extraction with water to remove sulphuric acid, the semi-solid mass was digested with 0.5% caustic soda at 70° C.; 0.8 grm. of Grabowski's "anhydride" (Ber., 1871, 4, 661) was left undissolved. The deep blue solution was treated with dilute hydrochloric acid sufficient to neutralise half the caustic soda, and the phthalein precipitated by means of carbon dioxide. The yield after reprecipitation was 2.3 grms.—F. W. A.

Phthalic acid derivatives; Constitution and colour of —, V., VI., VII. D. S. Pratt and G. A. Perkins. J. Amer. Chem. Soc., 1918, 40, 198–236. (See also J. Chem. Soc., March, 1918.)

Some derivatives of tetrachloro- and tetra-iodophthalimides.—In order to study the absorption spectra of different members of the same family with a view to obtaining a clearer insight into the relation between constitution and colour, the authors have prepared a large number of phthalic acid derivatives. A number of derivatives of tetrachloro- and tetra-iodophthalimides have been prepared and a new type of phthalic acid derivative in which chlorine in the nucleus is replaced by anilino groups. *Action of amines upon dichlorophthalic anhydrides.*—The authors describe the chlorination of phthalic anhydride and the separation of the isomers; the preparation of 3.4-, 3.6-, and 4.5-dichlorophthalanils and the aniline derivatives of the first two, the last giving nothing but tarry products. *Di-iodo-, tri-iodo-, and dichloro di-iodophthalic acids.*—The authors describe the iodation of phthalic acid, of phthalic anhydride, and of the three dichlorophthalic acids, and the separation of the resulting compounds; also the preparation of hydroxyl derivatives and anils of these compounds.—L. A. C.

Phthalic acid derivatives; Constitution and colour of —, VIII., IX., X. D. S. Pratt and A. B. Coleman. J. Amer. Chem. Soc., 1918, 40, 236–251. (See also J. Chem. Soc., March, 1918.)

Tetraiodofluorescein and some of its deriva-

lives.—The authors describe the preparation of tetraiodofluorescein and certain of its salts and derivatives. The compound exists at ordinary temperatures as an unstable mixture of the benzenoid and quinonoid modifications. The hydrate losses water readily to form a yellow hydrous derivative containing one molecule of water of crystallisation; this on heating gives the reddish-brown anhydride. *Tetraiodoococin* and some of its derivatives. *Tetraiodoococin* was prepared by the action of bromine on tetraiodofluorescein suspended in boiling glacial acetic acid. The compound forms canary-yellow crystals of the benzenoid modification. *Tetraiodoerythrosin* (octaiodofluorescein) and some of its derivatives.—Iodine substitution products of fluorescein have been made commercially by methods of electrolysis for use as dyes; these, however, are mixtures and contain no iodine in the phthalic residue. Pure tetraiodoerythrosin was prepared by treating tetraiodofluorescein with iodine and iodic acid in absolute alcohol and heating under a reflux condenser. A lower halogenated product was obtained as a by-product.—L. A. C.

Phthalic acid derivatives; Constitution and colour of.—XI. *Phenoltetraiodophthalein and some of its derivatives*. D. S. Pratt and A. F. Shupp. J. Amer. Chem. Soc., 1918, 40, 254—264. (See also J. Chem. Soc., March, 1918.)

THE authors describe the preparation of pure phenoltetraiodophthalein, its dinitro-, tetra-nitro-, tetrabromo-, and tetraiodo-derivatives, and their diacetates, dibenzoates, and dimethyl ethers. Tetraiodofluoran was obtained as a by-product.—L. A. C.

PATENTS.

Dyestuffs [from algæ]. N. Malcolmson, London. Eng. Pat. 112,474, Oct. 10, 1916. (Appl. No. 14,390 of 1916.)

A DYE paste or pulp is obtained from marine algæ by injecting steam into the raw untreated weed, with or without subsequent evaporation. Dye liquors are obtained from olive, brown, or red algæ by boiling the weed with an acid solution and then treating with a hot alkaline solution. In the case of olive and brown algæ, the solution produced by treatment with acid may be evaporated to one-half to one-eighth its bulk, when the dyestuff obtained gives a shade different to that obtained if this step is omitted.—F. W. A.

Sulphur dyes; Manufacture of.—H. Heimann, Dessau, Assignor to Act.-Ges. f. Anilin-Fabr., Berlin, Germany. U.S. Pats. (A) 1,251,368 and (B) 1,251,369, Dec. 25, 1917. Date of appl., Jan. 21, 1915.

SULPHURISED dyes giving olive to brown shades are obtained by the action of sulphur on a mixture of (A) an amino or (B) an aminonitro derivative of the benzene-azo-naphthalene series with an aromatic C-alkylated diamine. The dyestuffs from (A) benzene-azo- α -naphthylamine and (B) *m*-nitrobenzene-azo- α -naphthylamine with *m*-toluylenediamine are specially claimed; they produce brown shades on cotton, fast to washing and to boiling dilute acids.—F. W. A.

Aniline dyestuffs; Manufacture of.—D. de Nagy, Assignor to A. E. King and G. H. Odell, London. U.S. Pat. 1,250,289, Dec. 18, 1917. Date of appl., June 28, 1917.

SEE Eng. Pat. 16,203 of 1915; this J., 1917, 78.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Velveteens; Ignition and combustion of—in hermetically sealed tin cases. W. Thomson. J. Soc. Dyers and Col., 1918, 34, 6—7.

A CASE of ignition of velveteens packed in a hermetically sealed tinned iron case for shipment has been investigated. It was found that samples of black velveteen in a tin case could be ignited by the soldering iron used in sealing the case. Whereas the smouldering of velveteens dyed in colours gradually becomes extinguished, the iron oxide present in black velveteen, dyed with Logwood Black and topped on the pile with Prussian Blue, has the effect of continuing the combustion until only ash remains.—F. W. A.

Wood; Constituents of—which give colour reactions. II. H. Wichelhaus and M. Lange. Ber., 1917, 50, 1683—1685. (Compare this J., 1916, 1151.)

By the passage of steam at 180°—200° C. through pine or fir wood, a distillate is obtained which contains substances that give colour reactions with phloroglucinol and hydrochloric acid. The less volatile third of the liquid gives a typical cherry-red precipitate, and also a brick-red substance, $C_{15}H_{15}O_8N_8$, on adding *p*-nitrophenylhydrazine. This is apparently a derivative of a keto-furfuraldehyde, $C_8H_8O_5$, which would be related to a hexose thus: $C_6H_{12}O_6 - H_2O + O = C_8H_8O_5 + H_2O$.—J. C. W.

PATENTS.

Fabric for aeroplanes, kites and the like; Method of manufacturing and after-treating.—R. Wheatley, Edinburgh. Eng. Pat. 112,483, June 1, 1917. (Appl. No. 17,503 of 1916.)

AEROPLANE fabric and the like is treated with solutions of acetylcellulose or nitrocellulose or both and of a suitable protective colouring substance or substances soluble in the solution and in the dried dope, to protect the dope against deleterious incident radiation. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pat. 105,137; this J., 1917, 544.)—F. W. A.

Cotton-stalks; Process and apparatus for reducing—to pulp suitable for the manufacture of paper. J. M. Irwin, Dallas, Tex. U.S. Pat. 1,250,106, Dec. 18, 1917. Date of appl., Sep. 14, 1916.

COTTON stalks are placed in a container in which hydration and chemical treatment are effected and the mass is alternately compressed, first from one end of the container and then from the other, and during the alternate compression periods the individual stalks and fibre body of the mass are caused to pass through and between "moving interstices of the container," setting up such a frictional engagement between the stalk or fibre body and the machine element as to cause the tentacles and fibre to be drawn and abstracted from the body of the stalk. In the container a shaft is arranged axially, carrying two attrition wheels provided with oppositely turned blades, adapted to travel along the shaft contiguously with each other and revolving in opposite directions.—J. F. B.

Sulphite-cellulose liquors; Purifying exhausted.—A. G. Bloxam, London. From Zellstoff-fabrik Waldhof, Mannheim-Waldhof, Germany. Eng. Pat. 112,395, Aug. 10, 1917. (Appl. No. 11,537 of 1917.)

WASTE sulphite liquor is freed from calcium salts by treatment with sodium carbonate, then concentrated to a density of about 30° B. (sp. gr.

1:246) and stirred with sufficient sulphuric acid to convert all the salts into sulphate. The mass is cooled while stirring, and the sodium sulphate is allowed to crystallise out from the liquor, which is left at rest at a low temperature for a period ranging from a few hours to several days.—J. F. B.

[Hydr]oxylignin and [hydr]oxylignon from lignin and lignon sulphonates [in sulphite cellulose waste liquor]; Method of preparing —. E. Oman, Stockholm, Sweden. Eng. Pats. (A) 103,649 and (B) 103,650, Jan. 4, 1917. (Appl. Nos. 181 and 182 of 1917.) Under Int. Conv., Jan. 12, 1916.

SULPHITE-CELLULOSE waste liquor is saturated with sodium chloride and heated to 40°–50° C.; a portion of the sulphonates, amounting to 33–50% of the total sulphonates present, is salted out in the form of a grey flocculent precipitate. The precipitated sulphonates are called ligninsulphonates and the soluble sulphonates lignonsulphonates. (A) Fifty parts of the precipitate containing about 60% of ligninsulphonate and 40% of sodium chloride is mixed with a 50% solution of sodium hydroxide, 300 parts, and 15 parts of potassium chloride, and the mixture is fused at 140°–160° C. for 2–3 hours; the hydroxylignin is precipitated by acidification after dissolving the melt in water. (B) The salt solution containing the lignonsulphonate is concentrated to about one-sixth of its volume and the sodium chloride is removed; 1 litre of the solution is treated with 750 grms. of solid sodium hydroxide and 60 grms. of potassium chlorate, and the sulphonic groups are eliminated by fusion as above.—J. F. B.

Lignin and lignon sulphonic acids or their salts; Method of preparing nitro compounds from —. E. Oman, Stockholm. Eng. Pats. (A) 103,651 and (B) 103,652, Jan. 4, 1917. (Appl. Nos. 202 and 203 of 1917.) Under Int. Conv., (A) Jan. 15 and (B) Jan. 20, 1916.

(A) 100 GRMS. of sodium ligninsulphonate (see preceding abstract) of about 60% concentration is added gradually, with stirring and cooling, to 200 grms. of 50% nitric acid, at 30°–40° C. The nitrated compound is partly deposited, and the remainder is extracted by neutralising the solution and precipitating with an equal volume of alcohol. (B) 200 c.c. of the filtrate from the waste sulphite liquor after separation of the ligninsulphonate, concentrated to $\frac{1}{2}$ of its volume, is added gradually, with stirring and cooling, to 500 grms. of a nitrating acid prepared from 1.5 parts of sulphuric acid of sp. gr. 1.84, and 1 part of nitric acid of sp. gr. 1.4, at 30° C. The nitro-compound is precipitated directly, or if nitric acid alone has been used, the product may be precipitated by alcohol after neutralisation.—J. F. B.

Lignin sulphonates prepared from sulphite-cellulose waste lye; Method of treating — so that they may be dried without decomposition. E. Oman, Stockholm. Eng. Pat. 103,655, Jan. 4, 1917. (Appl. No. 206 of 1917.) Under Int. Conv., Jan. 15, 1916.

THE ligninsulphonates precipitated by salt from sulphite-cellulose waste liquor tend to blacken during drying, owing to the presence of free acid which cannot be removed by washing the precipitate with sodium chloride solution. This defect may be overcome by washing the precipitate with saturated sodium chloride solution or alcohol containing free alkali, such as sodium hydroxide or carbonate.—J. F. B.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Combustibility of cotton; Influence of certain processes of dyeing on the —. G. E. Holden. J. Soc. Dyers and Col., 1918, 34, 7–9.

THE rate of burning of dyed cotton was not accelerated by the presence of tannates of aluminium, antimony, and tin, but was considerably increased by the tannates of iron, manganese, lead, and copper. Probably owing to the relatively small amounts of copper or chromium precipitated on the fibre, no appreciable effect was produced by the after-treatment of substantive and sulphide dyeings with copper sulphate and bichromate respectively. Details of possible sources of certain metals in dyed cotton material are given. In determining the suitability of the various dyeing processes for certain materials, the ultimate destination should be taken into account, and the "burning test" should receive more attention.—F. W. A.

Cotton-fibre; Case of mechanical powdering [during beetling] of the —. M. Fort. J. Soc. Dyers and Col., 1918, 34, 9–10.

IF, owing to the breaking of a traverse during beetling, the hammers fall continuously on the same sector of the cloth beam, the temperature rises, and conditioning moisture is lost; the subsequent yellowing takes place more rapidly with linen than with cotton. The formation of "chalky" patches on the cloth by beetling is accounted for by the breaking down of fibres, and is assisted by tendering during the bleaching process. In the case described, an extraordinary degree of mechanical destruction of full-bleached, unmercerised cotton damasks, sound and free from chlorine and acid, was obtained, due to the breaking of a traverse during beetling. In less than half an hour, a considerable amount of cloth was ruined, and a large deposit resembling lumps of starch was obtained, which was easily crushed to a fine smooth powder with a slight tendency to break in layers. The product contained no undestroyed fibres, but an occasional small shred of cuticle was present; it consisted of particles quite as uniform but much less in size than starch, arranged in clusters, and often approximating to a cylindrical shape. The powder had the chemical properties of cellulose, being dyed by Methylene Blue and Congo Red similarly to ordinary bleached cotton; it was unchanged by boiling with water, and gave negative results to all tests for oxy-cellulose and hydrocellulose; on treatment with cold caustic soda (52° Tw.) the particles swelled but remained undissolved. The product gave no reaction with iodine solution, but after treatment with hydrochloric acid, the yellowish-brown coloration due to dextrin was obtained.—F. W. A.

Analysis of commercial dextrans. Lamb and Harvey. See XVII.

PATENTS.

Bleaching process. H. R. Anders, Perth Amboy, N.J., Assignor to The Roessler and Hasslacher Chemical Co., New York. U.S. Pat. 1,251,614, Jan. 1, 1918. Date of appl., Mar. 24, 1917.

INDUSTRIAL fibres and fibrous materials are wetted out with lime water at an elevated temperature, and then bleached in a bath containing "a substance carrying active oxygen," made alkaline by means of calcium hydroxide.—F. W. A.

Dyeing machines. J. Farrar, Halifax, and A. R. Whitehead, Leeds. Eng. Pat. 112,482, Dec. 6, 1916. (Appl. No. 17,497 of 1916.)

In dyeing machines in which the dye liquor circulates through the material and is heated by

steam from perforated pipes along the bottom of the vat, direct contact of the steam with the material and undue agitation of the liquor are avoided by providing hoods over the steam pipes, or by the use of an additional steam pipe in the circulating chamber to maintain the temperature of the liquor. In the second case the liquor is heated rapidly to the desired temperature by steam from the pipes in the dye-vat before the material is introduced, after which the temperature is maintained by means of the steam pipes, in the circulating chamber.—F. W. A.

Dyestuffs [from alga]. Eng. Pat. 112,474. See IV.

VII.—ACIDS ; ALKALIS ; SALTS ; NON-METALLIC ELEMENTS.

Sulphuric acid ; De-arsenication of —. H. E. J. Cory. Chem. Trade J., 1918, 62, 89—90.

THE old type of de-arsenicating plant, consisting of a tower in which an ascending stream of hydrogen sulphide meets a descending stream of sulphuric acid, is effective with weak acid, but costly, sometimes wasteful of hydrogen sulphide, and limited in output. The modern continuous type, in which the acid is agitated by paddles, giving intimate contact with the gas, is very effective for acid up to 110°—120° Tw. (sp. gr. 1.55 to 1.60), and has the advantages of low initial cost, complete removal of arsenic, continuous output, and low running expenses. A third type of plant, in which hydrogen sulphide is pumped into the acid under pressure, is advantageous when a cheap, abundant supply of the gas is available, and it can be employed with a stronger acid, thus saving fuel in the concentration. It is particularly useful for acid low in arsenic. The minimum storage capacity should be one day's supply of arsenical and purified acid, and the settlers should be capable of holding half a day's output. Settlers, filters, and communicating troughs may all be made of wood lined with lead. Acid made from light arsenical ores may be filtered through porous tiles cemented together by water-glass thickened with lava or volcanic stone. When heavy arsenical ores are handled, pebble filters, composed of graded layers of quartz, supported on thin flat bricks, with "soap bricks" spaced well apart beneath them, are used. When practicable, the treated acid should be filtered warm. Nitrous compounds in the acid are objectionable, as they react with hydrogen sulphide, and interfere with de-arsenication. The strength of the treated acid must not be too high. The process may be controlled by a qualitative Marsh test of the acid leaving the de-arsenicator, and by the colour of the effluent acid and mud. After settling, a quantitative Marsh or modified Gutzeit test should be applied, and if the result is unsatisfactory, the acids should be sent back to the de-arsenicator, or to the mud plant. The closed (pressure type) process needs more careful control. Hydrogen sulphide at about 10 lb. pressure should be blown in until a quantitative Marsh test gives a satisfactory result. Acids low in arsenic can sometimes be conveniently filtered without settling. When high in arsenic, a considerable quantity of arsenical mud is obtained in the settlers and filters. A recent development is the addition of an oil of low specific gravity, e.g., paraffin, to the acid under treatment, which brings part of the sulphide to the top on standing. The arsenical residues are preferably heated in long leaden pans provided with mechanical scrapers, the acid being run off and returned to the de-arsenicator, while the dried residue is either thrown away or sold. Filter-press treatment of the residue is more or less ineffective.—F. Sp.

Sulphuric acid ; Action of dilute — upon a common glass carboy. A. D. Olle. Austral. Pharm. Notes, Sep. 1, 1917, 18.

A SAMPLE of sulphuric acid (sp. gr. 1.18) originally free from iron gave a deep red coloration when oxidised and tested with potassium thiocyanate, and was therefore useless for storage batteries, after it had stood for six years in a green glass carboy. The acid was found to contain 0.00127% iron, 0.0003% of aluminium, 0.0044% of calcium oxide, and 0.0739% of alkalis as Na_2O . Many samples of acid sold as chemically pure were found to contain iron, and iron could be detected in distilled water which had stood for some time in glass vessels.—C. A. M.

Hydrofluosilicic acid ; Case of poisoning by — and detection of this acid in animal organs. E. Spaeth. Pharm. Zentralh., 1917, 58, 599—601.

A BOY died soon after drinking a quantity of a disinfectant solution sold under the name of "Montanin," and consisting of a 27% solution of hydrofluosilicic acid. From the stomach and intestines of the boy a quantity of silica corresponding with 1.33 grms. of hydrofluosilicic acid or 4.8 grms. of the original solution was separated. The presence of the acid was detected by extracting the organs with 50% alcohol, filtering the solution, extracting the fat with petroleum spirit, and testing the solution with dilute potassium chloride solution; potassium silicofluoride separated after some time as a clear gelatinous precipitate. Barium chloride gave a white precipitate of barium silicofluoride, whilst ammonia yielded a precipitate of hydrated silica. The filtrate from the latter was treated with milk-of-lime, and evaporated to dryness in a platinum basin; the residue, when treated with sulphuric acid, yielded vapours of hydrofluoric acid. Determination of the silica was found to be the best means of ascertaining the quantity of the acid present in the organs.

—W. P. S.

Hydrogen cyanide ; Detection of small amounts of —. I. M. Kolthoff. Pharm. Weekblad, 1917, 54, 1157—1171. (Compare Anderson, this J., 1916, 1083.)

A DETAILED investigation of methods for the detection of hydrocyanic acid has been carried out in order to ascertain the relative delicacy of the various tests. The Prussian blue test is characteristic for hydrocyanic acid. Identification as ferric thiocyanate is also characteristic, but in presence of thiocyanates (e.g., in saliva, etc.), the hydrocyanic acid must be redistilled from borax solution. The picric acid test is not specific for hydrocyanic acid, but is given by many reducing agents, such as sulphurous acid, aldehydes, acetone, and hydrogen sulphide, of which the last-named may be removed by a cadmium solution; a negative result is hence of more value than a positive reaction, and a blank test must be made on the reagents used. The reaction with guaiacum tincture is not typical for hydrocyanic acid, being given by oxidising agents (halogens, ozone, etc.), and by ammonia, cigar smoke, etc.; a negative result has been stated to indicate the absence of hydrocyanic acid, but the reaction may be affected by the presence of certain reducing agents, and is therefore not conclusive. The phenolphthalein reaction is affected by hydrogen sulphide, which may, however, be removed by a cadmium solution; it is more characteristic than that with guaiacum tincture, as halogens or hydrogen peroxide do not give a red coloration; it is found, however, that these and similar substances may prevent the reaction with the hydrocyanic acid. The silver cyanide reaction is not specific for hydrocyanic acid: in presence of chloride, the hydro-

cyanic acid may be redistilled from a borax solution. The amyl iodide reaction is given by various reducing agents; the appearance of a blue coloration on acidifying the solution indicates hydrocyanic acid, the reaction being specific in the aqueous distillate.—P. W. A.

Potassium salts; Existence of bischofite deposits and the secondary transformations of the Zechstein —. M. Róza. Z. anorg. Chem., 1917, 101, 276—284.

THERE is no reason to suppose that bischofite ($\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$) was among the primary separation products in the potassium salt deposits. The secondary metamorphoses which are supposed to have taken place can be explained without the assumption of a primary bischofite. The "principal" salt deposit, which is 16 metres thick, contains 56% of carnallite, 13.3% of kieserite, and 28.7% of rock salt. This is certainly a primary deposit, and was at one time of vast extent. In spite of the rapid development of the potassium mining industry, very few sections of the deposits have been opened up to geological and chemical-petrographic examination. (See also J. Chem. Soc., March, 1918.)—E. H. R.

Sodium sulphate—ammonium sulphate; Invariant equilibria in the ternary system; water —. C. Matignon and F. Meyer. Comptes rend., 1918, 166, 115—119.

THE co-ordinates of the triple point for each of the possible combinations of three solid phases have been determined and are shown on a trilinear diagram. The authors have determined the temperature of the eutectic of ice and ammonium sulphate and find it to be -18°C . (See also J. Chem. Soc., March, 1918.)—W. G.

Rare earths; Electrolysis of solutions of the —. III. L. M. Dennis and A. B. Ray. J. Amer. Chem. Soc., 1918, 40, 174—181.

IT has been found that the electrolysis of neutral solutions of the nitrates of the rare earths with a mercury cathode is accompanied by a fractional separation of the rare earth hydroxides at the surface of the cathode. The average atomic weight of the rare earth metals in the successive fractions diminishes as the electrolysis proceeds. Violent agitation of the mercury surface increases the efficiency of the fractionation. When solutions containing the nitrates of thorium and the rare earths are similarly electrolysed, the thorium is concentrated in the early fractions. (See also J. Chem. Soc., March, 1918.)—H. M. D.

Gluceium [beryllium] nitride. A. C. Vournasos. Bull. Soc. Chim., 1917, 21, 282—288.

BERYLLIUM nitride may be readily prepared by passing cyanogen over metallic beryllium heated at 800°C . Another general method of preparation of nitrides is by the partial oxidation of a metallic cyanide, or of a carbide in the presence of nitrogen. Thus by heating zinc cyanide or calcium carbide or barium cyanamide with ammonium nitrate the corresponding nitride is obtained in each case. (See also J. Chem. Soc., March, 1918.)—W. G.

Mercuric ion; Rapid characterisation of the — in insoluble sulphates. Application to the identification of this ion in general. G. Denigès. Bull. Soc. Chim., 1918, 23, 36—39.

IF a 10% solution of mercuric nitrate in dilute nitric acid (1 in 100) is added to an insoluble sulphate, yellow turpeth mineral (basic mercuric sulphate) is formed at once in the cold with calcium or mercurous sulphates, slowly in the cold with strontium and lead sulphates, and only slowly on boiling with barium sulphate, and may be identified, if necessary, by microscopical examination.

Soluble sulphates in a mixture may be first precipitated as barium sulphate and then detected as described. (See also J. Chem. Soc., March, 1918.)—W. G.

Mercury ammonia compounds. M. C. C. Holmes. Chem. Soc. Trans., 1918, 113, 71—79.

ON saturating an ethereal solution of mercuric chloride with ammonia, the resulting precipitate has a composition approximating to that of "fusible precipitate," $\text{HgCl}_2 \cdot 2\text{NH}_3$. By digesting "infusible precipitate," HgCl_2NH_2 , at 100°C . with a solution of mercuric chloride (120 to 130%) in a saturated solution of ammonium chloride, filtering the hot liquid from the undissolved precipitate, and allowing it to cool slowly, crystals with the composition $3\text{HgCl}_2 \cdot 2\text{NH}_3$ are obtained. It is improbable that any stable compound intermediate between this and "fusible precipitate" exists. A repetition of Strömholm's work (Z. anorg. Chem., 1908, 57, 72) has confirmed the existence of the compound, $\text{Hg}_2\text{Cl}_3\text{NH}_2$, described by him.—C. A. M.

Phosphorus; Black —. A. Smits, G. Meyer, and R. T. Beck. Proc. k. Akad. Wetensch., Amsterdam, 1918, 20, 392—393.

THE further investigation of the relation of Bridgman's black phosphorus (this J., 1916, 838) to the violet modification has shown that the black form is metastable in reference to the violet at temperatures between 380° and 480°C . Even in presence of iodine, which acts as catalyst, the transformation of black into violet phosphorus takes place, however, very slowly at these temperatures. (See also J. Chem. Soc., March, 1918.)—H. M. D.

PATENTS.

Oralic acid; Process for the production of —. C. T. Thorssell and H. L. R. Lunden. Gottenborg, Sweden. U.S. Pat. 1,251,938, Jan. 1, 1918. Date of appl., Aug. 13, 1915.

A MIXTURE of sodium oxalate, sodium carbonate, and sodium hydroxide is treated with a solution containing sodium bisulphate and sulphuric acid so as to form acid sodium oxalate and sodium sulphate. A portion of the acid sodium oxalate is separated by crystallising, and the remainder is recovered by neutralising the solution and converting it into an insoluble oxalate.—A. B. S.

Hydrosulphite; Manufacture of anhydrous sodium —. E. F. and H. W. Ehrhardt, Birmingham. Eng. Pat. 112,491, Jan. 5, 1917. (Appl. No. 266 of 1917.)

IN Eng. Pat. 8816 of 1905 (this J., 1905, 673), a paste of sodium hydrosulphite (containing water of crystallisation) is heated with a saturated salt solution to 50° – 70°C . and filtered. A further amount of sodium hydrosulphite (containing water of crystallisation) is obtained by saturating the hot filtrate with salt and then cooling; the paste of crystals obtained is treated as in the patent mentioned.—F. W. A.

Magnesium compounds [chloride]; Process of extracting — from magnesium-bearing rocks. S. Peacock, Assignor to Bridgewater Chemical Co., Philadelphia. U.S. Pat. 1,250,216, Dec. 18, 1917. Date of appl., Nov. 28, 1916.

A MIXTURE of finely divided magnesium silicate rock with excess of calcium chloride in aqueous solution is heated under a pressure exceeding three atmospheres to produce a solution of magnesium chloride.—W. E. F. P.

Ferric sulphate and sodium sulphate; Process of producing fused —. H. B. Kipper, Muskegon, Mich. U.S. Pat. 1,250,471, Dec. 18, 1917. Date of appl., Oct. 26, 1916.

A MIXTURE of ferric oxide and nitre cake is heated to about 400° C. in a horizontal, cylindrical, rotary chamber fired internally with producer gas.
—W. E. F. P.

Oxide and hydroxide of barium; Process of making —. B. Peacock, Philadelphia, Pa., Assignor to Larowe Construction Co., Detroit, Mich. U.S. Pat. 1,250,642, Dec. 18, 1917. Date of appl., May 27, 1916.

A MIXTURE of barium carbonate and calcium oxide is heated until most of the carbon dioxide is expelled, and then treated with water to produce a solution of barium hydroxide. The insoluble residue is heated with a subsequent charge of mixture.—W. E. F. P.

Aluminium nitride; Production of —. P. R. Hershman, Assignor to Armour Fertilizer Works, Chicago. U.S. Pat. 1,250,874, Dec. 18, 1917. Date of appl., Dec. 22, 1914.

A CHARGE containing aluminiferous material, contained in a closed chamber, is heated by and in contact with producer gas, the latter being preheated to a high temperature.—W. E. F. P.

Cooling apparatus for alkaline aluminate solutions. R. S. Sherwin, East St. Louis, Ill., Assignor to Aluminium Co. of America, Pittsburgh, Pa. U.S. Pat. 1,251,295, Dec. 25, 1917. Date of appl., July 16, 1913. Renewed Apr. 17, 1917.

IN a circulatory system, the lower part of a deep container is connected by means of a suction device with a vertical, external pipe having two valved branches which enter the container at different points above the normal level of the liquid in the vessel. The upper branch terminates in a sprayer and is disposed at some distance above the normal level in order to effect air-cooling of the descending spray; liquid from the lower branch is returned to the container at a point only slightly above the normal level.—W. E. F. P.

Phosphate materials; Process of treating —. H. Blumenberg, jun., Assignor to C. Allen, Los Angeles, Cal. U.S. Pat. 1,251,741, Jan. 1, 1918. Date of appl., June 7, 1917.

FINELY divided tricalcium phosphate is treated with sulphur dioxide in the presence of water to produce calcium sulphite and phosphoric acid.
—W. E. F. P.

Iron sulphide; Method of manufacturing —. N. G. Petinot, Assignor to United States Alloys Corporation, New York. U.S. Pat. 1,252,024, Jan. 1, 1918. Date of appl., Mar. 7, 1917.

IRON sulphide is produced by heating a mixture of iron pyrites and iron oxide, with or without metallic iron.—W. E. F. P.

Method of treating liquids to remove dissolved salts. U.S. Pat. 1,257,486. See I.

Process for purifying clay and other silicious and aluminous earths and ores. Process for purifying aluminous ores, earths, clays, and sand. U.S. Pats. 1,251,057 and 1,251,058. See VIII.

Process for producing cement and potassium compounds. U.S. Pat. 1,250,291. See IX.

Method and apparatus for recovering volatile metallic values in the form of metallic oxides from molten slag. U.S. Pat. 1,250,261. See X.

Process for reclamation of bichromates [from spent tanning liquors]. Eng. Pat. 105,222. See XV.

VIII.—GLASS; CERAMICS.

Action of dilute sulphuric acid upon a common glass carboy. Olle. See VII.

PATENTS.

Glass tank. H. G. Slingluff, Mount Vernon, Ohio, Assignor to Pittsburgh Plate Glass Co., Pittsburgh, Pa. U.S. Pat. 1,251,931, Jan. 1, 1918. Date of appl., Jan. 20, 1914.

A GLASS-MELTING tank, heated regeneratively at one end, supplies the glass to a series of open drawing-tanks at the other end. Deflecting walls projecting from opposite sides of the tank in front of the drawing tanks nearest the heaters prevent the glass from the heated end of the tank from flowing directly into the drawing tanks.—A. B. S.

Glass-drawing apparatus. H. G. Slingluff, Mount Vernon, Ohio, Assignor to Pittsburgh Plate Glass Co., Pittsburgh, Pa. U.S. Pat. 1,251,932, Jan. 1, 1918. Date of appl., May 16, 1916.

A GLASS-DRAWING apparatus partly immersed in the molten glass in a glass-tank, is provided with a block of refractory material having an elongated drawing opening, and with separate blocks moulded at its ends, provided with grooved drawing ledges which lie beneath the edges of the sheet being drawn, whereby a flow of air or molten glass may be directed against the sides of the sheet as it is being drawn.—A. B. S.

Clay and other silicious and aluminous earths and ores; Process for purifying —. *Process for purifying aluminous ores, earths, clays, and sand.* F. Langford, Eureka, Cal. U.S. Pats. (A) 1,251,057 and (B) 1,251,058, Dec. 25, 1917. Dates of appl., Oct. 12 and Nov. 22, 1916.

(A) FERRUGINOUS clays and other aluminous and silicious materials containing iron are washed with a solution containing tannic acid to remove iron compounds, etc. The insoluble residue is treated with a mineral acid, leaving a second insoluble residue rich in silica. (B) Ferruginous clays and other aluminous materials are treated with hot dilute sulphuric acid containing less than 1% of sulphuric acid, which dissolves the iron compounds and impurities with a minimum action on the aluminous compounds.—A. B. S.

Tunnel kiln. J. B. Owens, Metuchen, N.J. U.S. Pat. 1,251,273, Dec. 25, 1917. Date of appl., June 4, 1917.

AN air-circulating space is formed by building a wall along each side of the interior of a tunnel kiln beyond the point of maximum temperature. Air enters this space through an opening in the top of the kiln, and after being heated by radiation from the cooling goods, passes to the furnace and is used for the combustion of the fuel.—A. B. S.

Ceramic mouldable composition. W. M. W. Horn, Teplitz, Austria. U.S. Pat. 1,251,888, Jan. 1, 1918. Date of appl., June 9, 1913.

THE material consists of an intimate mixture of equal parts of finely powdered, burnt fireclay and lean clay, low in quartz, lime, magnesia, and alkalis. It contains a high proportion of alumina and is capable, when moistened, moulded, and baked, of producing finely porous, strong articles.
—A. B. S.

Enamels for enamelling iron. R. Koepp und Co., Oestrich, Germany. Eng. Pat. 100,777, Feb. 18, 1916. (Appl. No. 2437 of 1916.) Under Int. Conv., July 1, 1915.

IN order to reduce the cost of enamels for ironware, the expensive borax and boric acid and the felspar are replaced by a soft glass rich in alkali which is melted along with other constituents. If

necessary, clay is added to replace the alumina contained in the felspar. Quartz may also be replaced by glass if clay is added to the batch to counteract the inferior spreading power which results when an enamel contains too much glass. The following mixtures are mentioned:—Ruby glass containing 10–12% of boric acid, 60 parts, clay 16 parts, cryolite 12 parts, and sodium carbonate 7 parts, for a white enamel. $1\frac{1}{2}$ parts of a melted mixture of glass 80 parts, and sodium carbonate, 40 parts, may be used to replace 1 part of borax and 1 part of quartz. Two parts of a frit made by melting glass 80 parts, sodium carbonate 40 parts, borax 30 parts, and clay 40 parts, may be used to replace 1 part of borax, 1 part of quartz, and $\frac{1}{2}$ part of felspar. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 4055 of 1875, 15,290 and 15,788 of 1886 and 17,878 of 1889.)

—A. B. S.

IX.—BUILDING MATERIALS.

PATENTS.

Cement and potassium compounds; Process of producing — C. Ellis, Montclair, N.J., Assignor to Ellis-Foster Co. U.S. Pat. 1,250,291, Dec. 18, 1917. Date of appl., Jan. 19, 1916.

FINELY divided, potassium-bearing, silicate rock is sprayed with sufficient alkaline-earth chloride solution to convert the whole of the potassium into chloride, and the mixture is caused to traverse an inclined, cylindrical chamber against a counter-current of flame and combustion gases, the bulk of the potassium being volatilised and recovered as chloride. The non-volatile residue is then mixed with suitable calcareous material to form a Portland cement raw mix, and the mixture heated to produce cement clinker. The volatilising point of the alkaline-earth chloride employed is materially above that of potassium chloride.—W. E. F. P.

Plaster or cement composition and method of making the same. Plaster composition. H. S. Thatcher, Assignor to Celite Products Co., Los Angeles, Cal. U.S. Pats. (A) 1,251,841 and (B) 1,251,842. Jan. 1, 1918. Dates of appl., June 17 and Aug. 8, 1916.

(A) CALCINED gypsum and porous, non-crystalline silica (uncalcined kieselguhr) are ground together to form an intimate mixture. (B) Calcined gypsum and uncalcined kieselguhr, both in a state of fine division, are mixed together in a dry condition.

W. E. F. P.

Cement; Manufacture of acid- and water-proof — C. C. Meigs, Assignor to Electro-Chemical Supply and Engineering Co., Philadelphia, Pa. U.S. Pat. 1,252,013, Jan. 1, 1918. Date of appl., Jan. 3, 1916.

In the manufacture of acid- and water-proof cement from silicious material and sodium silicate, the silicious material is first mixed with a chloride which, when the silicate is subsequently added, is acted upon by the water in the latter so as to liberate hydrochloric acid. The hardness and density of the cement are thereby increased.

—W. F. F.

Cement; Manufacture of building — A. H. Hambloch, Andernach, Germany, Assignor to H. F. Boersma, The Hague, Netherlands. U.S. Pat. 1,252,204, Jan. 1, 1918. Date of appl., Oct. 6, 1913.

SEE Fr. Pat. 449,642 of 1912; this J., 1913, 489.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron; A criterion for allotropic transformations of — at high temperatures. K. Honda. Sci. Rep. Tôhoku Imp. Univ., 1917, 6, 213–217.

THE physical properties of homogeneous substances change gradually with the temperature, while those of a substance undergoing an allotropic change vary more or less abruptly within the transformation range. At first sight, the difference between the two changes would seem to be one of degree, and hence, in an extreme case of discontinuous change, although the transformation is undoubtedly allotropic, if the change is gradual, its nature is difficult to decide. There is, however, one important difference, namely, that in non-allotropic changes the physical properties are a function of the temperature; whilst an allotropic transformation may, at a certain rate of heating, take place over an interval, yet if a suitable constant temperature be maintained, the transformation will take place at that temperature. An allotropic transformation may then be defined as a passage from one phase to another which takes place at a definite temperature if sufficient time is allowed for the transformation. In the case of pure iron, the changes A_3 and A_4 conform to this definition: A_3 takes place at 898°C ., the difference between A_3 and A_2 not exceeding 5° ; A_4 is more rapid than A_3 . A_2 proceeds over an interval of temperature, and is not an allotropic change. Carbon steels show two additional changes, A_0 at 215°C ., and A_1 at about $700^\circ\text{--}750^\circ\text{C}$. The latter is a phase-change, i.e., eutectic transformation of cementite and ferrite, while A_0 is of the same nature as A_2 , i.e., an internal change every stage of which is a function of the temperature.

—W. R. S.

Steel; Thermal expansion of — at high temperatures. K. Honda. Sci. Rep. Tôhoku Imp. Univ., 1917, 6, 203–212.

THE coefficient of expansion of carbon steels was found to be a function of the carbon content, apparent irregularities being due to manganese which, like carbon, reduces the coefficient. The following values are given for $15^\circ\text{--}75^\circ\text{C}$.:—Swedish iron (C 0.04%), 1.268×10^{-6} ; 0.75% carbon steel, 1.155×10^{-6} ; 1.50% carbon steel, 1.083×10^{-6} . The expansion at higher temperatures (to about 900°C .) is represented graphically, the curves showing hysteresis over the transformation range. The maximum contractions due to the A_1 and A_2 changes occurred in a 0.31% carbon steel. The coefficient of expansion increased rapidly with the temperature, but showed a slight decrease through the transformation range.

—W. R. S.

Steels; Thermal and electrical conductivities of carbon — at high temperatures. K. Honda and T. Simidu. Sci. Rep. Tôhoku Imp. Univ., 1917, 6, 219–233.

THE experiments were made with pure Swedish iron and carbon steels containing respectively 0.18, 0.44, 0.64, 0.80, 1.02, 1.30, and 1.50% C. The thermal conductivity decreased slowly at first, then somewhat rapidly, with increasing temperature. The electrical conductivity decreased at a gradually increasing rate up to the critical temperature, the curve being slightly convex with respect to the temperature axis. In the region A_1 the resistance increased abruptly during the range A_1 , and decreased during A_1 ; the difference between A_1 and A_2 was $50^\circ\text{--}60^\circ\text{C}$. The irregularity was greatest in 0.8% carbon steel. The product of thermal conductivity and electric resistance was fairly constant for the different specimens (Wiedemann-Franz's law),

but not proportional to the absolute temperature except for the pure Swedish iron and steel containing up to 0.44% carbon (Lorenz's law).

—W. R. S.

Iron and iron-nickel alloys; Cathodic deposits of — obtained at ordinary temperatures under high hydrogen pressure. Electrolytic deposition of alloys and their metallographic and mechanical investigation. VIII. R. Kremann and H. Breymesser. *Monatsh. Chem.*, 1917, 38, 359—384.

WHEN iron is deposited electrolytically under ordinary conditions it is charged with hydrogen and admixed with ferric oxide; it is brittle and hard. These conditions are due to the simultaneous liberation of hydrogen at the cathode. It is shown that elevation of the temperature, increase of the acidity or iron concentration of the bath, and increase of the current density accentuate these defects, but that if the electrolysis takes place in neutral solutions under a high pressure of hydrogen, the nature of the deposit is very much improved. To test these theoretical conclusions, a $N/1$ solution of ferrous sulphate was electrolysed by a current density of 0.25—0.75 amp. per sq. dm. under a pressure of 20 atmos. of hydrogen and the deposits compared with those obtained from solutions containing respectively citric acid and sulphuric acid, and electrolysed under 1 atm. pressure. The current efficiency at the higher pressure is 99.33—99.46%; the deposit contains less hydrogen, it is less brittle, composed of larger crystals, and is softer. It at once gives the equilibrium potential when immersed in $N/1$ ferrous sulphate solution. Similar experiments with mixed ferrous and nickel sulphate solutions gave nickel-iron alloys which did not show the improvement in the deposit shown in the case of iron. Photomicrographs of the deposits are given. (See also *J. Chem. Soc.*, March, 1918.)—J. F. S.

Copper; New method of determining —. J. Moir. *J. Chem. Met. Soc.*, S. Afr., 1917, 18, 133—135.

A WEIGHED quantity of the sample of copper or copper alloy is dissolved in strong nitric acid, and the solution shaken for 1 to 2 mins. to expel nitrogen peroxide, and then diluted to 20 c.c., treated with 0.5 grm. of urea, diluted to 50 c.c., and boiled for 15 secs. to remove all nitrous acid. The liquid, which is then no longer an oxidising agent, is nearly neutralised with sodium hydroxide, and treated with 2 to 3 grms. of sodium acetate, followed by a measured slight excess of standard sodium thiosulphate solution (3.904 grms. = 1 grm. of copper), and, immediately afterwards, by a sufficient excess (1.75 grms. per 1 grm. of copper) of potassium thiocyanate. The white precipitate of cuprous thiocyanate is filtered off by means of a filter of disintegrated paper pulp, roughly washed, and rejected. The filtrate is diluted to about 1 litre, treated with 5 to 10 c.c. of pure sulphuric acid, and the excess of thiosulphate titrated with $N/10$ iodine solution, with starch as indicator. It is essential that a large excess of thiosulphate should not be used, or the amount of copper found will be too high (102 to 105% for pure copper). None of the common metals, with the exception of iron, interferes with the reaction.—C. A. M.

Brass; Thermal expansion of α and β — between 0° and 600° C. in relation to the mechanical properties of heterogeneous brasses of the Muntz metal type. P. D. Merica and L. W. Schad. *J. Amer. Inst. Metals*, 1917, 11, 396—407.

IN an investigation into cases of fracture of 60 : 40 brass, it was ascertained that where failure could not be explained by known causes, the articles had been subjected at some time to a very rapid

cooling or quenching. Since such brass is heterogeneous, consisting of about equal proportions of α and β , it was thought that local stresses, due to unequal thermal contraction of the two constituents, might be developed by rapid cooling. By measuring the thermal expansion of sample ingots suitably heat-treated so as to produce homogeneous structure, it was observed that from 0° to about 300° C. the expansions of α and β -brass were almost equal; from 300° to 460° C. the expansion of β was almost twice that of α . Above the transformation temperature the expansion curve of β was almost linear and parallel to that of α . Hence the stresses during the cooling of 60 : 40 brass are greatest during the interval 500°—300° C. It may therefore be assumed that during slow cooling the constituents yield locally but when quenched they are in a state of stress at the ordinary temperature. The effect of quenching on the mechanical properties of test-pieces was not very apparent, except a lowering of the proportional limit by about 2000 lb. per sq. in.

—W. R. S.

Mercury still; Silica-glass —. J. C. Hostetter and R. B. Sosman. *J. Wash. Acad. Sci.*, 1918, 8, 11—15.

THE use of silica-glass for a vacuum still obviates the risk of breakage to which glass stills are liable when overheated. In the still shown in the

diagram the distillation chamber, D, and the condenser, C, are made of semi-transparent silica-glass, whilst the vertical tubes, A and B, are of transparent silica-glass. At V the still is connected with a suction pump, the joint being made with a hard cement, at a point where it will be cooled as completely as possible by the air. The resistance wire for heating the furnace is wound directly upon an alundum tube, and held in position by means of alundum cement. An

effective method of purifying the mercury is to shake it with cane sugar, and then to filter it through a pinhole in a filter paper.—C. A. M.

Colloidal gold and platinum; Precipitation of — on metallic surfaces. E. B. Spear and K. D. Kahn. J. Amer. Chem. Soc., 1918, 40, 181—184.

COLLOIDAL solutions of gold and platinum are coagulated when metal plates of various kinds are brought into contact with the solutions. The rate at which coagulation occurs increases with the electro-positive character of the metal. Plates of zinc, steel, nickel, lead, and copper decrease in activity in the order given. The effect depends also on the physical character of the surface, a rough surface being more active than a polished surface of the same metal. (See also J. Chem. Soc., March, 1918.)—H. M. D.

Amorphous metal hypothesis: The — and equi-cohesive temperatures. Z. Jeffries. J. Amer. Inst. Metals, 1917, 11, 300—323.

FINE-GRAINED metals are superior to coarse-grained in mechanical properties, and, up to the present, Beilby's amorphous cement theory accounts for this behaviour in the most satisfactory manner. At ordinary temperatures the amorphous metal cement is much harder than the crystalline phase, and, since the grain boundary surface increases as the grain size decreases, there will be more amorphous material in a fine-grained metal, hence greater cohesion. Additional amorphous metal is believed to be generated along the planes of slip and the grain boundaries during plastic deformation. According to the theory, the amorphous phase is more cohesive than the crystalline phase at ordinary temperature, but at high temperatures the reverse is the case. If so, there must be an intermediate temperature at which the cohesion of the amorphous and crystalline phases is the same: this is called the equi-cohesive temperature. Above this, the coarse-grained metal offers greater resistance to permanent deformation, and *vice versa*. The existence of the equi-cohesive temperature was proved by experiment. Fine wires of various metals were annealed in such a manner as to produce a fine-grained structure in one set, and a coarse-grained structure in another; the wires were examined microscopically to make certain that the desired grain size had been obtained. The resistance of the wires to bending was determined at different temperatures, by measuring the deformation caused by a 0.2 gm. rider. At low temperature the fine-grained wires proved stronger, and at high temperature weaker, than the coarse-grained; the equi-cohesive temperatures were found to be: iron, 550°—600° C.; tungsten, 1350° C.; silver, 250°—275° C.; gold, 275°—300° C.; platinum, 525°—550° C. These temperatures correspond closely with the recrystallisation or "equi-axing" temperatures of these metals after cold working.—W. R. S.

Temperature determinations by eutectic alloys. C. P. Steinmetz. J. Amer. Chem. Soc., 1918, 40, 96—100.

IN ORDER to measure the maximum temperatures existing locally at the rim of steel discs revolving at such speeds as to prevent the attachment of any temperature-measuring device, it has been proposed that small holes should be drilled into the rim of the rotating disc and that these should be filled with eutectic alloys melting at different temperatures. The alloys which melt will be ejected by centrifugal action and the required temperature may thus be approximately determined. In this connection, the melting points of some twelve eutectic alloys melting between 69.5° and 194° C. have been investigated. The following are the alloys with their respective

melting points:—Bi 15, Cd 3, Pb 8, Sn 4 (Wood's metal), 69.5°; Bi 7, Cd 1, Pb 6, 90.0° C.; Bi 2, Pb 1, Sn 1 (Rose metal), 93.5° C.; Bi 11, Cd 4, Sn 5, 102.4° C.; Bi 11, Pb 9, 132.0° C.; Bi 2, Sn 1, 132.5° C.; Bi 2, Cd 1, 143.5° C.; Cd 2, Pb 5, Sn 3 (cadmium-solder), 144.8° C.; Sn 4, Ti 3, 166.5° C.; Cd 1, Sn 2, 172.0° C.; Pb 3, Sn 5 (tin solder), 178.3° C.; Sn 10, Zn 1, 194.0° C. It is pointed out that the use of eutectic alloys affords a much closer scale of reference numbers than could possibly be attained by the use of pure metals. (See J. Chem. Soc., March, 1918.)—H. M. D.

PATENTS.

Cast iron and other metals; Flux for brazing — H. A. Gill, London. From J. H. Nathan, St. Kilda, Victoria, Australia. Eng. Pat. 112,500, Jan. 9, 1917. (Appl. No. 447 of 1917.)

A MIXTURE of sodium baborate 38% (by weight), washing soda 19%, sodium chloride 38%, soda ash 5%, with or without gold chloride 0.04%. —T. H. B.

Magnetic material [iron or iron alloys] for use in static transformers and other electrical apparatus. A. F. Berry, London. Eng. Pat. 112,649, Jan. 13, 1917. (Appl. No. 686 of 1917.)

MAGNETIC material (iron or an iron alloy) in sheet or strip form is coated, by suitable heating, with a thin, firmly adherent layer of iron oxide having high electrical resistance, and is then passed while in the heated condition, first through grooving rolls, to form longitudinal grooves extending nearly through the thickness of the sheet, with intervening parallel ribs of metal, then through flattening rolls to close the grooves to lock the oxide film and prevent subsequent detachment. The resulting sheet or strip has a greater electrical resistance in one direction than in another.—T. H. B.

[Steel] alloy. J. Churchward, Lakeville, Conn. U.S. Pat. 1,251,341, Dec. 25, 1917. Date of appl., Aug. 8, 1917.

A STEEL alloy contains Ni 1 to 5%, Cr 0.25 to 0.50%, and Mn 0.15 to 0.50%, together with titanium and "an element of the nature of molybdenum"; or Ni 1—3%, Mo 0.25 to 3%, Cr 0.25—1.5%, Ti trace to 0.50%, and Mn 0.15—0.50%. —T. H. B.

Iron or steel; Method of treating —. N. G. Petinot, Assignor to United States Alloys Corporation, New York. U.S. Pat. 1,252,023, Jan. 1, 1918. Date of appl., Mar. 7, 1917.

AN alloy of iron, titanium, and silicon is added to molten iron or steel. The alloy contains from 69 to 80% of iron, and the ratio of silicon to titanium is about 1 to 4, so that on oxidation a silicitanate of low melting point is produced.—W. E. F. P.

Metals; Devices for the pulverisation of molten or liquid —. A. Cusquel and H. Goupil, Levallois-Perret, France. Eng. Pats. (A) 106,095 and (B) 112,065, Apr. 24 and 30, 1917. (Appl. Nos. 5782 and 6111 of 1917.) Under Int. Conv., May 1, 1916.

(A) IN A pulveriser for powdering metals having a melting point below 800° C., e.g., tin, lead, antimony, zinc, and particularly aluminium, the molten metal is supplied to a tube having a nozzle controlled by a needle-valve, which is fitted at its rear end with a threaded portion and a stuffing-gland and is moved by an external turn-button. Air or gas under pressure is supplied to an annular chamber around the nozzle, having an annular outlet adjacent to the outlet for the metal. The annular chamber comprises a fixed rear plate, threaded on its periphery, and a nozzle screwing on to the plate so as to adjust the central outlet for the gas. In a modification, the nozzle may be

surrounded by an additional annular chamber, having a number of outlets in the front plate converging to a point on the axis of the jet and supplied with pressure gas, so as to draw the metallic powder away from the hot nozzle by suction. (B) In the apparatus first described in (A), a supplementary air chamber is provided at the rear of the adjustable annular air chamber, the common wall being perforated. The perforations have a total cross-section less than the section of the supply conduit, so as to minimise fluctuations of the air jet.—W. F. F.

Zinc alloys. E. Maas, Berlin. Eng. Pat. 112,487, Dec. 28, 1916. (Appl. No. 18,565 of 1916.)

ALLOYS consisting essentially of zinc, copper, and aluminium are made by first melting the copper, then adding aluminium in the amount required in the finished alloy, and allowing the mixture to cool to about 700°–800° C.; zinc, previously heated, is then added in the proportion of one-half of the amount required for the finished alloy, and the mixture allowed to cool to about 500° C., when the remainder of the zinc is added in a molten condition. For 100 parts of zinc, less than 4 parts of copper is employed, and the whole content of copper plus aluminium is between 7 and 8.5%.—T. H. B.

Copper; Electro-deposition of —. S. O. Cowper-Coles, Sunbury-on-Thames, Middlesex. Eng. Pat. 112,516, Jan. 18, 1917. (Appl. No. 935 of 1917.)

THE cathodes are mounted vertically in a vat and are caused simultaneously to rotate and to reciprocate in a vertical direction through a distance of several inches, one complete up-and-down displacement being effected while the cathode makes two or three revolutions. The peripheral speed of the cathode is about 50 ft. per minute. The electrolyte is caused to travel in a direction opposite, or at right angles, to that in which the cathode revolves, by squirting it through a number of jets or by blowing air through jets into the electrolyte.—T. H. B.

Melting furnaces. I. Hall, Birmingham. Eng. Pat. 112,559, Apr. 13, 1917. (Appl. No. 5216 of 1917.)

A MELTING furnace particularly suitable for melting aluminium and its alloys comprises a metallic melting pot supported at its upper part, a combustion chamber below the pot, and an injector box communicating tangentially with the combustion chamber. The casing enclosing the melting pot has a refractory lining following the contour of the pot. The whole is mounted on trunnions, so that it can be tilted. Over the melting pot is a cover, with or without external flues whereby the products of combustion can be conveyed into the chamber above the melting pot. A perforated plate, adapted to move vertically in the pot, is used for mixing purposes, to ensure homogeneity.—T. H. B.

Blast furnace bosh. W. J. Foster, Walsall, Staffs. Eng. Pat. 112,658, Jan. 17, 1917. (Appl. No. 844 of 1917.)

THE bosh is built up of bricks or blocks consisting of a mixture of carbonaceous material such as plumbago, or very finely ground hard coke, with Stourbridge or porcelain clay. The bosh walls are enclosed by a metal casing between which and the outer ends of the blocks a mixture similar to that composing the blocks is applied to form a sealing layer between the casing and the blocks, and also a key. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 13,690 of 1891 and 12,390 of 1912; this J., 1913, 794.)—T. H. B.

Volatile metallic values; Method of and apparatus for recovering —, in the form of metallic oxides, from molten slag. H. Witteborg, Caldwell, Idaho. U.S. Pat. 1,250,261, Dec. 18, 1917. Date of appl., Mar. 6, 1917.

THE molten slag, containing a suitable flux and reducing agent, is caused to flow in a comparatively shallow stream through a series of closed, superheating retorts while subjected to the action of blasts of flame and hot combustion gases. Means are provided for oxidising the metallic vapours produced and for collecting the resulting oxides.—W. E. F. P.

Flotation apparatus. W. E. Greenawalt, Denver, Colo. U.S. Pat. 1,250,303, Dec. 18, 1917. Date of appl., Dec. 4, 1915.

A TANK containing liquid has an outlet for tailings in its lower portion and a froth overflow at the top. A series of horizontal pipes is suspended in the tank, submerged in the liquid, the pipes extending transversely across the tank, and being surrounded by porous material. The ore is fed into the upper part of the tank and sinks through the liquid, and a gas is supplied to the pipes and escapes through the porous material into the liquid, the volume and pressure of the supply to the respective pipes being varied so as to produce a selective action on the ore from one end of the series of pipes to the other. The pipes are reciprocated transversely of their longitudinal axes and across the path of sinking particles.—T. H. B.

Ore-roaster; Blast —. G. H. Dern, Salt Lake City, and T. P. Holt, Silver City, Utah, Assignors to Holt-Christensen Process Co., Provo, Utah. U.S. Pat. 1,251,189, Dec. 25, 1917. Date of appl., Aug. 25, 1916.

A CHARGE holder supported by a built-up bin has a grate made up of independently movable sections; each section is composed of sub-sections adapted to operate in opposite directions, and each complete section can be operated independently of any other section. An air blast is led into the upper portion of the bin and upwards through the grate, and parts of the charge may be dropped into the bin for cooling purposes, remaining there without interference with the blast. A smoke-flue is supported transversely across the charge holder and ore is fed in on either side of the smoke-flue.—T. H. B.

Lead; Process of treating sulphide ores of —. R. De Luce, Oakland, Cal. U.S. Pat. 1,251,485, Jan. 1, 1918. Date of appl., May 8, 1917.

SULPHIDE ores of lead containing silver or copper are decomposed by a solution containing ferric chloride, and the residue is leached with an electrically conducting solution which is a solvent of lead chloride but is free from ferric chloride. The two solutions are electrolysed in the anode and cathode compartments respectively of an electrolytic cell having a porous diaphragm. Lead is deposited and the solutions regenerated for the decomposition and leaching of a fresh charge of ore.—W. F. F.

Solder. J. R. Kinder, jun., Ladd, Ill. U.S. Pat. 1,252,010, Jan. 1, 1918. Date of appl., May 31, 1917.

THE solder consists of lead 35.7%, pure zinc 24.5%, and tin 39.8%.—W. F. F.

Alloy; Dental —. H. K. Sandell, Assignor to H. S. Mills, Chicago, Ill. U.S. Pat. 1,252,038, Jan. 1, 1918. Date of appl., June 18, 1917.

NICKEL is added to molten tungsten and the resulting alloy incorporated with molten gold, the

proportion being 80 parts by weight of gold, 10 of tungsten, 7 of nickel, and a relatively small proportion of carbon.—T. H. B.

Metal reflectors, mirrors, and other metal articles having a reflecting surface or surfaces; Manufacture of —. T. Hancock, London. Eng. Pat. 112,884, May 16, 1917. (Appl. No. 6977 of 1917.)

Steel ingots; Casting —. H. H. Ashdown, Assignor to Sir W. G. Armstrong, Whitworth and Co., Newcastle-upon-Tyne. U.S. Pat. 1,251,951, Jan. 1, 1918. Date of appl., June 18, 1917.

SEE Eng. Pat. 105,617 of 1916; this J., 1917, 653.

Process for purifying clay and other silicious and aluminous earths and ores. Process for purifying aluminous ores, earths, clays, and sand. U.S. Pats. 1,251,957 and 1,251,958. See VIII.

XI.—ELECTRO-CHEMISTRY.

Lead standard cell and determination of the potential of the lead electrode. W. E. Henderson and G. Stegeman. J. Amer. Chem. Soc., 1918, 40, 84—89.

THE cell represented by Pb amalgam—PbSO₄—Na₂SO₄.10H₂O—Hg₂SO₄—Hg with an amalgam containing from 2.5 to 6% Pb gives a constant and reproducible electromotive force, which, for temperatures between 18° and 30° C., is given by the equation $E = 0.96463 + 0.000174(t - 25) + 0.00000038(t - 25)^2$. Like many other cells of this type, the E.M.F. shows a small gradual decrease over an extended period of time. (See also J. Chem. Soc., March, 1918.)—H. M. D.

Electrolysis of solutions of the rare earths. Dennis and Ray. See VII.

XII.—FATS; OILS; WAXES.

Fats; Saponification of —. II. J. P. Treuh. Proc. k. Akad. Wetensch. Amsterdam, 1918, 20, 343—357.

A STUDY of the hydrolysis of trilaurin by sulphuric acid confirms the theory that in the case of saponification in stages the relative concentration of glycerol at any moment is equal to the third power of the relative concentration of the free

fatty acid, provided that the ester groups are equivalent. (See also J. Chem. Soc., March, 1918.) —W. G.

Studies of drying oils. Properties of some cerium salts obtained from drying oils. Morrell. See XIII.

Formation of [lipolytic] ester-hydrolysing substances by the action of alkali on proteins. Hulton-Frankel. See XIXA.

PATENTS.

Fatty acids and their glycerides; Means for adding hydrogen to non-saturated —. A. Woltman, The Hague. Eng. Pat. 112,293, Dec. 29, 1916. (Appl. No. 18,621 of 1916.)

HYDROGEN under pressure is conducted through a perforated stirring device into the oil or fatty acid previously heated to the required temperature in presence of a catalyst. The agitator may be in the form of a horizontal hollow shaft arranged in an eccentric position and provided with hollow perforated arms, which revolve continuously in the liquid to be hydrogenated, while the outflow of gas may be in any direction relative to that in which the arms revolve.—C. A. M.

Hydrogenation [of oils]; Manufacture of catalysts for —. C. Ellis, Montclair, N.J. U.S. Pat. 1,251,201, Dec. 25, 1917. Date of appl., May 26, 1917.

A HYDROGENISING catalyst is obtained by heating the readily reducible soap (e.g., oleate) of a non-noble catalytic metal of atomic weight between 48 and 63.6 (e.g., nickel) in solution in an oil other than a drying oil, whereby the non-catalytic soap is decomposed and the catalyst liberated in a finely divided colloidal state in the oil.—A. DE W.

[Hydrogenation of oils;] Catalyser-concentrate [for —] and process of making same. C. Ellis, Montclair, N.J. U.S. Pat. 1,251,202, Dec. 25, 1917. Date of appl., Feb. 6, 1914.

A REDUCIBLE, oil-soluble, non-catalytic compound of a catalytic metal (e.g., nickel carbonyl) is incorporated in an oil not inimical to the activity of the catalyst, in a proportion materially in excess of that required to hydrogenise such oil, i.e., more than one part of nickel to 200 parts of oil. The compound is then reduced by heating at a sufficiently high temperature under superatmospheric pressure in presence of a reducing gas, whereby the catalyst is obtained in a colloidal state.

—A. DE W.

[Hydrogenation of oils;] Process of making a catalyst [for —]. C. Ellis, Montclair, N.J. U.S. Pat. 1,251,203, Dec. 25, 1917. Date of appl., Jan. 25, 1917.

A PURE fatty acid salt of a metal which in the free state possesses catalytic activity (e.g., nickel acetate) is reduced with a gas containing hydrogen.

—A. DE W.

[Hydrogenation of oils;] Process of making catalysts [for —]. C. Ellis, Montclair, N.J. U.S. Pat. 1,251,204, Dec. 25, 1917. Date of appl., May 1, 1917.

AN organic compound of a non-noble metal having an atomic weight between 51 and 63.6 (e.g., nickel) is heated out of contact with air (e.g., in a bath of oil) with an inorganic salt of the same metal containing nitrogen and oxygen.—A. DE W.

Oil [from garbage]; Percolators for use in extracting — by solvents. G. Harrison, London. From C. O. Bartlett and Snow Co., Cleveland, Ohio, U.S.A. Eng. Pat. 112,590, July 23, 1917. (Appl. No. 10,586 of 1917.)

OIL-CONTAINING material, and in particular garbage and similar refuse, is extracted with a solvent in

a drum which rotates on a horizontal axis, and is provided along a portion of its periphery with a perforated screen enclosing a space, which has valved outlet pipes and a steam or vapour discharge pipe connected with a conduit passing through the axis of the drum to a receiving chamber. To facilitate working, the manholes, the perforated strainer, and the openings of the pipes for the admission of steam, solvent, etc., are arranged on lines at distances about 90° apart on the circumference of the drum.—C. A. M.

Solidified plastic articles [soap]; Method of rapidly ageing—. De N. W. B. Young, Narberth, Pa., Assignor to Soap Works Equipment Co. U.S. Pat. 1,250,540, Dec. 18, 1917. Date of appl., Dec. 7, 1915.

A SOLIDIFIED plastic article having semi-crystalline, non-uniform surfaces, e.g., bar soap, is conveyed in a continuous and uninterrupted movement through a gaseous mixture so as partially to modify the surface, then through a static body of heated air of constant temperature to develop an "investing integument of jelly-like consistency," and finally through a cooling atmosphere to fix such integument, the resulting film being uniform, translucent, and "visibly free from crystalline salts."—A. DE W.

Fatty and other matters; Method for the recovery of—*from liquids*. T. W. Barber, London. U.S. Pat. 1,251,621, Jan. 1, 1918. Date of appl., Dec. 8, 1915.

SEE Eng. Pat. 23,741 of 1914; this J., 1915, 1061.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Drying oils; Studies of—. I. Properties of some cerium salts obtained from drying oils. R. S. Morrell. Chem. Soc. Trans., 1918, 113, 111—124.

CEROUS salts of the principal fatty acids in drying oils and of abietic acid were prepared by the interaction of a solution of a cerous salt and of a solution of the potassium salt of the respective acids. All these salts are colourless and insoluble in water. Cerous stearate, elaidate, β -elaeostearate, and palmitate are insoluble in ether, whilst cerous oleate, linolate, linolenate, α -elaeostearate, and abietate are soluble in ether and oil of turpentine. In each case the salt is of the normal type, CeX_3 . Ethereal solutions of the cerous salts of unsaturated fatty acids darken on exposure to the air, and in the case of the linolenate yield buff-coloured precipitates giving a peroxide reaction and having a composition corresponding with the formula of a basic ceric oxylinolenate $CeO(XO_2)_2$. The brown ethereal solution appears to contain a mixture of the salts CeX_3 and CeX_4 , or a basic salt, $2CeO(XO_2)_2$, formed by the oxidation of CeX_3 . After longer exposure of the solution to the air an insoluble salt of the type $CeO(XO_2)_2$ is produced. An ethereal solution of cerous oleate only darkens slightly on exposure, and becomes slightly turbid. Olive oil forms cerous salts of the normal type, CeX_3 , soluble in ether, and changing but slowly into the insoluble type, but after being heated in the absence of air it yields not only the normal salt, but also a soluble salt of the CeX_4 type and an insoluble basic ceric salt $CeOX_2$. Poppy-seed oil behaves in a similar way, whilst thickened linseed oil from which the polymerised compound has been extracted with acetone gives an increased yield (up to nearly 50%) of the basic ceric salt, $CeOX_2$. Raw linseed oil yields the normal salt, CeX_3 , and about 12.4% of the basic ceric salt. These

facts support the author's view (this J., 1915, 105) that there is a change in the intramolecular linkings prior to polymerisation when drying oils are polymerised by heat. Cerous α -elaeostearate from Chinese wood oil is readily soluble in ether, and yields an acid with the high m.pt. and high iodine value of α -elaeostearic acid, but after some time the salt becomes insoluble in ether, and then yields a mixture of a crystalline acid (m.pt. 45° to 46° C.) with iodine value 177.8, and a syrupy acid with lower iodine value, which liberates iodine from potassium iodide. These results show that partial oxidation of the cerous salt readily takes place, although the ethereal solution yields no precipitate when subjected to the action of a current of air or oxygen. The presence of mixed unoxidised and oxidised acids in the insoluble salt may be attributed to the formation of an insoluble basic ceric salt of the type Ce_2X_6O , and subsequent partial oxidation of the acid. The absence of any appreciable amount of β -elaeostearic acid shows that stereoisomeric change does not take place. The oxygen absorption of cerous α -elaeostearate, the initial stage of which takes more than 10 days, indicates that with the formation of a basic ceric α -elaeostearate of the type $Ce_2O(XO_2)_2$, from CeX_3 or Ce_2X_6O , one mol. of oxygen per mol. of acid is absorbed, so that the iodine value and iodine-liberation value become approximately equal. It is only after exposure of a year to oxygen that the second double linking of elaeostearic acid becomes peroxidised. The peroxidic acid shows gradual polymerisation until the syrupy liquid has set to a varnish. It is unstable with alkalis, but stable with acid, and is not reduced by zinc dust and acetic acid. The general conclusion drawn from these results is that the function of cerium α -elaeostearate as a drier may be represented by the following scheme:—
 CeX_3 or $Ce_2O(XO_2)_2 \rightarrow Ce_2(XO_2)_4$

This representation agrees with the conclusions of Ingie concerning lead linolenate (this J., 1917, 318). Cerium linoleate from linseed oil is a more active drier than lead linolenate, but is inferior to manganese and cobalt linoleates (Mackay and Ingie, this J., 1917, 318). The addition of a cerium drier to a varnish containing a lead drier does not accelerate the time of drying in the same way as does cobalt or manganese linoleate.—C.A.M.

Colophony; Colloidal nature of—. II. L. Paul. Kolloid-Zeits., 1917, 21, 148—154.

WHEN certain fractions of the distillate obtained by distilling mixtures of colophony with phenol, resorcinol, α - and β -naphthol are treated with diazo- or tetrazo-compounds, dyes are produced which are characterised by marked adhesive properties and may be fixed on the fibre without the use of mordants. The preliminary fractional distillation may be replaced by the treatment of the phenolic substance with a solution of a resin soap.—H. M. D.

PATENTS.

Iron pigment; Process of making—. A. F. Hoffman, Pittsburgh, Pa. U.S. Pat. 1,251,522, Jan. 1, 1918. Date of appl., Apr. 5, 1916.

NITRE cake and silicious material are heated together, whereby a soluble silicate is produced with evolution of sulphur trioxide and sulphuric acid vapours. A solution of ferrous sulphate is treated with this soluble silicate in such proportions that the reacting materials contain about one atom of iron to four atoms of silicon and that at least the major part of the iron is precipitated. The precipitate is separated, oxidised, and calcined till completely dehydrated.—A. DE W.

Rosin, turpentine, and oils [from wood]; Process of extracting — J. E. Teeple, Montclair, N.J. U.S. Pat. 1,252,058, Jan. 1, 1918. Date of appl., Jan. 12, 1914.

FINELY comminuted coniferous wood is heated to a temperature below 100° C. and subjected to the action of the mixed vapours obtained by passing steam into a bath of oil of turpentine. The vapours are condensed in such a way that the wood is exposed to the joint action of water and oil of turpentine at their boiling points until the resin and oils are sufficiently extracted. The amount of oil of turpentine used for extraction must be greater than the amount normally present in the wood.—A. DE W.

Titanium oxide paint and pigment and process of making same. L. E. Barton, Niagara Falls, N.Y., Assignor to The Titanium Alloy Manufacturing Co., New York. U.S. Pat. 1,251,170, Dec. 25, 1917. Date of appl., Mar. 25, 1916.

[Varnished] decorative surfaces; Treatment of — G. H. Hadfield, Mitcham, and A. E. Bawtree, Sutton, Assignors to Hadfields (Merton) Ltd., Mitcham. U.S. Pat. 1,252,001, Jan. 1, 1918. Date of appl., Sept. 18, 1917.

SEE Eng. Pat. 109,657 of 1916; this J., 1917, 1139.

Method of treating mine water containing sulphuric acid and iron salts [and obtaining a pigment]. U.S. Pat. 1,251,561. See XIXB.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

PATENTS.

Coagulating [rubber] latex; Process and apparatus for — Lintner & Co., Ltd., Amsterdam, Netherlands. Eng. Pat. 108,298, Oct. 27, 1916. (Appl. No. 15,342 of 1916.) Under Int. Conv., July 27, 1916.

LATEX treated with sulphur dioxide, either gaseous or in aqueous solution, is transferred to tanks, where it coagulates after the lapse of one hour or more according to the proportion of sulphur dioxide used. An apparatus is described for use with gaseous sulphur dioxide; the gas produced by burning sulphur in a stove is led into a vessel half filled with latex and fitted with a gauge glass. During the treatment with the gas the latex is allowed to flow from the vessel and at the same rate fresh latex enters from a tank, so that the process is continuous. The stream of treated latex flows into a suitable receptacle and is thence transported to the coagulation tanks. (Reference is directed in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 16,728 and 18,062 of 1913; this J., 1914, 758.)—D. F. T.

Rubber articles; Process of ornamenting — F. J. Croque, Cuyahoga Falls, Ohio. U.S. Pat. 1,251,182, Dec. 25, 1917. Date of appl., July 25, 1917.

THE surface of a rubber article is distorted or wrinkled whilst on its form by immersion in a rubber solvent; when the article is subsequently dipped in a colouring solution the swollen portions absorb more of the colour than do the portions which remain tight on the form.—D. F. T.

Rubber substitute and process of making the same. W. W. Carter, Needham, Mass. U.S. Pats. (A) 1,251,862 and (B) 1,251,863, Jan. 1, 1918. Dates of appl., Mar. 29 and 30, 1917.

(A) A RUBBER substitute is prepared by mixing a sulphonate and a polymerisable oil together

with a substance adapted to neutralise any free acid, this substance being provided with a protective coating. The sulphonate and polymerisable oil give rise to a gelatinous product, and the protective coating on the neutralising substance prevents this from exerting its influence until after the completion of the main reaction. (B) The reaction product of a polymerisable oil, such as Chinese wood oil, with sulphonates derived from tar acids, is submitted to the action of formaldehyde or some equivalent substance; it is then washed and dried.—D. F. T.

XV.—LEATHER; BONE; HORN; GLUE.

Gelatin; Swelling of — in polybasic acids and their salts. M. H. Fischer and M. O. Illoker. J. Amer. Chem. Soc. 1918, 40, 272—292.

THE absorption of water by gelatin was determined in different concentrations of the primary, binary, and ternary salts of phosphoric, citric, and carbonic acids, and in solutions varying from pure acid to pure alkali (sodium hydroxide) for the same three acids. The absorption is greatest in pure acids and alkali, decreasing considerably in the presence of salts, and with certain salts at high concentrations, it is less than in pure water. From a certain minimum there is a progressive increase in the absorption with increase of the acid or alkali content of the mixture. (See also J. Chem. Soc., March, 1918.)—L. A. C.

Fibrin; Swelling of — in polybasic acids and their salts. M. H. Fischer and M. Berzinger. J. Amer. Chem. Soc., 1918, 40, 292—303.

EXPERIMENTS in the absorption of water by fibrin in acid and alkaline solutions containing the acid salts (using phosphoric and citric acids) gave essentially the same results as when gelatin was used (see preceding abstract), with the exception that the points of minimum absorption corresponded to a different acid content in the solution. (See also J. Chem. Soc., March, 1918.)—L. A. C.

Gelatin; Liquefaction or "solution" of — in polybasic acids and their salts. M. H. Fischer and W. D. Coffman. J. Amer. Chem. Soc., 1918, 40, 303—312.

EXPERIMENTS showed that there is a progressive increase in the tendency of gelatin to dissolve in mixtures of the salts of polybasic acids as the amount of acid or alkali in these mixtures is increased from a given low point. This shows that hydration and "solution" of a protein are not the same thing; if they were, the addition of an acid or alkali to a solution should cause it to gel, for this causes increased hydration (see preceding abstracts). (See also J. Chem. Soc., March, 1918.)—L. A. C.

Fibrin; Swelling of — in acids. I. Colloidal behaviour; The molecular mechanism of —. R. C. Tolman and A. E. Stearn. J. Amer. Chem. Soc., 1918, 40, 261—271.

EXPERIMENTS were performed to determine the swelling of fibrin in various solutions of acids and salts and the adsorption of acids from the solutions by the fibrin, with a view to investigating the molecular mechanism by which such swellings and reductions in swellings are brought about. The main points in the theory advanced, which is in accordance with the results obtained, are: Colloids have a marked tendency to adsorb hydrogen ions from acid solutions and hydroxyl ions from alkaline solutions. In an acid solution, the adsorbed hydrogen ions, together with a corresponding number of anions, form a "double layer" on the walls of the pockets in the interior

of the gel and this leads to swelling and imbibition of water by electrostatic repulsion. The addition of a strong electrolyte furnishes ions in the interior of the pockets which will tend to arrange themselves so as to neutralise the electric fields of the adsorbed layers, bringing about a reduction of the swelling. The addition of a neutral salt to an acid solution tends to neutralise the electric field of the adsorbed acid, and hence makes it easier for more acid to get to the surface of the pockets, leading to increased adsorption. Salts with multivalent ions are more effective in reducing swelling than salts with univalent ions, a divalent ion taking up no more room than a univalent ion, but being twice as effective in neutralising the electric field. (See also J. Chem. Soc., March, 1918.)—L. A. C.

PATENTS.

Bichromates [from spent tanning liquors]: Process for reclamation of —. C. W. Tucker, North Andover, Mass., and T. A. Kelley, Lynn, Mass. Eng. Pat. 105,222, Jan. 25, 1917. (Appl. No. 1291 of 1917.) Under Int. Conv., Mar. 25, 1916.

SODIUM or potassium bichromate is reclaimed from spent chrome tanning liquors by mechanically removing foreign matters in suspension, e.g., by means of aluminium hydroxide, and evaporating to remove the less soluble and deleterious salts whilst retaining the chromates in solution. An alkali carbonate may be used to precipitate the alkaline earths before evaporating the solution.

—F. W. A.

Glue [from starch]: Process of making —. F. G. Perkins, Lonsdale, Pa., Assignor to Perkins Glue Co. U.S. Pat. 1,251,275, Dec. 25, 1917. Date of appl., Dec. 26, 1913.

JOINER'S glue is made by stirring starch, water, and "solvent" in a water-jacketed vessel. Steam is injected into the water in the jacket so as to heat the mixture to a temperature below that of the bursting point of the starch, and the heating is checked subsequently so as to prevent overcooking of the glue after it has been dissolved.

—A. B. S.

XVI.—SOILS ; FERTILISERS.

Soil; Absorption of cations and anions by —. A. De Dominicis, G. Mammanno, and L. Diaferia. Annali della Regia Scuola Supr. di Agric. Portici, 1916, 13, 26. Bull. Agric. Intell., 1917, 8, 1964.

FIVE different soils were used: chlorides of ammonium, potassium, sodium, calcium, magnesium, aluminium, and trivalent iron were tested for the absorption of the cations, and, for the absorption of the anions, chloride, nitrate, nitrite, sulphate, carbonate, silicate, monohydrogen phosphate, and aluminate of sodium were used. The results show that soil absorbs the cations without exception, those most largely absorbed being iron and aluminium. The anions were also absorbed without exception, the absorption in some cases equalling, and even exceeding, that of the cations, though with certain soils the chloride and nitrate ion showed a negative absorption. The anions are absorbed by amorphous compounds charged with positive electricity and the cations by amorphous compounds charged with negative electricity. Both in the case of the anions and the cations the univalent ions are less absorbed than the divalent and these in turn less than the trivalent ions. The results show that, in the absorbent capacity of the soil, the physical character is the decisive factor.—W. G.

Soil acidity and the hydrolytic ratio in soils. C. H. Spurway. J. Agric. Res., 1917, 11, 659—672.

A NUMBER of acid and alkaline soils from glacial formations were examined and a definite relationship was found between the ratio of calcium to iron and aluminium soluble in N/5 hydrochloric acid, and the soil reaction. All acid soils have ratios $\text{CaO} : (\text{Fe}_2\text{O}_3 + \text{Al}_2\text{O}_3)$ above 1:1.3 and all the alkaline soils have ratios below this figure. The lime requirement of such acid soils may be computed by calculating the amounts of calcium oxide necessary to add to the soil to bring this ratio to 1:1.3. The results so obtained agree closely with those from the indirect titration method. An indirect titration method is described in which certain fixed quantities of a standardised calcium hydroxide solution are allowed to react separately with varying amounts of soil. The concentrations of soil and solution giving a neutral reaction are determined either by electrical resistance measurements or by the colour reaction with phenolphthalein. (See also J. Chem. Soc., March, 1918.)—W. G.

Basic slag and rock phosphates: Trials on grass land with open-hearth —. G. S. Robertson. J. Bd. Agric., 1918, 24, 1077—1086.

THE results are given for the first two years of a six years' comparative field test of the relative value of low and high citric-soluble phosphates when applied to grass land. A high-grade basic slag, Gafsa rock phosphate, open-hearth basic slag (fluorspar slag, 45% citric-solubility), and two low-grade, high citric-soluble slags were compared on three clay soils. On all three soils the fluorspar slag gave very satisfactory results. On only one soil did the high citric-soluble slag give results appreciably superior to the low citric-soluble phosphate. The author advocates that, as far as possible, open-hearth basic slag should be utilised for improving poor pasture and meadow hay land. Fineness of grinding is essential.—W. G.

Phosphates; Conversion of insoluble into "soluble" —. A. M. Johnston. J. Chem., Met., Min. Soc., S. Afr., 1917, 18, 140—141.

A SAMPLE of Saldanha Bay phosphate contained 20.6% of total and 0.4% of "soluble" phosphoric anhydride. On fusing a finely powdered mixture of 25 grms. of the sample with 15 grms. of calcium carbonate for 1½ hours at 1100° C. the resulting mass (29 grms.) contained 17.2% of total and 6.4% of "soluble" phosphoric anhydride. A mixture of 25 grms. of the sample, 17½ grms. of sodium bisulphate, and 1½ grms. of powdered coke was finely pulverised and heated in a crucible for about an hour at 1100° C. (see Hall's "Fertilisers and Manures," p. 135). The friable mass (36 grms.) was powdered, and treated with three successive portions of about 200 c.c. of water. The dried insoluble portion (34 grms.) contained 13.8% of total and 12.1% of "soluble" phosphoric anhydride, the "soluble" phosphate being determined by agitating 2 grms. of the material for 30 mins. with 200 c.c. of 2% citric acid solution. The total phosphate left in the mass after washing with water represented 91% of the "soluble" phosphate and 81.8% of the total phosphate in the mineral. On a large scale the conversion would be best effected by the use of a reverberatory pan furnace, or by converting the mixture into briquettes, with or without the addition of molasses, and burning it in an oven.—C. A. M.

Germination: Influence of metallic salts on — in the presence of calcium. L. Maquenne and E. Demoussy. Comptes rend., 1918, 166, 89—92.

THE chlorides of sodium, potassium, strontium, barium, manganese, and lead, and the sulphates of ammonium, magnesium, zinc, and copper,

function as antagonists to calcium in germination, in the same way as calcium behaves as anti-toxic to them. (See also J. Chem. Soc., March, 1918.)

—W. G.

PATENTS.

Phosphate material; Process of treating—. H. Blumenberg, jun., Assignor to C. Allen, Los Angeles, Cal. U.S. Pat. 1,251,742, Jan. 1, 1918. Date of appl., June 21, 1917.

Finely powdered rock phosphate is intimately mixed with an ammonium salt and heated to form ammonium phosphate. Claim is also made for a fertilizer comprising powdered rock phosphate and ammonium sulphate.—W. G.

Acid calcium phosphates [superphosphate]; Process of making—. H. Blumenberg, jun., Assignor to C. Allen, Los Angeles, Cal. U.S. Pat. 1,252,318, Jan. 1, 1918. Date of appl., June 7, 1917.

CALCAREOUS phosphate material or phosphate rock is treated with ammonium carbonate or with ammonia and carbon dioxide in the presence of water, calcium carbonate and ammonium phosphate being formed. The ammonium phosphate is separated from the mixture and heated to drive off ammonia and leave phosphoric acid, with which is mixed powdered phosphate material in proportion to produce acid calcium phosphate.

—W. G.

Bacterial product [fertiliser] and process of preparing same. G. H. Earp-Thomas, Glen Ridge, N.J. U.S. Pat. 1,252,332, Jan. 1, 1918. Date of appl., Mar. 30, 1917.

The product consists of granules of humus inoculated with bacteria beneficial to soil, e.g., nitrobacteria, and coated with a protective substance, the adherent coating being superficially treated to prevent the granules from sticking together. An acid or basic mineral fertiliser may be mixed with the coated particles.—W. G.

Fertilisers. J. G. Lipman, New Brunswick, N.J., U.S.A. Eng. Pat. 104,171, Feb. 7, 1917. (Appl. No. 1881 of 1917.) Under Int. Conv., Feb. 17, 1916.

SEE U.S. Pat. 1,222,112 of 1917; this J., 1917, 560.

XVII.—SUGARS; STARCHES; GUMS.

Sugars; Auto-oxidation of—. L. Berczeller and E. Szego. Biochem. Zeits., 1917, 84, 1—36.

METHYLENE-BLUE and some other substances promote the oxidation of sugar when shaken in alkaline solution with air. Charcoal was found to promote oxidation by alkaline copper solutions. (See also J. Chem. Soc., March, 1918.)—S. B. S.

Monosaccharides; Influence of different compounds on the destruction of—by sodium hydroxide and on the inversion of sucrose by hydrochloric acid. H. I. Waterman. Proc. K. Akad. Wetensch. Amsterdam, 1918, 20, 382—391.

AMINO-ACIDS retard on the one hand the destructive action of sodium hydroxide on dextrose, and on the other hand the inversion of sucrose by hydrochloric acid. Amines are without influence on the destruction of dextrose by alkali but retard the inversion of sucrose by acid. (See also J. Chem. Soc., March, 1918.)—W. G.

Lactose. A. Snits and J. Gillis. Proc. K. Akad. Wetensch. Amsterdam, 1918, 20, 520—532.

A DISCUSSION of the relationship between the α - and β -anhydrous forms and the hydrate of lactose. (See also J. Chem. Soc., March, 1918.)

—W. G.

Adsorption compounds and adsorption. I. The starch-iodine complex. L. Berczeller. Biochem. Zeits., 1917, 84, 106—117.

THE presence of potassium iodide is not necessary for formation of the complex. Starch takes up more iodine at lower than at higher temperatures, and the adsorption equilibrium is attained more rapidly in dilute than in concentrated solution. (See also J. Chem. Soc., March, 1918.)—S. B. S.

Dextrins; Analysis of commercial—. M. C. Lamb and A. Harvey. J. Soc. Dyers and Col., 1918, 34, 10—11.

THE following determinations are carried out: **Moisture**. 5—6 grms. is dried at 100° C. in an air-oven for 4 hrs. **Ash**. The residue from the preceding determination is incinerated at as low a temperature as possible. **Water-soluble matter**. 10 grms. is shaken with cold water, allowed to stand overnight, an aliquot portion of the filtrate evaporated, and the residue dried. **Reducing sugar**. Determined in a portion of filtrate from preceding estimation, using Fehling's solution and calculating to dextrose (maltose is only present in dextrins manufactured by a diastase process, a method not frequently used commercially). **Starch**. Free starch is tested for by the iodine reaction in the portion insoluble in cold water. The results of a number of analyses show that dextrins are liable to considerable variation in composition, and the following analytical standards for commercial dextrins are suggested: Moisture, 8—10%; ash, 0.1—0.3%; water-soluble matter, 75—85%; dextrose, up to 8%. After allowing for any dextrose and soluble ash, the water-soluble matter may be taken to represent the dextrin. The sample should give a neutral reaction. The darker coloured samples contain the highest proportion of water-soluble matter; very dark samples frequently contain a high proportion of dextrose; buff-coloured dextrins are preferable to white samples, as they are not so likely to contain a large quantity of unconverted starch.—F. W. A.

PATENTS.

Decolorising agents [charcoal]; Process of making—[from molasses] and the products thereof. H. L. Lyon and S. S. Peck, Honolulu, Hawaii. U.S. Pat. 1,251,546, Jan. 1, 1918. Date of appl., Sept. 20, 1915. Renewed May 26, 1917.

A DECOLORISING material is produced by treating molasses with sulphuric acid until charring takes place and removing the soluble substances. Whenever activity diminishes, the treatment with sulphuric acid may be repeated. A "body-giving agent" may be coated or impregnated with the carbon.—L. A. C.

Process of making glue [from starch]. U.S. Pat. 1,251,275. See XV.

XVIII.—FERMENTATION INDUSTRIES.

Starch; Precipitation of—by diastase. L. Berczeller. Biochem. Zeits., 1917, 84, 37—41.

THE amount of starch precipitated when its solutions are treated with diastase depends on the previous treatment of the solutions. The author ascribes the action to the aggregation of colloidal particles. Diastatic action diminishes the viscosity and thus promotes precipitation of the larger particles as they are formed. (See also J. Chem. Soc., March, 1918.)—S. B. S.

Diastases; Action of oxidising and reducing substances on—. L. Berczeller and E. Fodor. Biochem. Zeits., 1917, 84, 42—49.

DILUTE permanganate, iodine, and hydrogen peroxide solutions inhibit the action of diastase.

The slight acceleration by formalin is due to the presence of formic acid. (See also J. Chem. Soc., March, 1918.)—S. B. S.

Enzymes: Periodic phenomena in the action of — as a result of their colloidal nature. J. T. Groll. Kolloid-Zeits., 1917, 21, 138—148.

PERIODIC variations in the activity of urease, extracted from soya beans, have been observed in experiments, in which the activity was measured from day to day by Van Slyke's method. The enzyme preparations were kept at constant temperature varying from 35° to 65° C. The periodicity is no longer apparent at the last-mentioned temperature and the activity then decreases continuously. The observations seem to show that the decomposition of the enzyme which follows a normal course at 65° C. is complicated at lower temperatures by a periodic change which is supposed to be connected with the colloidal nature of the enzyme. Other enzymes, for example lipase, appear to show the same phenomenon, and as the result of the investigation of colloidal metals with respect to their catalytic activity towards hydrogen peroxide, it is said that these inorganic enzymes show similar effects under certain conditions. To explain the periodicity it is suggested that the colloids are subjected to periodic changes in respect of their degree of dispersity.—H. M. D.

Water-soluble accessory growth-promoting substance in yeast. Drummond. See XIXa.

Formation of [lipolytic] ester-hydrolysing substances by the action of alkali on proteins. Hulton-Frankel. See XIXa.

XIXa.—FOODS.

Flour: Soluble nitrogenous substances as an index of the baking value of — E. Rousseaux and M. Sirot. Comptes rend., 1918, 166, 190—192.

THE most favourable proportion of soluble nitrogen with respect to total nitrogen in flour is about 16—17%. Flours with this proportion of soluble nitrogen absorb water well and the dough has a good plasticity. If the proportion of soluble nitrogen rises or falls too much the flour is likely to show bad baking qualities. If the total nitrogen rises too much the flour is worked with great difficulty.—W. G.

Milk: Proteins of cow's —. T. B. Osborne, A. J. Wakeman, C. S. Leavenworth, and O. L. Nolan. J. Biol. Chem., 1918, 33, 7—17.

WHEN precipitated lactoglobulin containing 2.2% of phosphorus is digested with alcohol, a phosphatide appears to be split off and the remaining coagulated lactoglobulin contains only 0.24% of phosphorus. A similar cleavage of phosphatide occurs in the case of vitellin, and the authors suggest that these so-called globulins are really lecithalbumins or mixtures of proteins. Lactalbumin is practically free from phosphorus. Although traces of proteoses can always be isolated from cow's milk, it is uncertain whether these substances are present as such in the fresh milk or are formed from the proteins by the reagents employed for their isolation. Siegfried's "nucleon" (Z. physiol. Chem., 1895-6, 21, 360) is probably a mixture of uncoagulable protein and a still unidentified organic substance which yields phosphoric acid on hydrolysis. By extraction of precipitated caseinogen with alcohol, a new protein is obtained which resembles the gliadin of wheat in its solubility in 50%—70% alcohol. (See also J. Chem. Soc., March, 1918.)—H. W. B.

Milk: Adenine and guanine in cow's —. C. Vogtlin and C. P. Sherwin. J. Biol. Chem., 1918, 33, 145—149.

Cow's milk contains 5 mgrms. of adenine and 10 mgrms. of guanine per litre. These values may be considered as minimum values, because the method of isolation of these aminopurines is not quantitative.—H. W. B.

Lactic organisms: Proteolytic activity of —. III. and IV. C. Gorini. Atti R. Accad. Lincei, 1917, [V], 26, ii, 195—199, 223—227.

IN investigations on the proteolytic and coagulating actions of lactic acid bacteria on milk, it is essential that the latter be not sterilised by heating too long or at too high a temperature, since otherwise it is not readily acted on by the enzymes of the micro-organisms. The sterilisation should modify as little as possible the original white colour of the milk and is best effected in steam at the ordinary pressure for 15—20 minutes on each of three successive days; before use the milk should be tested to ascertain if it is free from bacteria.

—T. H. P.

Dietary-essential, water-soluble B; Study of the — in relation to its solubility and stability towards reagents. E. V. McCollum and N. Simmonds. J. Biol. Chem., 1918, 33, 55—89.

THE authors describe experiments designed to reveal a method for the isolation of the food accessory substance, termed "water-soluble B," the lack of which leads to the development of polyneuritis. Polyneuritis can be produced in rats by feeding on a diet which is complete in all respects except in content of water-soluble B. Extracts of a material rich in water-soluble B, which had been prepared in various ways, were administered to rats before and after the onset of polyneuritis, and the results clearly indicated that water-soluble B is not extracted directly from beans, wheat germ, or pig's kidney by ether, benzene, or acetone, but is readily extracted by alcohol, and that after being removed by alcohol and deposited on an inert material, such as dextrin, it is then soluble in benzene and slightly soluble in acetone.—H. W. B.

Yeast: Water-soluble accessory growth promoting substance in —. J. C. Drummond. Biochem. J., 1917, 11, 255—271.

EXPERIMENTS were made with young rats fed on a basal diet free from water-soluble accessory foodstuff, so that growth was inhibited. Addition of small quantities of dried yeast or of yeast extract ("Marmite") to the diet caused a resumption of normal growth (cp. Seidell, this J., 1917, 562). Dried yeast retained this stimulating power practically unimpaired after extraction with ether or absolute alcohol, though 70% alcohol appeared to remove some of the active substance. A loss of activity followed dialysis of the yeast extract, i.e., the accessory factor passed through the septum. Heating of the yeast or juice for 30 mins. at 100° C. had no effect, but heating at 120° C. in an autoclave caused a partial loss of stimulating power. The activity of the yeast extract was scarcely weakened by boiling with 1% of hydrochloric acid or by the prolonged action of 5% sodium hydroxide at ordinary temperatures. Commercial meat extract ("Lemco") was found to be destitute of the water-soluble accessory growth-promoting factor. The repeated failures to isolate substances of this class in the pure condition are attributed more to the fact that they are readily removed from solution by precipitates, than to their reputed instability. (See also J. Chem. Soc., March, 1918.)—J. H. L.

Kafirin: Nutritive properties of—A. G. Hogan. J. Biol. Chem., 1918, 33, 151—159.

KAFIRIN (see this J., 1917, 158) is the chief protein in kafir, one of the sorghum grains of America. It is deficient in lysine and cystine, and rats fed on a diet in which kafirin is the only protein do not grow, unless lysine is also added. The subsequent addition of cystine slightly increases the rate of growth.—H. W. B.

Ester-hydrolysing substances; Formation of [lipolytic]—by the action of alkali on proteins. F. Hulten-Frankel. J. Biol. Chem., 1917, 32, 395—407.

FALK (this J., 1917, 974) has shown that some proteins when treated with alkali acquire ester-hydrolysing properties. Experiments with alkali of different concentrations showed that in the case of casein, gelatin, and egg albumin, the greatest ester-hydrolysing activity is produced by the action of 3*N* alkali. The solutions are all most active at a hydrogen ion concentration less than 10^{-7} , i.e., when the reaction is slightly alkaline. The activity of the solutions is not much affected by the duration of the action of alkali on the protein nor by the temperature at which such action takes place, except when the temperature is unduly high (80° C.). The solutions are not rendered inactive by boiling and their action on different esters shows marked differences. Falk (*loc. cit.*) has suggested that the ester-hydrolysing activity of the hydrolysed proteins is due to the presence of an enol-lactin structure, and the differences in activity may be due to the presence of different groupings attached to the sides of the enol-lactin linkage. The following proteins when acted upon by alkali showed ester-hydrolysing properties: casein, gelatin, egg albumin, castor bean globulin, zein, phaseolin, edestin, ovitellin, egg globulin, pseudoglobulin, englobulin, soya bean globulin and glutelin, gliadin, and lactalbumin. Solutions obtained by hydrolysing protein with acid do not exhibit ester-hydrolysing properties

Hæmoglobin [in blood]; Colorimetric estimation of—W. W. Palmer. J. Biol. Chem., 1918, 33, 119—126.

THE blood is diluted with a hundred volumes of 0.4% ammonia and is then saturated with carbon monoxide. It is compared in a Duboscq colorimeter with a standard carbon monoxide hæmoglobin solution prepared from blood of known oxygen capacity. The accuracy of the estimation is usually within 1%. (See also J. Chem. Soc., March, 1918.)—H. W. B.

PATENTS.

Antiseptic or sterilising agents for use in the preservative treatment of meat. A. E. Sherman, London. Eng. Pat. 112,473, Oct. 5, 1916. (Appl. No. 14,138 of 1916.)

BEFORE being chilled for cold storage treatment, meat is exposed to an atmosphere containing an antiseptic gas which is obtained by vaporising stearoptene, $C_{10}H_{16}O$, derived from *Carum copticum*, *Thymus vulgaris*, *Monarda punctata*, or similar herbs. A still more active agent is obtained by vaporising a chlorinated or saline solution containing a stearoptene of the above-mentioned formula. By this means the freshness and the "bloom" of the meat are retained during the cold storage treatment. The stearoptene may

be incorporated, with a binding agent, and made into tablets graduated in size so as to yield a sufficient quantity of antiseptic gas for a chamber of given capacity.—C. A. M.

Coffee extract. L. Etaix, Paris. U.S. Pat. 1,251,359, Dec. 25, 1917. Date of appl. Feb. 25, 1915.

SEE Eng. Pat. 2722 of 1915; this J., 1915, 1268.

Apparatus for cooling and drying compressed materials and substances, seeds and the like and for removing dust therefrom. Eng. Pat. 112,512. See I.

Method of preservation. U.S. Pat. 1,252,090. See XIXB.

XIXB.—WATER PURIFICATION; SANITATION.

Water; Identification and determination of lead in—R. Meldrum. Chem. News, 1918, 117, 49—50.

ONE hundred c.c. of the sample is treated with 1 c.c. of 20% acetic acid, and, after 2 mins., 1 c.c. of saturated hydrogen sulphide solution is added. The coloration obtained, if any, is compared with that given by a known amount of lead under the same conditions. In preparing this comparison solution, the same water as the sample, but free from lead, must be used, since the intensity of the lead sulphide coloration is largely influenced by the saline constituents, etc., of the water. Copper, if present, is detected by means of ammonia, and in this case the lead must be identified and estimated by the bichromate method. (See also J. Chem. Soc., March, 1918.)—W. P. S.

Alkalis in drinking water; Determination of—M. Wagenaar. Pharm. Weekblad, 1917, 54, 1454—1455.

THE method of Fresenius involving the separation of the alkali metals is too tedious, and in the indirect method the errors of analysis accumulate in the result (compare Pharm. Weekblad, 1917, 1115). The abbreviated method described by the author (Pharm. Weekblad, 1916, 233) is preferable. After freeing the total solids from silica, iron, and alumina, calcium is precipitated as oxalate and weighed as CaO , the residue is evaporated with several drops of sulphuric acid, and the ignited residue of alkali sulphates and magnesium sulphate weighed; the magnesium content is then determined. Kolthoff has endeavoured further to simplify the method by using the insolubility of calcium sulphate in 50% alcohol, in which the alkali sulphates and magnesium sulphate dissolve; it was found difficult to extract the calcium sulphate satisfactorily, and errors are introduced in calculating the percentage of alkali. As the potassium content is calculated as sodium, it is recommended that the "atomic weight" of the alkali metal be taken as 24 instead of 23.—F. W. A.

Dichloramine T; Solvents for—H. D. Dakin and Dunham. Brit. Med. J., Jan. 12, 1918. Pharm. J., 1918, 100, S2.

CHLORINATED paraffin wax ("chlorcosane") is the most satisfactory solvent for dichloramine T, solutions of 8.5 to 10% strength being obtainable. The solvent is prepared by passing chlorine into paraffin wax, of m. pt. 50° C. or higher, at 120° C., until an increase in weight of 45 to 55% is attained.

Case of poisoning by hydrofluosilicic acid and detection of this acid in animal organs. Spaeth. See VII.

Colorimetric estimation of hæmoglobin [in blood].
Palmer. See XIXA.

PATENTS.

Water; Filtration of —. F. P. Candy, Cheam, Surrey. Eng. Pat. 112,672, Jan. 22, 1917. (Appl. No. 1061 of 1917.)

IN a mechanical gravity filter of the type in which the water passes at a high speed through an open filter provided with means for cleaning the filtering medium by a reverse flow of water, the water to be filtered is delivered into a measuring tank above the filter from which it flows by slotted weirs into the filter. A float in a chamber in the measuring tank is connected by a flexible cord to a dial indicator which shows the volume of water passing over the weirs. The filter is maintained full of water by a regulating valve placed on the outlet pipe for the filtered water and connected with a float on the water at the top of the filter. The valve also regulates the rate of outflow according to the level of the water above the filtering material, and at its extreme positions the float brings an alarm bell into action. Rapidity of filtration is effected by connecting the outflow pipe to a suction pump.—J. H. J.

Water containing sulphuric acid and iron salts; Method of treating — [and obtaining a pigment]. W. M. Parkin. Pittsburgh, Pa. U.S. Pat. 1,251,564, Jan. 1, 1918. Date of appl., Apr. 5, 1916.

MINE waters containing iron salts and free acid are treated by adding pulverised limestone in sufficient quantity to neutralise the acid and to precipitate the greater part of the iron. The precipitate is separated and heated to 179°–338° C., whereby it is converted into a finely divided pigment without undergoing any grinding operation.—J. H. J.

Preservation; Method of —. W. R. Clayton, Evanston, Ill. U.S. Pat. 1,252,090, Jan. 1, 1918. Date of appl., Dec. 2, 1915.

THE substance to be preserved is first partially desiccated and is then placed in a closed chamber in the presence of calcined gypsum. A circulation of heated air is kept up in the chamber.—J. H. J.

Water; Method and apparatus for obtaining pure — from salt water. F. T. Evans, Newport, R.I., U.S.A. Eng. Pat. 112,679, Jan. 25, 1917. (Appl. No. 1291 of 1917.)

Perculators for use in extracting oil [from garbage] by solvents. Eng. Pat. 112,599. See XII.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Orimes; New method of dehydration of — by catalysis. A. Mailhe and F. de Godon. Bull. Soc. Chim., 1918, 23, 18–20.

TWO aldoximes, isovaleraldoxime and cinnamylaldehyde, and two ketoximes, isobutyronoxime and isovaleronoxime, were dehydrated by passing their vapours over aluminium oxide or thorium oxide heated at 340°–360° C. (See also J. Chem. Soc., March, 1918.)—W. G.

Hydrogenation under the influence of colloidal catalysts and how to account for this process. J. Böeseken and H. W. Hofstede. Proc. K. Akad. Wetensch., Amsterdam, 1918, 20, 424–431.

MEASUREMENTS of the rate at which hydrogen is absorbed by solutions of ethyl undecylenate and of cinnamic acid and its methyl and ethyl esters in presence of colloidal palladium as catalyst, show that the hydrogenation does not follow a normal course. The irregularities are probably caused in part by impurities in the hydrogen and by coagulation of the sol. (See also J. Chem. Soc., March, 1918.)—H. M. D.

Phenylethylamine; Reduction of —. A. Weinlagen. Biochem. J., 1917, 11, 272–276.

AQUEOUS solutions of phenylethylamine hydrochloride, prepared from phenylalanine by splitting off carbon dioxide, were shaken with hydrogen in presence of finely divided platinum at the ordinary temperature (*cp.* Willstätter and Hatt, this J., 1912, 634). The calculated quantity of gas was slowly absorbed and the product was identified as hexahydrophenylethylamine. Commercial synthetic phenylethylamine, under similar conditions, absorbed no hydrogen whatever, though the platinum used was afterwards tested and found to be active. Negative results were also obtained with phenylalanine, tyrosine, and *p*-hydroxyphenylethylamine (from tyrosine). (See also J. Chem. Soc., March, 1918.)—J. H. L.

Fullers' earth; Utilisation of the adsorption power of — for chemical separations. [Adsorption of quinine and Methylene Blue.] A. Seidell. J. Amer. Chem. Soc., 1918, 40, 312–328.

THE relative adsorption capacities of some thirty-six samples of fullers' earth and similar clays have been examined by experiments in which the samples were shaken up for half an hour with solutions of quinine bisulphate and Methylene Blue of varying concentration. The free bases are readily adsorbed in both cases and the quantities adsorbed per 100 grms. of the earth afford a basis for the comparison of the adsorption capacities. In general there is a parallelism between the series of numbers obtained for the alkaloid and the dye. The numbers range from 20.0 to 0.2 in the case of quinine and from 27.8 to 0.2 for Methylene Blue. The English samples of fullers' earth had nearly the same adsorption capacity for quinine, which was considerably greater than that of the American samples examined. Several of these were found to have little adsorbent power, although a sample of unknown origin from Utah gave very good results. (See also J. Chem. Soc., March, 1918.)—H. M. D.

Gitalin (x-digiloxin); Rotatory power and molecular weight of —. J. Burmann. Bull. Soc. Chim., 1917, 21, 290–293.

GITALIN carefully prepared and purified at a temperature not exceeding 0° C. has $[\alpha]_D^{25} = -25.2^\circ$ (in chloroform) and -18.8° (in alcohol). Its molecular weight as determined by the ebullioscopic method, with chloroform as solvent, is 539. (See also J. Chem. Soc., March, 1918.)—W. G.

Lecithin. I. "Hydrolecithin" and its bearing on the constitution of cephalin. P. A. Levene and C. J. West. J. Biol. Chem., 1918, 33, 111–117.

HYDROLECITHIN is readily prepared by the reduction of lecithin with hydrogen in the presence of palladium. After recrystallisation from methyl ethyl ketone, it softens, on heating, between 80° and 90° C., turns brown about 100° C., starts to

melt about 200° and runs down the tube, giving a dark red liquid, at 235° C. As thus prepared, the hydrolecithin is not pure, but contains 20% of a substance containing amino-nitrogen, which is probably hydro-cephalin. (See also J. Chem. Soc., March, 1918.)—H. W. B.

Nitriles; New preparation of aliphatic—by catalysis. A. Mailhe. Comptes rend., 1918, 166, 121—123.

ALIPHATIC as well as aromatic nitriles may be prepared by the action of ammonia on the corresponding esters in the presence of thorium oxide or aluminium oxide at 480°—490° C. (See also J. Chem. Soc., March, 1918.)—W. G.

Nitriles; New method of formation of—by catalysis. A. Mailhe and F. de Godon. Comptes rend., 1918, 166, 215—217.

ALIPHATIC or aromatic nitriles may be prepared by passing the vapours of the corresponding aldehyde along with ammonia over thorium oxide heated at 420°—440° C. Water and some condensation products of the aldehyde and ammonia are formed at the same time. (See also J. Chem. Soc., March, 1918.)—W. G.

Sea-samphire from different parts of France; Essential oil of—. M. Delphine and G. de Belsunce. Bull. Soc. Chim., 1918, 23, 24—35.

OIL of samphire obtained from plants grown in different parts of France always contained the three characteristic constituents, 5,6-dimethoxy-3,4-methylenedioxy-1-allylbenzene, the methyl ether of thymol, and crithmene. Samples from different sources differed considerably, however, in the relative amounts of these three constituents present, and some of the oils contained in addition *p*-cymene, *d*-pinene, and a paraffin, m. pt., 63° C. (See also J. Chem. Soc., March, 1918.)—W. G.

Essential oils; Constituents of—. Gum ammoniac oil, and *synthetical experiments on the nature of its constituents.* F. W. Semmler, K. G. Jonas, and P. Roenisch. Ber., 1917, 50, 1823—1837.

THE gum-resin which is obtained from the umbelliferous plant, *Dorema ammoniacum*, and several *Ferula* species, yields about 0.3% of an oil on distillation. This is found to contain linalyl and citronellyl acetates; a unicyclic, dihydrosesquiterpene, "ferulene," $C_{15}H_{26}$, closely associated with a bicyclic sesquiterpene, $C_{15}H_{24}$, a fraction with b.pt. 124°—126° C. at 7 mm. being a mixture of these in the approximate ratio 3:1; an ethylenic, sesquiterpene-ketone, "doremone," $C_{15}H_{24}O$, b.pt. 145°—155° C. at 12 mm., amounting to about 22% of the oil, which may be reduced by means of platinum and hydrogen to tetrahydrodoremone, or by sodium and alcohol to the ethylenic alcohol, "doremol," b.pt. 145°—150° C. at 12 mm.; doremol acetate, b.pt. 155°—165° C. at 12 mm.; and cetyl alcohol, in the highest fraction. This is the first recorded instance of the occurrence of cetyl alcohol in a plant, and doremone is the first example of a sesquiterpene-ketone. The unicyclic sesquiterpene, "isoamyl- α -dehydrophellandrene," $C_{15}H_{24}$, b.pt. 130°—132° C. at 11 mm., may be obtained by the action of magnesium isoamyl iodide on carvone, and this may be hydrogenated to "isoamylmethane," $C_{15}H_{32}$, b.pt. 131°—133° C. at 14 mm. Farnesol may be hydrogenated to inactive hexahydrofarnesol, $C_{15}H_{32}O$, b.pt. 145°—155° C. at 15 mm., which is evidently closely related to the above "doremol."—J. C. W.

Essential oils; Constituents of—. *Synthetical experiments in the unicyclic sesquiterpene series.* F. W. Semmler, K. G. Jonas, and K. Oelsner. Ber., 1917, 50, 1838—1842.

THE product of the action of magnesium isoamyl

iodide on carvone (see preceding abstract) contains not only isoamyl- α -dehydrophellandrene but the normal carbinol, "isoamylcarveol," (I), b.pt. 155°—170° C. at 12 mm., which loses water when treated with potassium bisulphate, yielding the phellandrene derivative, and also "isoamylidihydrocarvone" (II), b.pt. 144°—148° C. at 10 mm., which is produced by the introduction of the isoamyl group at the double bond in the carvone ring instead of at the carbonyl group.

Iso-amylcarveol is the first synthetic unicyclic sesquiterpene alcohol, and isoamylidihydrocarvone is the first synthetic sesquiterpene-ketone.—J. C. W.

Mercury ammonia compounds. Holmes. See VII.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

- Bennis. Heat treatment of liquids and gases. 3673. Mar. 2.
 Boulton. Drying apparatus. 3637. Mar. 1.
 British Dyes, Ltd., Parker, and Turner. Filter-press. 3516. Feb. 28.
 British Thomson-Houston Co. (General Electric Co.). Manufacture of sheets by aggregation of flake materials. 3317. Feb. 25.
 Fadden. Apparatus for producing mineral distillates of definite composition. 2810. Feb. 18.
 Giesecke. 3369. *See* X.
 Hope. Apparatus for drying sand, etc. 3054. Feb. 20.
 Mangelsdorff. Dehydrating. 3144. Feb. 21.
 Meilhuizen. Drying apparatus. 3035. Feb. 20. (Holland, Mar. 31, 1917.)
 Paterson. Filtering apparatus. 3701. Mar. 2.
 Roberts. Apparatus for automatically taking samples of liquids. 2827. Feb. 18.
 Rodda. Apparatus for reclaiming heat, oils, fats, etc. 2811. Feb. 18.
 Sadezky. Producing a drying medium. 2888. Feb. 19.
 Soar. Production of permanent natural colour effects by the action of light rays on chemical matter. 3275. Feb. 25.
 Tuckfield. Continuous fractional distillation apparatus. 3356. Feb. 26.

COMPLETE SPECIFICATIONS ACCEPTED.

- 16,283 (1916). Wallace and Tiernan. Treatment of liquids with gases or purification of water. (113,288.) Feb. 27.
 2290 (1917). Rasmussen, and Ernst Ges. Separation of air or gases from liquids. (104,183.) Feb. 27.
 2579 (1917). Gee. Centrifugal separators. (113,326.) Feb. 27.
 3444 (1917). Barbet et Fils et Cie. Cooling-plates for continuous rectification apparatus. (105,549.) Mar. 6.
 6140 (1917). Perry. Apparatus for distilling. (113,373.) Feb. 27.
 6175 (1917). Wallace and Tiernan. Diffusers for use in diffusing gases in liquids. (113,374.) Feb. 27.
 12,380 (1917). Hofmann. Apparatus for drying material in bulk. (109,267.) Feb. 27.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

- Boizard. Burning inferior or anthracitic fuel in furnaces or automatic stokers. 3006. Feb. 20. (Fr., Dec. 14, 1917.)
 Clinie. Gas-producers. 2994. Feb. 20.
 Day. Extraction of hydrocarbon products from coals and shales. 3521. Feb. 27.
 Dela Devesa. Compounds for increasing the calorific value of coal, etc. 3447. Feb. 27.
 Fadden. 2810. *See* I.
 Fairweather. Washing coal gas, etc., with oil. 3506. Feb. 27.
 Firth, Blakely, Sons, and Co., and Shaw. Arrangement and operation of vertical gas-retorts. 3240. Feb. 23.

Kimber and Palmer. Retort for treating oil shale. 3173. Feb. 22.

Lynn. Producer-gas plant. 3715. Mar. 2.
 Marks (Soc. Anon. Ital. G. Ansaldo & Co.). Combustion processes. 2851. Feb. 18.
 Marks (Soc. Anon. Ital. G. Ansaldo & Co.). Simultaneously producing gas from lignite and other combustibles, and calcium phosphate for agricultural purposes. 2924. Feb. 19.
 Moorhouse and Simpson. Carbonisation and distillation of coal, etc., by electricity. 2878. Feb. 19.

Nitrogen Products and Carbide Co., and Perkin. Destructive distillation of carbonaceous materials. 2920. Feb. 19.

Rew. Water-gas producer. 3282. Feb. 28.
 Rideal and Taylor. Removal of sulphur and sulphur-containing bodies from gases. 3702. Mar. 2.

Russell. Apparatus for distilling coal, shale, peat, etc. 3232. Feb. 23.

Smith. Scrubbers, cleaners, and coolers for gas. 2832. Feb. 18.

COMPLETE SPECIFICATION ACCEPTED.

16,126 (1917). Rose. Apparatus for producing combustible fuel. (113,585.) Mar. 6.

III.—TAR AND TAR PRODUCTS.

APPLICATION.

Day. Hydrocarbon products. 3521. *See* II.

IV.—COLOURING MATTERS AND DYES.

APPLICATION.

Corbidge. Dyes. 2808. Feb. 18.

COMPLETE SPECIFICATIONS ACCEPTED.

2776 (1917). British Dyes, Ltd., Turner, and Segaller. Manufacture of N-dihydro-1,2,2',1'-anthraquinoneazine. (113,489.) Mar. 6.
 3372 (1917). Holliday and Clayton. (Production of yellow colouring-matter. (113,510.) Mar. 6.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

- Bindley and Weller. Production of dope or substitutes for celluloid, vulcanite, etc. 3502 and 3503. Feb. 27.
 Dagnall. Treatment of paper. 3598. Feb. 28.
 Dreyfus. Manufacture of uninflamable celluloid. 3336. Feb. 25. (Fr., Mar. 22, 1917.)
 Dreyfus. Manufacture of solvents for cellulose acetate, and of dopes, solutions, films, etc., there-with. 3337. Feb. 25.
 Gilchrist. Treating cotton, etc., preparatory to the production of yarns and threads. 2999. Feb. 20.
 Moore. Material for paper-making. 3202. Feb. 22.
 Murata, Ogawa, and Okubo. Production of zinc-chloride solution of cellulose. 3139. Feb. 21.
 Rafsky. Coated paper. 3235. Feb. 23.
 Zdanowich. Nitrocellulose solutions. 3172. Feb. 22.

COMPLETE SPECIFICATIONS ACCEPTED.

1224 (1916). Meiro. Treatment of flax fibre. (113,285.) Feb. 27.
 2982 (1917). Schaufelberger. Digesters for use in the manufacture of cellulose, etc. (113,494.) Mar. 6.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Ashton, and Calico Printers' Assoc. Mordanting vegetable fabrics and fibres. 3287. Feb. 25.
 Dudley. Dyeing machines. 3233 and 3234. Feb. 23. (U.S., Mar. 29 and 31, 1917.)

COMPLETE SPECIFICATIONS ACCEPTED.

8050 and 8051 (1916). Larivei. Machines for dyeing and finishing textile fibres. (113,453 and 113,454.) Mar. 6.

2610 (1917). Calico Printers' Assoc., and Fourniaux. Production of black on vegetable fibres. (113,484.) Mar. 6.

12,511 (1917). Annieq. Dyeing or similarly treating yarns in the form of hanks, skeins, or bundles. (113,575.) Mar. 6.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Coote, Thompson, and Spencer, Chapman, and Messel. Solutions of sulphuric anhydride. 3245. Feb. 23.

Curtis. Composition for manufacture of lining of acid pots, etc. 2904. Feb. 19.

General Chemical Co. Converting atmospheric nitrogen into a compound containing combined nitrogen. 3607. Feb. 28. (U.S., Nov. 3, 1917.)

Haynes and Williams. Synthetic production of ammonia. 2914. Feb. 19.

Lindblad. Production of nitrogen compounds, especially nitrates. 3057. Feb. 20.

Llewellyn, Spence, and Spence and Sons. Production of aluminous compounds. 3152. Feb. 22. Marks. 2921. *See* II.

Mineral Products Corporation. Purification of alumina. 3528. Feb. 27. (U.S., Aug. 11, 1917.)

Nitrogen Corporation. Production of substantially pure cyanogen compounds and their derivatives. 3415. Feb. 26. (U.S., June 12, 1917.)

Soar. 3275. *See* I.

Taylor. Catalysts for use in the production of hydrogen. 3703. Mar. 2.

Titan Co. Aktieselskabet. Production of titanium compounds. 3624. Mar. 1. (Norway, Mar. 23, 1917.)

COMPLETE SPECIFICATIONS ACCEPTED.

16,822 (1916). Castner-Kellner Alkali Co., and Moore. Manufacture of bleaching-powder. (113,457.) Mar. 6.

6841 (1917). Skoglund. Concentration of sulphuric acid. (113,551.) Mar. 6.

15,982 (1917). Wenman. Manufacture of phosphorus. (113,584.) Mar. 6.

17,036 (1917). Raffin et Fils. *See* X.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Barron and Barron. Artificial millstones, and manufacture thereof. 2848. Feb. 18.

Carborundum Co. (Urtel). Manufacture of abrasive articles. 3707. Mar. 2.

IX.—BUILDING MATERIALS.

APPLICATION.

Borch. Manufacture of Portland cement from raw materials with hydraulic properties. 2958. Feb. 19. (Denmark, Feb. 24, 1917.)

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Arzano and Clerici. Manufacture of iron by electrolysis. 3431. Feb. 26. (Ital., Mar. 19, 1917.)

Berglund. Extraction of lead. 2936. Feb. 19. (Sweden, Mar. 10, 1917.)

Cito. Treatment of copper sweepings and scraps. 3591. Feb. 28.

Edwards. 3536. *See* XXIII.

Fairholme and Hatfield. Refining molten metals in the process of manufacture. 3620. Mar. 1.

Giesecke. Process for solidifying conglomerates of fine ores, blue dust, purple ore, etc. 3369. Feb. 26.

Hloworth (Norsk Hydro-Elektrisk Kvaestof-aktieselskab). Connecting cast tubes of silicon-iron alloys. 3524. Feb. 27.

Humbert. Manufacture of metals in electric furnaces. 3420. Feb. 26.

Kamfield. Preparation to prevent penetration of carbon into portions of steel objects during case-hardening. 2823. Feb. 18.

Stobie. Electric steel manufacture. 2970. Feb. 20.

Sundberg. Separation of mineral values from ore by flotation. 2964. Feb. 19.

Zourieff. 3505. *See* XI.

COMPLETE SPECIFICATIONS ACCEPTED.

3285 (1917). Griffith. Electro-chemical treatment of ores. (113,508.) Mar. 6.

3398 (1917). Deutsch-Luxemburgische Bergwerks u. Hütten A.-G., and Klinkenberg. Manufacture of ingot iron and steel. (113,512.) Mar. 6.

3721 (1917). Larsen. Production of iron-sponge. (113,351.) Feb. 27.

9053 (1917). Van Gulek. Furnace especially for the treatment of zinc. (113,393.) Feb. 27.

9852 (1917). Grondal. Concentration of ores by flotation. (108,308.) Mar. 6.

10,379 (1917). Berglund. Extraction of zinc by the electro-thermal process. (109,435.) Feb. 27.

11,522 (1917). Metals Disintegrating Co. Reducing metals to a finely-divided state. (109,257.) Feb. 27.

15,682 (1917). Moll et Cie. Process for soldering aluminium. (110,758.) Feb. 27.

17,036 (1917). Raffin et Fils. Treatment of ilmenites or titanic iron ores. (111,668.) Mar. 6.

276 (1918). Richmond Gas Stove and Meter Co., and Thompson. Metal-heating, metallurgical, and like heating furnaces. (113,594.) Mar. 6.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Antonoff. Carbon conductors. 3532. Feb. 27.

Antonoff. Electric batteries. 3600. Mar. 1.

Arzano and Clerici. 3431. *See* X.

Bibby. Electric furnaces. 3726. Mar. 2.

Chloride Electrical Storage Co., and Dean. Electric accumulators. 3414. Feb. 26.

Humbert. 3420. *See* X.

Macdonald and Macdonald. Electrolytic gas process. 2877. Feb. 19.

Moorhouse and Simpson. 2878. *See* II.

Rogers. Electric resistance furnaces. 3070. Feb. 21.

Silberrad. Manufacture of electric cells. 3452. Feb. 27.

Stobie. 2970. *See* X.

Travis, and Watson and Co. Supply of electric energy to furnaces. 3460. Feb. 27.

Zourieff. Accumulators, etc. 3430. Feb. 26.

Zourieff. Production of spongy lead. 3505. Feb. 27.

COMPLETE SPECIFICATIONS ACCEPTED.

3285 (1917). Griffith. *See* X.

3807 (1917). Svenska Accumulator Aktiebolaget Jungner. Electric batteries. (108,849.) Mar. 6.

10,379 (1917). Berglund. *See* X.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Nairn. 2875. *See* XIII.

Rodda. 2811. *See* I.

COMPLETE SPECIFICATION ACCEPTED.

4711 (1917). Downs and Bellwood. Apparatus for extracting oil from seeds and like oleaginous materials. (113,530.) Mar. 6.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Bindley and Weller. Synthetic shellac, resin, etc., and methods of producing same. 3501. Feb. 27.

Corticine Floor Covering Co., and Thompson. Cement, and method of making same for use in the manufacture of linoleum, etc. 3348. Feb. 26.

Darrin and Sperr. Manufacture of resins. 3664. Mar. 1.

Murray. Manufacture of water paint, etc. 3394. Feb. 26.

Nairn. Treatment of fatty acids for use in manufacture of linoleum. 2875. Feb. 19.

Titan Co. Aktieselskabet. Pigments. 3549. Feb. 28. (Norway, Feb. 28, 1917.)

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATION.

Bindley and Weller. 3501. *See V.*

COMPLETE SPECIFICATIONS ACCEPTED.

12,085 (1917). Peachey. Agents for accelerating vulcanisation of rubber, and method of producing them. (113,570.) Mar. 6.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATION.

Heyl. Drying japanned or patent leather. 3053 and 3143. Feb. 20 and 21. (Ger., May 22, and Apr. 27, 1916.)

COMPLETE SPECIFICATIONS ACCEPTED.

2197 (1917). Röhm. Tanning processes. (104,338.) Feb. 27.

13,036 (1917). D'Angelo. Apparatus for tanning hides. (113,408.) Feb. 27.

14,862 (1917). Röhm. Tanning or tawing by means of aluminium salts. (110,750.) Mar. 6.

XVI.—SOILS; FERTILISERS.

APPLICATION.

Marks (Soc. Anon. Ital. G. Ansaldo & Co.). 2924. *See II.*

COMPLETE SPECIFICATIONS ACCEPTED.

2924 (1917). Borghesani and Stampa. Fertilisers. (113,493.) Mar. 6.

12,186 (1917). Richards. Treatment of straw and other vegetable substances for manurial purposes. (113,571.) Mar. 6.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATION.

Herriot (Deerr.). Apparatus for macerating bagasse. 3471. Feb. 27.

XVIII.—FERMENTATION INDUSTRIES.

COMPLETE SPECIFICATIONS ACCEPTED.

2683 (1917). Stevenson. Production of a blended yeast. (113,486.) Mar. 6.

8677 (1917). Hadley. Non-intoxicating beer, and process of brewing the same. (113,560.) Mar. 6.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Bugler. Manufacture of egg substitute. 3357. Feb. 26.

Dantzig, and Naamil. Vennootsch. Chemisch and Pharmaceutisch Laboratorium. Preservation of vegetables and fruits. 3132. Feb. 21.

Dowding. Treatment of potatoes for obtaining food products. 3523. Feb. 27.

Growcott. Treatment of grain, etc. 3510. Feb. 27.

Lyle. Combined food and beverage. 3625. Mar. 1.

Mackay. Disinfecting and refrigerating. 3364. Feb. 26.

Mangelsdorff. Preparing potatoes for dehydration. 3145. Feb. 21.

Norton. Manufacture of margarine. 3609. Feb. 28.

Stokes. Incinerating furnaces. 3385. Feb. 26.

COMPLETE SPECIFICATIONS ACCEPTED.

16,283 (1916). Wallace and Tiernan. *See I.*
2761 (1917). Jones, and Jones and Attwood. Purification of sewage and other liquids. (113,333.) Feb. 27.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Comp. des Prod. Chimiques d'Alais et de la Camargue. Preparation of acetic aldehyde from acetylene. 3589. Feb. 28. (Fr., Jan. 12, 1917.)

Comp. des Prod. Chimiques d'Alais et de la Camargue. Preparation of acetic acid by oxidation of ethylaldehyde. 3590. Feb. 28. (Fr., Mar. 6, 1917.)

Garroid and Nielsen. Catalytic manufacture of formaldehyde, etc., from hydrocarbons. 3632. Mar. 1.

COMPLETE SPECIFICATIONS ACCEPTED.

2151 (1917). Inray (Soc. Chem. Industry in Basle). Manufacture of a new physiologically active substance and compounds containing nitrogen from ovaries, corpus luteum, or placenta. (113,311.) Feb. 27.

2896 (1917). Parke, Davis, and Co. Anæsthetic bodies. (106,087.) Mar. 6.

2928 (1917). Parke, Davis, and Co. Anæsthetic bodies. (105,746.) Mar. 6.

3244 (1917). Simpson. Treatment of liquids for curative and therapeutical purposes. (113,505.) Mar. 6.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

Bateman. Kinematograph films. 3491. Feb. 27.

Camiller and Lyell. Films, screens, or plates for natural-colour photography. 3115. Feb. 21.

Camiller and Lyell. Films or screens for kinematography. 3116. Feb. 21.

Hess-Ives Corporation. Coloured photographic image, and method of producing same. 2910. Feb. 19. (U.S., Feb. 20, 1917.)

Hess-Ives Corporation. Colour photography. 2911. Feb. 19. (U.S., Feb. 20, 1917.)

XXII.—EXPLOSIVES; MATCHES.

APPLICATIONS.

Holloway and Summers. Matches ignited by friction. 2865. Feb. 18.

Tonge. Matches. 2976. Feb. 20.

Zdanowich. 3172. *See V.*

XXIII.—ANALYSIS.

APPLICATIONS.

Edwards. Testing hardness of metals, and instrument therefor. 3536. Feb. 28.

Michell. Determining viscosity of fluids. 3124. Feb. 21. (Australia, July 12, 1917.)

Roberts. 2827. *See I.*

I.—GENERAL; PLANT; MACHINERY.

PATENTS.

Cooling and otherwise treating gases with liquids; Apparatus for —. A. W. Mathys, London. Eng. Pat. 111,113, Nov. 8, 1917. (Appl. No. 16,389 of 1917.) Under Int. Conv., Nov. 8, 1916.

IN an apparatus for humidifying or cooling air by contact with water, a tank containing water is divided by vertical partitions into compartments which communicate at the bottom. Each compartment contains a number of vertical plates spaced apart to form narrow passages and mounted in skeleton frames or cages, each pair of adjacent frames being suspended by a cable or chain passing over a pulley. The pulleys are oscillated so that the plates are alternately raised from and lowered into the water, the velocity of the frames being at a minimum at the two ends of their travel. Air enters at the side of the casing and passes between the plates in each frame in succession, openings being provided in the partitions above the water level at different heights alternately, so that the air is forced to take a zigzag path.—W. F. F.

Furnaces or mufles; Gas heated —. J. M. Wallwin, Warwick. Eng. Pat. 112,747, Sept. 4, 1917. (Appl. No. 12,616 of 1917.)

THE body of the furnace is formed of a tubular member, having openings in the sides for the admission of the material to be heated and the fuel, i.e., gas and air. The ends are recessed to receive top and bottom plates, which are clamped in position between metal flanges. Outlet openings for the products of combustion are provided at the top and inlet openings at the bottom of the second and subsequent furnaces when two or more furnaces are arranged in tiers. The lowermost metal flange is provided with a bracket to which the furnace door is hinged. The top member is provided with a plain dished flange with a hole in the centre. The furnaces are held together by bolts passing through from top to bottom.—J. H. P.

Furnaces and the like. I. Hall, Birmingham. Eng. Pat. 112,827. (Appl. Nos. 1557, Jan. 31, and 2184, Feb. 20, 1917.)

THE furnace is provided with four forced-draught burners for burning coal gas, producer gas, petrol gas, high pressure gas, or liquid fuel, discharging tangentially into the heating or melting chamber. Two of the burners are set 180° apart, but not at the same level, at the lower end of the chamber, and the other two are similarly placed at a higher level, the lines joining each pair being at right angles in plan. The burners are preferably arranged on an imaginary helical line. The escape of the combustion gases is delayed by providing one or more helical grooves or channels in the refractory lining of the heating chamber, or by means of projecting helical ribs. Two reservoirs may be provided for the gas and air respectively, with separate outlets for each of the burners.

—W. F. F.

Kiln. C. W. Bowsman, Joliet, Ill. U.S. Pat. 1,251,333, Dec. 25, 1917. Date of appl., July 12, 1917.

THE baking chamber is heated by means of peripheral combustion chambers, and the waste gases are discharged through slots in the floor of the chamber into radial flues leading to a discharge funnel. By suitable adjustment of the area and capacity of the several slots and flues a substantially equal volume of the gases is drawn through each flue.—J. H. P.

Kiln. J. L. Harper, Niagara Falls, N.Y., U.S.A. U.S. Pat. 1,253,487, Jan. 15, 1918. Date of appl., Apr. 29, 1910. Renewed Dec. 1, 1917.

SEE Fr. Pat. 404,208 of 1909; this J., 1910, 98. Flues are provided through which gas may be introduced into the electrically heated middle portion of the kiln.

Separating solids from liquids; Means for —. G. A. Spratt, Chingford, Essex. Eng. Pat. 112,791, Jan. 3, 1917. (Appl. No. 151 of 1917.)

IN an apparatus for separating a liquid from solid matter suspended in it, e.g., for purifying cutting and cooling oils from metallic particles, a centrifugal pan of oval shape in vertical cross-section is provided with a wide central opening at the top into which the liquid is supplied and over the rim of which the purified liquid overflows. A small central opening is provided in the bottom of the pan and a flanged sleeve, projecting upwards into the vessel and closed at the top, is secured over the opening. A bearing plate is secured to the underside of the pan which rests on a washer supported on a horizontal flange carried by the vertical driving shaft. The shaft is extended upwards into and concentric with the closed sleeve, leaving an annular space between the two. The pan is rotated by frictional contact with the washer, and rotates about its centre of gravity so that vibration is avoided. The pan is surrounded by a casing in which the purified oil collects. In a modification, the pan is rigidly connected to the driving shaft and the liquid is supplied through a central opening in the shaft. A cover may be provided, the purified liquid then escaping through perforations in the wall of the pan close to the edge of the cover.—W. F. F.

Mixing and cooling machine. F. A. Connolly, Pompton Lakes, N.J. U.S. Pat. 1,250,435, Dec. 18, 1917. Date of appl., Jan. 22, 1917.

A DRUM provided with internal vanes arranged obliquely, and a central hollow shaft are mounted in a frame so that they can be rotated in opposite directions. Parallel radial hollow blades are mounted on the shaft and are connected together at their outer ends. A cooling medium passes through the shaft and blades, and means are provided for supplying material to and removing it from the drum.—J. H. P.

Fractional distillation and condensation; Process and apparatus for —. J. W. Aylsworth, East Orange, N.J., Assignor to Condensate Co. of America, Bloomfield, N.J. U.S. Pat. 1,250,760, Dec. 18, 1917. Date of appl., Nov. 9, 1915.

THE apparatus comprises a still connected to one end of a horizontal condensing coil contained in a closed receptacle, the coil having a condensing surface at least ten times as great as the evaporating surface of the still. The other end of the coil is connected to a second water-cooled coil, and means are provided for observing the temperature in the connecting pipe as well as in the receptacle. The liquids condensing in the bottom loops of the horizontal coil are led back to the still. A heating fluid is rapidly circulated from a heater through the receptacle and around the horizontal coil by means of a pump, the supply of heat being regulated by an adjustable thermostat governed by the temperature of the fluid in the receptacle, so that this is maintained at any desired one of several temperatures, in accordance with the temperatures indicated in the connecting tube between the coils and in the receptacle.—B. N.

Liquids having different boiling points; Art of separating — G. R. Sanford, T. H. Miller, and B. Torrey, jun., Syracuse, N.Y., Assignors to Semet-Solvay Co., Solvay, N.Y. U.S. Pat. 1,252,725, Jan. 8, 1918. Date of appl., Mar. 29, 1916.

THE mixture is distilled and the vapour condensed in a dephlegmating column, so that the upper part of the column contains only liquid having the lowest boiling point, the other condensates passing downward to the lower part of the column. The distillation is stopped when all the liquid of lowest boiling point has been distilled from the charge, the residue is removed, and the operation is repeated with a fresh charge.—W. F. F.

Drying machine. C. Crouch and G. J. Hewlett, Cleveland, Ohio. U.S. Pat. 1,250,980, Dec. 25, 1917. Date of appl., Sept. 9, 1916.

A FLUID-JACKETED revolving drum is provided with stationary and gland-bearing heads. Fluid conduits communicate with the latter and with the drum, and means are provided in some of the conduits for trapping liquid out of the lower portion of the drum at regular intervals. The material to be dried passes through the drum in an opposite direction to the fluid in the jacket, and means are provided for increasing or decreasing the resistance offered to the passage of the material and fluid through the drum and jacket respectively.—J. H. P.

Drying materials; Art of — A. F. Wright, East Orange, N.J. U.S. Pat. 1,251,317, Dec. 25, 1917. Date of appl., Mar. 18, 1916.

THE material to be dried is distributed over superposed shelves having heaters placed adjacent thereto. A heated drying atmosphere is circulated through the spaces between the shelves and the heaters, and, by means of deflectors, eddy currents are set up, whereby intimate contact of the drying atmosphere with the material and with the heaters is obtained.—J. H. P.

Refrigeration. F. G. Keyes, Hoboken, N.J., Assignor to National Automatic Refrigerator Co. U.S. Pat. 1,251,538, Jan. 1, 1918. Date of appl., May 27, 1916.

A LIQUID refrigerating composition consists of water, an active absorbent such as ammonium nitrate, and a volatile refrigerating component, such as ammonia, the proportions being such that on applying a vaporising temperature of 100° C. the ratio of water to ammonia in the vapour evolved is not greater than in the critical boiling mixture thereof at 0° C.—J. H. P.

Precipitation of particles from fluid streams; Art of electrical — C. W. Girvin, Assignor to U. G. Scott, Philadelphia, and H. G. Seitz, New York. U.S. Pat. 1,252,104, Jan. 1, 1918. Date of appl., Mar. 22, 1917.

OPPOSING electrode systems are so arranged that an electric field is produced having permanently located active and inactive portions, and means are provided for rotating the collecting-electrode system on its axis to move a deposit-collecting face between an active and an inactive portion and for removing the deposit whilst it is in the inactive zone.—J. H. P.

Air; Apparatus for treating — with liquids. J. H. Lorimer, Philadelphia, Pa. U.S. Pat. 1,253,401, Jan. 15, 1918. Date of appl., July 9, 1914.

A HORIZONTAL conduit is provided at its lower part with a tank for containing liquid, and at its upper part with a deflecting plate extending obliquely downwards and backwards. A number of transverse shafts are provided above the tank geared to rotate together and carrying sets of parallel discs on each shaft partly dipping into the liquid.

The plane of the discs is thus parallel to the air current, which is caused to flow through the conduit by a fan, and the discs on one shaft are out of alignment with and overlapping those on the adjacent shaft. The upper edges of the discs fit closely to the deflecting plate.—W. F. F.

Washing and drying machine; Centrifugal — R. C. McCaleb, Chicago, Ill. U.S. Pat. 1,253,403, Jan. 15, 1918. Date of appl., Apr. 3, 1917.

IN a centrifugal washing and drying machine a cylindrical container is provided with an internal basket mounted on a vertical rotating shaft. A member movable vertically carries a bucket which may be moved upwards and downwards through a central opening in the bottom of the basket. The basket and shaft are adapted to be tilted into two different positions, in which the shaft engages with worm and spur driving gear respectively, so that the basket may be rotated at two different speeds.—W. F. F.

Centrifugal machine. L. Salcines, Guantánamo, Cuba. U.S. Pat. 1,253,428, Jan. 15, 1918. Date of appl., Jan. 3, 1916.

A CASING, C, contains a rotating basket, B, to which the material to be treated is fed from the trough, 3, through the cylindrical chamber, P.

A valve, 11, controlling the discharge from the trough, 3, to the chamber, P, is reciprocated by the electromagnet, 13, through the pivoted lever, L. A series of cylinders, 8, is arranged radially around the chamber, P, and each is provided with a piston normally pressed into the cylinder, P, by a spring. The pistons are pressed outward by the pressure of the material in the chamber and thus complete the electric circuit of the electromagnet, 13, which then opens the valve, 11. The feed of the material is thus controlled by the pressure of the material in the feeding chamber, P.—W. F. F.

Filters; Process of cleaning — in connection with the purification of sugar, oils, and chemicals. P. L. Wooster, Yonkers, N.Y., U.S.A. Eng. Pat. 109,795, Aug. 10, 1917. (Appl. No. 11,541 of 1917.) Under Int. Conv., Aug. 17, 1916.

SEE U.S. Pat. 1,240,290 of 1917; this J., 1917, 1121.

Desiccation [of liquids]; Process of — and apparatus therefor. H. Wade, London. From G. A. Buhl, Chicago, U.S.A. Eng. Pat. 112,965, Dec. 29, 1916. (Appl. No. 18,632 of 1916.)

SEE U.S. Pat. 1,215,889 of 1917; this J., 1917, 376.

Distillation of liquids. O. Söderlund and T. Boberg, Assignors to Techno Chemical Laboratories, Ltd., London. U.S. Pat. 1,252,962, Jan. 8, 1918. Date of appl., Dec. 10, 1914.

SEE Eng. Pat. 28,537 of 1913; this J., 1915, 68.

Machine for mixing concrete and the like. Eng. Pat. 107,575. See IX.

Process of drying grain and other coarse granular materials. U.S. Pat. 1,250,496. See XIX A.

II A.—FUEL; GAS; MINERAL OILS AND WAXES.

Fuels; Determination of total carbon in — and its importance in the study of fuel economy. E. Damour and M. de la Morinière. Rev. Mét., 1917, 14, 789—800.

IN considering the heat economy of a fuel the total carbon content has an importance not generally recognised. Few laboratories are capable of estimating this content rapidly, and in general a commercial analysis including ash, fixed carbon, volatile matter, and sometimes calorific power is considered sufficient. In making a balance-sheet of heat production and consumption in an industrial furnace, it is impossible to calculate the amount of heat lost outside the furnace without using a term of comparison common to the fuel and to the gaseous waste products of combustion. From the content of total carbon in the fuel it is possible to calculate the volume or weight of gaseous products of combustion. The apparatus used by the authors for the determination of total carbon is a combination of the Mahler-Goutal bomb (fitted with an additional outlet) with the usual absorption tubes generally associated with the combustion furnace in organic analysis. 0.5 gm. of the fuel, contained in a silica capsule, is introduced into the apparatus. After the explosion, and on opening the connection to the tared absorption vessels, the gases circulate through sulphuric acid, soda-lime, potash, and pumice stone moistened with sulphuric acid. A large Maquenne tube charged with 50 c.c. of de Nolly's solution (alkaline solution containing about 4 grms. of soda per litre) indicates any loss of carbon dioxide due to failure to regulate the speed of gas flow. In this way it is possible to determine in 1½ hours the total carbon of the fuel. Tests have shown that the losses due to the residue from combustion, and formation of carbon monoxide or of hydrocarbons are negligible. A correction is made for the carbon dioxide remaining in the bomb. To ensure complete combustion and to reduce the error possible from the amount of space in the bomb, the authors recommend a smaller bomb of 250 c.c. capacity and adapted for a pressure of 25 atmospheres. From the results of tests conducted as above, the authors give elaborate calculations leading to a thermal balance-sheet of a battery of boilers and of an open-hearth furnace respectively.—J. E. C.

Water-gas; Production of — in continuous vertical retorts. H. M. Balsam. Gas J., 1918, 141, 247—248.

THE author discusses the advantages of making water-gas, *in situ*, in a continuously worked vertical retort, the speed of the descent of the charge being adjusted to leave an ample depth of incandescent coke, and steam at 40 lb. per sq. in. being introduced somewhat on the lines indicated by West (see this J., 1917, 1265; 1918, 26 A). The following results are given relating to normal working and to "combination" working respectively: Gas per ton, 14,120 and 27,390 cub. ft.;

calorific value, 540 and 436 B.Th.U.; candle power, 14.5 and 5.0; gas produced per retort in 24 hours, 738 and 950 cub. metres.—J. E. C.

Illuminating gas; Washing of — with anthracene oil. M. Raffo and G. Scagliarini. Annali Chim. Appl., 1917, 8, 114—121.

THE increase in the sp. gr. of anthracene oil which has been used for several months for extracting benzene, etc., from gas is not due to naphthalene. Fractional distillation of a sample of anthracene oil which had thus been used gave the following results:—Between 200° and 230° C. a liquid distilled which yielded 2.09% of naphthalene and 7.75% of liquid residue, whilst between 230° and 270° C. there distilled 6.16% of an oil yielding 1.08% of naphthalene. These results compared with those given by a sample of saturated anthracene oil show that the amount of naphthalene left in solution in the tar is somewhat greater than that dissolved by the oil. The increase in the sp. gr. of the anthracene oil is due to the presence of various products boiling between 270° and 330° C., principally fluorene, phenanthrene, and acenaphthene. The increase in the sp. gr. of the oil has no material influence on the extraction of light oils from the gas, and after 4 months' use an oil will extract almost the same amount of benzene as when first used. Anthracene oil can be used for extracting light oils until mechanical conditions prevent its movement within the washing chamber.—C. A. M.

PATENTS.

Alcohol; Method of rendering — more readily ignitable when used as fuel in internal combustion engines. P. H. King and J. A. Stoneham, London. Eng. Pat. 112,741, Aug. 10, 1917. (Appl. No. 11,478 of 1917.)

ALCOHOL is vaporised and mixed with an equal volume of acetylene. The mixture is then condensed in the ordinary manner, the liquid holding the acetylene in solution.—J. E. C.

[Gas retort] furnace; Regenerative —. S. B. Russell, Assignor to Parker-Russell Mining and Manufacturing Co., St. Louis, Mo. U.S. Pat. 1,251,426, Dec. 25, 1917. Date of appl., Jan. 15, 1917.

IN a gas retort setting heated by producer gas, the primary air circulates round a waste heat flue in the recuperator. Steam is introduced through steam jets or injecting nozzles in close proximity to the ports in the division wall between the gas producer and the recuperator so as to cause a mixture of heated primary air and steam to be supplied to the producer.—J. E. C.

Gas producers. F. Thuman, Westminster. Eng. Pat. 112,909, Sept. 25, 1917. (Appl. No. 13,770 of 1917.)

IN a gas producer, a steam- and blast-distributing grate projects through an eccentrically disposed aperture in the ash-pan into the fuel bed and is caused by the rotation of the ash-pan to gyrate, means being provided for coupling the grate to the ash-pan when desired, so that it will then also rotate about its axis.—J. E. C.

Gas producer. J. R. George, Assignor to Morgan Construction Co., Worcester, Mass. U.S. Pat. 1,251,011, Dec. 25, 1917. Date of appl., Feb. 6, 1915.

A GAS producer is fitted with a rotating ash support and a scraper which normally rotates with this support. By means of gear responsive to changes in the level of the fuel bed, a stop can be interposed in the path of the scraper to prevent its rotation.—J. E. C.

Gas producer. E. A. W. Jefferies, Assignor to Morgan Construction Co., Worcester, Mass. U.S. Pats. (A) 1,251,038 and (B) 1,251,039, Dec. 25, 1917. Dates of appl., Aug. 2, 1913, and Dec. 16, 1914.

(A) A GAS producer comprises a fuel section, to which fuel is fed during the operation of the producer, a fuel levelling device resting on the surface of the fuel and capable of adjustment to the level of the bed, with means for causing relative rotation between the fuel section and the levelling device. (B) A bed of fuel is supported in a gas producer, and the surface levelled by a swinging arm pivoted at one end on a horizontal axis and resting by gravity on the surface of the fuel bed. Means are provided for ensuring relative rotation between the levelling arm and the fuel bed.—J. E. C.

Gas generators; Steam and air mixer for —. F. Logan, Phoenixville, Pa. U.S. Pat. 1,251,252, Dec. 25, 1917. Date of appl., June 16, 1916.

A STEAM and air mixer consists of a casting having an upper hollow portion, to which air and steam are supplied through separate pipes, and an integral annular retarding chamber forming the lower portion of the casting. There are openings in the opposite side walls of this chamber, one opening being closed by a plug and the other being fitted with a discharge pipe which extends through the wall of the generator to the space beneath the grate.—J. E. C.

Fuel; Apparatus for producing combustible —. J. R. Rose, Edgeworth, Pa. U.S. Pat. 1,252,032, Jan. 1, 1918. Date of appl., Nov. 29, 1915.

A PAIR of vertical and parallel flues, each filled with refractory material in chequered formation, is arranged in a generator, the upper ends being connected by a transverse passage. A combustible fluid, together with a regulated supply of air, is admitted to the lower end of one of the flues, and a liquid hydrocarbon, preheated in a passage between the two flues, is admitted about half-way up the flue.—J. E. C.

Fuel; Process of manufacturing gaseous —. J. R. Rose, Edgeworth, Pa. U.S. Pat. 1,252,033, Jan. 1, 1918. Date of appl., May 19, 1916.

SUPERHEATED steam and a hydrocarbon fluid are passed through a duct heated to at least 2200° F. (1200° C.) to induce dissociation. A heated mixture of liquid hydrocarbon and superheated or dried steam is then added, the final mixture passing through another duct also heated to at least 2200° F. (1200° C.). Carbon dioxide is then removed from the gaseous product.—J. E. C.

Distilling hydrocarbons; Art of —. J. W. Coast, jun., Tulsa, Okla. Assignor to The Process Co. U.S. Pat. 1,252,401, Jan. 8, 1918. Date of appl., Nov. 11, 1916.

PETROLEUM distillates having a boiling point of over 300° F. are mixed with steam and forced at a velocity greater than 2600 ft. per minute through a coil of small pipe at a pressure of 50 to 150 lb. per sq. in., and between 850° and 1500° F., into a cracking chamber into which is also injected a finely divided and relatively cool petroleum distillate. This latter is thereby also cracked; the fractions of high boiling point are condensed, and carbon or coke removed from the vapours. The remaining vapours are led off and condensed.—L. A. C.

Hydrocarbonaceous or bituminous product and process of making the same. T. M. Hart, Assignor to P. M. Stewart, New York. U.S. Pat. 1,252,433, Jan. 8, 1918. Date of appl., Sept. 30, 1915.

ASPHALT is mixed with alum, whereby the water

of emulsification is converted into water of crystallisation. The mixture is heated below the temperature at which water is evolved.—L. A. C.

Distilling oil and other liquids; Process of and apparatus for —. W. Thomas, Nainaimo, British Columbia. U.S. Pat. 1,253,747, Jan. 15, 1918. Date of appl., Feb. 2, 1917.

GAS, heated in a regenerator situated below the heating chamber of the still, is passed under pressure into an "injector-circulating device" situated within the still, drawing with it the top layer of liquid and foam into the body of the liquid, and thus assisting vaporisation and preventing boiling over. Waste hot products from the regenerator are led into the heating chamber of the still.—L. A. C.

Cracking hydrocarbons; Art of and apparatus for —. J. W. Coast, jun., Assignor to The Process Co., Tulsa, Okla. U.S. Pats. 1,252,999 and 1,253,000, Jan. 8, 1918. Date of appl., May 22, 1917.

A HOLLOW movable shield, cooled by water, is placed between the still and the heating medium in order to protect overheated portions of the still.—L. A. C.

Coke-oven. T. von Baner, Tantenburg, Germany, Assignor to B. Zwillinger, New York. U.S. Pat. 1,253,445, Jan. 15, 1918. Date of appl., July 11, 1913.

SEE Ger. Pat. 262,116 of 1912; this J., 1913, 901.

Process of making sodium ferrocyanide. U.S. Pats. 1,252,711 and 1,252,742. See VII.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Destructive distillation of Philippine wood. A. H. Wells, Philippine J. Sci., 1917, 12, A, 111—125.

THE experimental plant consisted of a cylindrical iron retort capable of holding 10 to 15 kilos. of wood and heated electrically in such a manner that the inside temperature could be controlled over a range of 500° C. The vapours passed into a tar trap, a piece of iron pipe 10 cm. in diameter, capped at each end and fitted with a pet-cock at the bottom, and then into a condenser and scrubber consisting of a coil of lead piping 2.5 cm. in diameter, fitted into a barrel and leading to a small tower containing pieces of glass tubing. Both fast and slow distillations were made on each kind of wood; in the former the current was not controlled, except at the beginning of the exothermic reaction (265°—275° C.), during which period it was shut off in order to prevent loss by overtaxing the condensing system; in the latter, the current was so applied that the apparent moisture was driven off first, a pause in the distillation marking the end of this stage (121°—180° C.); the current was then gradually increased and subsequently was shut off for the period of the exothermic reaction, after the completion of which it was raised slowly to about 330° C., and then rapidly to 550° C. The highest yields of wood alcohol and acetic acid were obtained from hard mangrove woods, the lowest from soft woods with the highest resinous content. Controlled distillations in all cases gave higher yields of methyl alcohol and generally of acetic acid. Acetone, aldehyde, and higher ketonic compounds were found in most of the distillates. The tars obtained were fractionally distilled, yielding below 100° C. colourless inflammable oils with a strong characteristic odour and having sp. gr. 0.958—0.998. The fraction from 150° to 250° C. varied from pale yellow to brown, and quickly darkened in colour; sp. gr. 1.010—1.028. The green and blue oils began to pass over at 230° C.; these were accompanied by a small amount of

water, indicating decomposition, and contained a high percentage of substances which reacted with alkali. The fractions above 250° C. were semi-solid and usually red. The pitch was vitreous, with conchoidal fracture and of rather high melting point. All of the specimens of charcoal would be suitable for domestic purposes, and some of them for iron smelting. The author discusses costs and working expenses for wood distillation on the large scale in the Philippine Islands. Percentage yields of various products from different woods are given in the following table:—

Wood.			Pyrolog- neous distillate.	Tar.	Non-con- densable gases,*	Charcoal.	Methyl alcohol.	Acid (as 100% acetic acid).

PATENTS.

Distillation of coal, oil shales, and other similar carbonaceous materials. S. B. Billbrough, Johannesburg, Transvaal. Eng. Pat. 112,793, Jan. 11, 1917. (Appl. No. 576 of 1917.)

THE material is distilled at a high temperature (800° to 1200° C.) and the vapours are withdrawn through a passage remote from the walls of the retort. This passage may consist of a central perforated tube, decreasing in cross-sectional area from the top to the bottom of the retort, and may be rotated if desired. The perforated tube may be covered with wire gauze or netting if desired. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 3334 of 1875, 2312 of 1883, 11,581 of 1890, 15,486 of 1894, 30,673 of 1897, 19,143 of 1900, 16,925 and 29,313 of 1909, and 4598 of 1915; this J., 1891, 689; 1895, 645; 1899, 255; 1901, 1100; 1910, 1049, 1366; 1916, 919.)—J. E. C.

Oil shales; Distillation of —. G. E. Heyl, London. Eng. Pat. 112,997, Feb. 6, 1917. (Appl. No. 1865 of 1917.)

BEFORE distillation, shale is soaked for a long period, e.g., 24 hrs., in a relatively small volume of a liquid hydrocarbon, such as mineral oil or coal-tar oil. The distillation is preferably effected in two or more stages, a further quantity of the hydrocarbon being added between each. For example, a volume of coal-tar oil distilling up to 220° C., equal to 10% of the mass of the shale, is used to soak the shale and the mixture distilled to 220° C. After cooling, the still residue has added to it a further 10% of the shale and the distillation is continued to 400° C. The yield of oil, less the added 20% of coal-tar oil, will be greater than would be obtained without the addition of the oil.—L. A. C.

Heat-developing apparatus. W. A. Bone and J. W. Wilson, Leeds, and C. D. McCourt, Assignors to Radiant Heating, Ltd., London. U.S. Pat. 1,253,342, Jan. 15, 1918. Date of appl., Feb. 20, 1912. Renewed June 11, 1917.

SEE Eng. Pat. 2401 of 1911; this J., 1912, 110.

III.—TAR AND TAR PRODUCTS.

PATENT.

Distilling hydrocarbons or liquids likely to form emulsions; Apparatus for treating or —. F. M. A. A. Melchoir, Assignor to Soc. Anon. des Combustibles Industriels, Paris. U.S. Pat. 1,253,411, Jan. 15, 1918. Date of appl., Sept. 13, 1912.

SEE Eng. Pat. 17,954 of 1912; this J., 1913, 904.

IV.—COLOURING MATTERS AND DYES.

PATENTS.

Dye stuffs and dyes; Manufacture of —. N. Malcolmson, London. Eng. Pat. 112,813, Jan. 24, 1917. (Appl. No. 1228 of 1917.)

CERTAIN carbonaceous materials, such as plants of the algae family, ferns, peat, or used tea-leaves, are heated with a concentrated mineral acid, and the saturated solution thus produced is evaporated to dryness or to a paste, any residual acid being neutralised by sodium carbonate, caustic soda, or other suitable neutralising agent. To increase the solubility of the dye, sodium chloride, sugar, or other soluble material may be added either to the mixture in the retort or to the paste or powder, also, other dyestuffs, mordants, or topping bath materials may be added in the same way. The acid vapours evolved are condensed and the resulting liquid used again.—L. A. C.

Colouring bodies; Preparation of — for use in food, pharmaceutical and other preparations. A. Boake, Roberts and Co., Ltd., and T. Rendle, London. Eng. Pat. 112,886, May 17, 1917. (Appl. No. 7105 of 1917.)

THE dye, or other colouring matter, is dissolved in a heated salt such as sodium thiosulphate, sodium carbonate, sodium sulphate, sodium phosphate, magnesium sulphate, alum, and others which on heating melt in their own water of crystallisation. The mixture is cooled, allowed to set, and formed into blocks, slabs, or masses, or reduced to powder. A solution containing up to 15 to 20% of the colouring matter can be obtained. —L. A. C.

[Anthracene] vat dyes; Bluish-green — and process of making them. M. Kardos, Charlottenburg, and P. Nawiaskey, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen, Germany. U.S. Pat. 1,253,252, Jan. 15, 1918. Date of appl., Apr. 15, 1914.

SEE Addition of Feb. 13, 1914 to Fr. Pat. 458,949 of 1913; this J., 1915, 22.

Method of preparing nitroso compounds from ligninsulphonic acid. Eng. Pat. 103,653. Sec V.

Nitration of cotton cellulose and influence of prolonged bleaching on its transformation into dinitrocellulose. Namias. Sec XXII.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

PATENTS.

Fulling and materials for use therein. K. Mohs, Allach, Germany. Eng. Pat. 110,343, June 25, 1917. (Appl. No. 9118 of 1917.) Under Int. Conv., Oct. 12, 1916.

A COMBINATION of organic colloids with inorganic protecting colloids is prepared in a solid and soluble form and a small proportion of the colloid powder is added to the fulling liquor, whereby quicker felting and less shrinkage are obtained. For the preparation of the colloid a mash is made with a material, such as Indian seaweed, "Indian bread or Tuckakoe," Japanese seaweed, or Iceland moss, and a solution containing about 2% of potassium carbonate, which is raised to 55° C. The filtered infusion is evaporated under vacuum with a certain proportion of colloidal silicic acid, and when concentrated to a suitable consistence, the mixture is discharged and mixed with a further portion of the silicic acid so that the mixture is solidified and obtained as a dry powder. For instance, 1000 kilos. of Iceland moss yields about 300 kilos. of air-dry organic colloid substance, which is combined with about 200 kilos. of colloidal silicic acid yielding 500 kilos. of air-dry solid colloid powder.—J. F. B.

Cellulose; Process of dissolving—. E. C. R. Marks, London. From International Cellulose Co., Reno, Nevada, U.S.A. Eng. Pat. 104,173, Jan. 31, 1917. (Appl. No. 1564 of 1917.)

SEE U.S. Pat. 1,218,954 of 1917; this J., 1917, 450. Sulphuric acid may be used instead of phosphoric acid, and the hydrochloric acid should contain not less than 25% by weight of hydrogen chloride. When it is desired to obtain a solution of sugars (dextrose and pentoses) by hydrolysis of the cellulose, the amount of water present in the initial mixture of cellulose and acids should not exceed one-fifth of the weight of cellulose.

Cellulose solutions; Spinning copper oxide ammonia—. E. Elsaesser, Langerfeld, Germany. Eng. Pat. 113,010, Feb. 19, 1917. (Appl. No. 2438 of 1917.)

IN apparatus for spinning threads from cuprammonium solutions of cellulose, in which flowing liquids are used for feeding the threads, air bubbles in the precipitating liquid disturb the formation of the thread. To prevent these bubbles the precipitating liquid is freed from dissolved gases, for instance, by subjecting it, preferably while hot, to the action of a vacuum.—J. F. B.

Viscose: Process of making—. N. E. Katz, Meridian, Miss. U.S. Pat. 1,251,237, Dec. 25, 1917. Date of appl., Aug. 28, 1917.

ALKALI-CELLULOSE containing an excess of alkali is caused to react directly with carbon bisulphide associated with an organic plasticising agent and a solvent for the same.—J. F. B.

Paper-making and like machines; Fell-driers for—. W. A. Aitken, Gravesend. Eng. Pat. 112,678, Jan. 25, 1917. (Appl. No. 1240 of 1917.)

THE lower drying felt of a paper machine is carried round a large auxiliary drying cylinder situated at

the wet end of the range of paper-drying cylinders, so that the felt is dried immediately before it comes in contact with the paper.—J. F. B.

Translucent paper; Reinforced— and process for making same. E. Bellan, Paris. Eng. Pat. 113,062, July 14, 1917. (Appl. No. 10,233 of 1917.) Under Int. Conv., Apr. 20, 1917.

REINFORCED translucent paper is manufactured from two sheets of paper between which is fixed a reinforcement of textile or metallic thread; the adhesive which is employed for sticking the sheets together contains an oily or fatty body, e.g., 30–40% of linseed oil, in such proportion that the adhesive and translucent effects are produced in one operation.—J. F. B.

Vegetable substances; Method of treating— for the recovery of their values. M. W. Marsden, Logan Station, Pa. U.S. Pat. 1,251,261, Dec. 25, 1917. Date of appl., Apr. 26, 1916.

FIBROUS vegetable material is cleansed and softened by immersion, then subjected to squeezing in order to loosen the fibres lengthwise and crush the material; the crushed mass is washed with the use of steam and leached while open to the atmosphere, to remove the extractive matter. After thorough rinsing, the material is digested until the fibres are reduced to the uniformity required for paper-making.—J. F. B.

Sulphite acid liquor and the like; Means for making—. G. D. Jessen, New York. U.S. Pat. 1,251,533, Jan. 1, 1918. Date of appl., Mar. 24, 1917.

THE apparatus comprises a pair of towers each having near the lower end a partition supporting blocks of acid-proof material to retard the downward flow of liquor, and some distance above this partition a second partition supporting a layer of limestone. Water is supplied to the upper ends of the towers and sulphur dioxide gas to the lower ends. Gas-outlet pipes at the upper ends of the towers are connected with a pipe through which the gas can be supplied again to the lower ends of the towers. The liquor withdrawn from the lower ends of the towers is returned to the towers, below the partition supporting the limestone, for re-treatment.

Ligninsulphonic acid or its salts; Method of preparing nitroso compounds from—. E. Oman, Stockholm. Eng. Pat. 103,653, Jan. 4, 1917. (Appl. No. 204 of 1917.) Under Int. Conv., Jan. 14, 1916.

SODIUM ligninsulphonate, 100 grms. of 60% purity, obtained by saturating sulphite-cellulose waste lye with sodium chloride, is dissolved in 600 grms. of water; a solution of 60 grms. of sodium nitrite in 100 of water is added, the mixture is cooled with ice and treated with a solution of 60 grms. of concentrated sulphuric acid in 400 of water. After some hours the nitroso compound is separated by the addition of salt and purified by washing with a saturated solution of sodium chloride. If desired, the free ligninsulphonic acid, precipitated by hydrochloric acid, may be dissolved in water and treated for the production of the nitroso compound. An impure nitroso compound may be prepared direct from the sulphite waste lye. The product has a yellowish-brown colour and may be used as a colouring matter. (See also this J., 1918, 121 A.)—J. F. B.

Wood pulp sulphite plants; Process of treating by-product liquors from—. C. Marchand, Kimberly, Wis., Assignor to The Marchand Process Co., Chicago, Ill. U.S. Pats. (A) 1,253,853 and (B) 1,253,854, Jan. 15, 1917. Dates of appl., (A) Nov. 26, 1915, and (B) Aug. 14, 1916. Renewed Nov. 19, 1917.

(A) SULPHITE wood pulp waste liquor is treated

in a tank with sulphuric acid to convert the sulphites into sulphates and precipitate the lime; a predetermined quantity of the treated liquor is discharged into a preliminary heater and charge-measurer, where it is maintained at a temperature below boiling, and subsequently discharged into an evaporator. The liquor is evaporated under vacuum to remove a portion of the sulphur dioxide and is then passed to a second evaporator at a lower temperature and higher vacuum until most of the sulphur dioxide is vaporised. The vapour from the evaporators is absorbed in a reagent to produce a sulphite and the concentrated liquor is treated in a tank with an oxidising agent to produce sulphuric acid and then fermented. (B) Waste sulphite liquor is treated to convert the sulphites into the corresponding chlorides and sulphur dioxide. The latter is expelled, the residue fermented, the alcohol distilled off, the residual liquid evaporated, the solid residue incinerated, and the chlorides are recovered by repeated crystallisation.—J. F. B.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid situation in the United States. L. B. Skinner. Met. and Chem. Eng., 1918, 18, 82–85.

PRIOR to the war sulphuric acid in the United States was made exclusively from the gases produced by roasting zinc blende and pyrites or by the blast-furnace treatment of Tennessee copper ores. The demand for acid during the war has stimulated production which, however, has never yet met all requirements. To increase the output from zinc-acid plants brimstone has been added to the ore fed into the burners (Hegeler kilns) whereby the chamber output has been increased 20%. Australian concentrates are being used and may continue to be used after the war. The production from plants now using or which previously used pyrites has also increased, to some extent due to the substitution of brimstone for the now scarcer Spanish ore. There is, however, no commercial advantage, even under present conditions, in doing this. The development of the contact processes in America has been restricted by the onerous conditions of licences and royalties imposed by European patent owners. When fine concentrates are used, the roaster gases carry much undesirable dust. The Cottrell process has failed to work satisfactorily under the very severe practical conditions of acid plants where it has been tried. The lead tower in chamber plants is giving way to cheaper masonry designs and the stoneware fittings to silicon-iron castings. The increased demand for sulphuric acid has been due to the production of explosives and to the demand of oil refineries largely caused by the growth of use of motor vehicles under war conditions. The quantity available for the manufacture of fertilisers has been insufficient for the demand. In the future, acid production will be an adjunct to the metallurgical industry. Pyrites and also brimstone burning for acid will probably decline. Much will depend on the transport facilities which should be arranged in the national interest to favour the utilisation of the waste and noxious gases produced by smelting works.—H. J. H.

Selenium in sulphuric acid; Detection of—. L. P. J. Palet. Ann. Chim. Analyt., 1918, 23, 25–26.

If a small crystal of aspidospermine is added to a few drops of sulphuric acid containing selenium, and the mixture then heated until fumes appear, the crystal, and afterwards the whole mixture, is coloured an intense violet. A coloration is not

obtained in the absence of selenium, but a red coloration develops if the acid contains an oxidising substance such as lead peroxide or potassium chlorate.—W. P. S.

Phosphorous, hypophosphoric, and phosphoric acids in mixtures; Estimation of—. R. G. van Name and W. J. Huff. Amer. J. Sci., 1918, 45, 91–102.

A METHOD for the estimation of phosphorous acid in presence of hypophosphoric acid depends on the reactivity of the former towards iodine in presence of disodium hydrogen phosphate, which is added in sufficient quantity to leave the solution alkaline when the reaction is completed. The solution containing the phosphorous acid is made approximately neutral, the requisite quantity of disodium hydrogen phosphate added, followed by the addition of an excess of a standard solution of iodine. The solution is then left in the dark for at least two hours and the residual iodine determined by titration with thiosulphate after the solution has been acidified with phosphoric acid. The method gives accurate and concordant results and is a considerable improvement on Sievert's method (this J., 1909, 1169) in which the reaction takes place in presence of potassium bicarbonate. According to the authors' experiments this method always gives results which are somewhat too high. The new method may also be used in the estimation of hypophosphoric acid if this is previously hydrolysed by heating the solution at 100° C. in presence of hydrochloric acid. The reaction takes place according to the equation: $H_4P_2O_6 + H_2O = H_3PO_3 + H_2PO_4$. Phosphorous and hypophosphoric acids, when present in the same solution, may be estimated by the application of the iodometric method before and after hydrolysis. Solutions containing phosphorous, hypophosphoric, and phosphoric acids may also be examined by the method, the iodine absorption being determined before and after hydrolysis and the total phosphoric acid determined in the oxidised solution. A modification of Kühling's permanganate method (this J., 1900, 1149) for the estimation of phosphorous acid is also described, zinc sulphate being added to prevent the solution from becoming alkaline. The mixture, to which an excess of standard permanganate is added, is heated for 90 minutes in a steam bath, cooled, and treated with an acidified solution of potassium iodide, the liberated iodine being titrated with thiosulphate. The relation between the permanganate and thiosulphate solutions is determined by a blank experiment.—H. M. D.

Hypophosphoric acid solutions; Rate of hydrolysis and electrical conductivity of—. R. G. van Name and W. J. Huff. Amer. J. Sci., 1918, 45, 103–118.

MEASUREMENTS have been made of the velocity of hydrolysis of hypophosphoric acid in aqueous solutions at different temperatures. Acid solutions of hypophosphates cannot be boiled without appreciable loss by hydrolysis. (See also J. Chem. Soc., Mar., 1918.)—H. M. D.

Lead acetate; Solubility of— in water. Y. Osaka and R. Hara. Mem. Coll. Sci., Kyoto, 1917, 2, 147–150.

THE solubility of lead acetate in pure water has been found to be 51.38 parts per 100 of water at 25°, 87.77 at 35°, and 154.25 at 45° C. (See also J. Chem. Soc., Mar., 1918.)—H. M. D.

Metaphosphoric acid; Thermal dissociation of—. D. Balarew. Z. anorg. Chem., 1918, 102, 34–40.

By the dehydration of orthophosphoric acid by

heat, metaphosphoric acid is formed and, when subjected to prolonged heating, volatilises slowly. (See also J. Chem. Soc., Mar., 1918.)—E. H. R.

Polish: Italian leucitic lavas a source of —.
H. S. Washington. Met. and Chem. Eng., 1918, 18, 65–71.

ATTENTION is drawn to the leucitic lavas of the Italian volcanoes which form perhaps the most extensive accumulation of potash-containing igneous rocks on the earth's surface. Leucite (KAlSi_2O_6) contains theoretically 21.5% K_2O and is readily decomposed by acids, whereas orthoclase feldspar contains only 16.9% K_2O in a form extremely resistant to processes of extraction. The leucite trachytes—essentially soda feldspar and leucite—are the richest of the lavas and contain on an average about 10% K_2O , while the average K_2O content of 44 lavas analysed, including non-leucitic kinds, was 8.31%. Seven Italian volcanoes characterised by leucitic lavas have been examined geologically and chemically, their cubical content calculated and probable quantity of K_2O therein. They are Bolsena, Vico Volcano, Bracciano, Alban Hills, Hermian Volcanoes, Rocca Monfina, and Vesuvius—the only one still active. It is estimated that they contain 105,340 million metric tons of leucitic lavas containing between 7.5% and 9% K_2O , or 8786 million tons of K_2O . The situations are favourable to exploitation and transport facilities are good.—H. J. H.

Oceanic salts: A complete review of solutions of —. III. E. Jänecke. Z. anorg. Chem., 1918, 102, 41–65.

The effect of water or, which amounts to the same thing, sodium chloride, as a variable on the equilibrium diagram for the system $(\text{Na}_2\text{Mg})(\text{Cl}_2, \text{SO}_4)$ is considered with respect to the simple salts MgCl_2 , 2KCl , Na_2SO_4 , represented by the corners of a triangle in the original diagram, and also with respect to the three double systems represented by the sides of the triangle. (See also J. Chem. Soc., 1918.)—E. H. R.

Bleaching powder: The best proportions for the manufacture of — in mechanical apparatus.
H. Ditz. Z. anorg. Chem., 1918, 102, 66–80.

THE quality of the bleaching powder produced in mechanically operated plant is influenced by the concentration of chlorine in the incoming gas mixture and by the presence of water. The most favourable chlorine concentration is 10–12% to obtain a bleaching powder containing 36–37% of available chlorine, the diluting air serving to moderate the reaction velocity and to conduct away the heat of reaction. The gas mixture must be dried by passing through sulphuric acid, a wet gas causing rise of temperature and consequent decomposition of the bleaching powder. The slaked lime used, however, should contain 5–6% excess (hygroscopic) moisture (see Schütz, this J., 1917, 546.) The function of this water appears to be to cool the reaction mixture by its own evaporation. Supposing the air leaving the plant at 10°C . to be saturated with water vapour, a simple calculation shows that about 21% of the heat produced by the reaction is carried off by this means, the remainder being lost by conduction and radiation. The 5–6% hygroscopic moisture in the lime is not sufficient, however, to saturate the air, but there is sufficient water set free by the first phase of the reaction, namely

to make up the deficiency. If, however, the lime were dry at the start, water would be obtained from the above basic compound, bringing about its decomposition with liberation of chlorine.

The initial water in the lime therefore serves to prevent this secondary decomposition. It appears possible that, by using lime containing up to 8–9% excess water at the start, a better bleaching powder containing up to 39–40% of available chlorine might be obtained, but apparently with so much water the lime is liable to form lumps into which the chlorine cannot permeate. The conditions obtaining in the chamber process are different, since here the lime is not in motion. If diluted Deacon chlorine is used, the gas must be dried, according to Ilurter. Carbon dioxide appears to have a more deleterious effect in the mechanical apparatus than in the chamber process. The decomposition of bleaching powder by carbon dioxide is favoured by high temperature and the presence of water, and these conditions obtain in the higher tubes of the mechanical apparatus.—E. H. R.

Boron: Preparation of amorphous —. W. Kroll. Z. anorg. Chem., 1918, 102, 1–33.

THE most satisfactory method of reducing boron trioxide to amorphous boron is the magnesium-thermite process with addition of sulphur. The reaction mixture consists of 1 part each of magnesium and boron trioxide and 0.8 part of flowers of sulphur, the reaction being carried out in a fireclay or magnesia crucible. The product contains over 90% boron, the chief impurity being magnesium boride. The purest form of boron was obtained by subjecting a mixture of boron trichloride and hydrogen to the action of a high-tension arc, using platinumised copper electrodes. The process is impracticable on a large scale. A sample made by this process contained 98.8% boron and had the sp.gr. 1.731. By heating boric acid with magnesium nitride, a boron nitride was obtained having the composition B_3N , whilst BN was obtained by the action of calcium cyanide on boron trioxide. (See also J. Chem. Soc., Mar., 1918.)—E. H. R.

PATENTS.

Sulphuric acid: Process of manufacturing —.
M. L. Hanahan, Dothan, Ala. U.S. Pat. 1,253,238, Jan. 15, 1918. Date of appl., Mar. 2, 1917.

IN a sulphuric acid plant a dust chamber is provided, communicating with the pyrites furnace or roaster, and sulphur dioxide is produced in the dust chamber by burning sulphur or sulphur-containing material.—B. V. S.

Nitric acid from ammonia; Process for making —.
A. A. Wells, Caldwell, N.J., Assignor to Ellis-Foster Co. U.S. Pat. 1,252,976, Jan. 8, 1918. Date of appl., Mar. 7, 1917.

IN a process of oxidising ammonia to produce oxides of nitrogen, with a minimum formation of nitrogen, a mixture of ammonia and air is passed through a heated chamber the interior surfaces of which are coated with catalytic material having oxidising properties. A series of superposed chambers or compartments may be employed in which the gaseous mixture is caused to pass through layers of the catalytic material in alternate compartments. In this case the more highly oxidised gas product and that from less advanced stages of reaction are caused to traverse adjacent chambers to effect an interchange of heat.

—W. E. F. P.

Sulphuric anhydride; Apparatus for the catalytic preparation of —. W. J. Mellorsh-Jackson. London. From Bombrini Parodi-Delfino, Rome. Eng. Pat. 113,017, Mar. 1, 1917. (Appl. No. 3054 of 1917.)

THE reacting gases pass into the reaction chambers (A_1 , A_2 , and A_3) through the valve, f , chamber, g

pipes, h , and chamber, i , and the waste gases pass out through b and c to one or both of the valves, m and e . By regulation of these two valves and thus of the amount of waste gases passing through d , the heating of the gases in pipes, h , is controlled.—B. V. S.

Chemical reactions [synthesis of ammonia]; Process and apparatus for accelerating —. W. A. Schmidt, Assignor to International Precipitation Co., Los Angeles, Cal. U.S. Pat. 1,252,726, Jan. 8, 1918. Date of appl., June 22, 1916.

NITROGEN and hydrogen are caused to combine in a reaction chamber to form ammonia gas, which passes with the uncombined nitrogen and hydrogen to another chamber containing a substance which combines with ammonia to form a cloud of suspended particles. The suspended particles are precipitated by the application of an electrical difference of potential, and deposited, and the uncombined nitrogen and hydrogen are returned to the reaction chamber for further treatment.

—W. F. F.

Polash and other values; Process for extracting — from tobacco. W. H. Kennedy and G. E. Bailey, Los Angeles, Cal., Assignors to American Safety Explosives Co. U.S. Pat. 1,253,497, Jan. 15, 1918. Date of appl., Mar. 19, 1917.

TOBACCO is treated with alcohol and the solution removed. The residue is distilled to extract gums and resins, and the final residue roasted with charcoal so as to produce potassium carbonate, which is removed by leaching with hot water.

—W. F. F.

Polash extraction [from felspar]. E. L. Anderson, Pittsburgh, Pa. U.S. Pat. 1,253,560, Jan. 15, 1918. Date of appl., Apr. 8, 1916.

FELSPAR or the like is ground and mixed with an insoluble electrically conducting material such as

carbon. The mixture is electrolysed in a solution containing a substance which combines with the potash to convert it into a form which is easily electrolysed.—W. F. F.

Aluminous compounds; Production of —. W. B. Llewellyn, H. Spence, and P. Spence and Sons, Ltd., Manchester. Eng. Pat. 112,881, May 11, 1917. (Appl. No. 6687 of 1917.)

SMALL lumps of bauxite, e.g., such as will pass through a mesh of $\frac{1}{2}$ -in. or $\frac{3}{4}$ -in., are placed in suitable vessels and solutions of sulphuric acid or of aluminium sulphate (containing a higher ratio of SO_3 to Al_2O_3 than is desired) obtained from previous operations are caused to circulate through the mass. The vessels are fitted with false bottoms through which the liquor percolates, the bauxite acting as a filter for suspended particles. The bauxite is preferably treated first with a solution of aluminium sulphate containing little or no free acid, then with solutions containing progressively more free acid, and finally with weak liquors and water, these last being used to dilute the sulphuric acid for further operations. Before treatment, the bauxite is usually ignited at about a low red heat, although this is not necessary if it contains a very high percentage of silica. By adopting the above procedure, extraction of the bauxite is more complete than by the old method; cost of powdering the bauxite is avoided; varieties of high silica content can be economically dealt with, in fact, are preferable; filter-pressing of the residue is avoided; solutions in a highly basic condition can readily be obtained without increased loss of alumina in the residue; and the solutions obtained are substantially free from sediment. The solutions may be purified from iron or converted into saleable form, or may be used for preparing other compounds of aluminium. The bauxite may be placed in vessels together with calcined underground shales and the process continued as described in Eng. Pats. 3805 and 22,950 of 1912 (this J., 1913, 363, 1066).—L. A. C.

Alumina; Art of producing —. M. Barnett and L. Burgess, New York. U.S. Pat. 1,252,384, Jan. 8, 1918. Date of appl., Dec. 18, 1916.

A SOLUTION of aluminium sulphate is evaporated until the boiling point of the liquid is just below $120^\circ C.$, after which the heating is continued, with agitation, until the anhydrous sulphate is obtained. The latter is then decomposed by heating at 550° – $650^\circ C.$, alumina being produced and the sulphur recovered as sulphuric acid.—W. E. F. P.

Aluminium sulphate [from solutions of aluminium sulphate containing iron]; Art of producing —. M. Barnett and L. Burgess, New York. U.S. Pat. 1,252,648, Jan. 8, 1918. Date of appl., Dec. 18, 1916.

THE iron in solution is oxidised by means of ozone or ozonised air, then precipitated as hydroxide and separated by filtration.—W. E. F. P.

Aluminium nitride; Art of producing —. M. Barnett and L. Burgess, New York. U.S. Pat. 1,252,649, Jan. 8, 1918. Date of appl., June 1, 1917.

ALUMINIUM carbide is treated with nitrogen at 900° – $1200^\circ C.$, and the product allowed to cool in the gas.—W. E. F. P.

Sodium ferrocyanide; Process of making —. A. R. Tillinghast, Assignor to Semet-Solvay Co., Solvay, N.Y. U.S. Pats. (A) 1,252,741 and (B) 1,252,742, Jan. 8, 1918. Dates of appl., Dec. 20, 1916 and Jan. 10, 1917.

(A) IN the recovery of cyanogen from coal gas, after the removal of ammonia, the gas is scrubbed with a solution of soda ash containing ferrous

carbonate in suspension. The scrubbing medium is then treated with milk of lime and filtered, the solution being concentrated for the recovery of sodium ferrocyanide by crystallisation. (B) The mother liquor from the crystallisation (containing sodium ferrocyanide, carbonate, and hydroxide) is treated with ferrous sulphate and the product employed for scrubbing a further quantity of gas.—W. E. F. P.

Alkali perborates; Process of making——. O. Liebknecht, Frankfort, Germany. Assignor to The Roessler and Hasslacher Chemical Co., New York. U.S. Pat. 1,253,060, Jan. 8, 1918. Date of appl., May 31, 1916.

A SOLUTION of alkali borate and alkali carbonate, kept saturated with both salts, is electrolysed with a current density approximately the same at both cathode and anode.—B. V. S.

Reducing agent [containing ferrous and calcium sulphides] and method of producing same. C. S. Bradley, New York. U.S. Pat. 1,253,775, Jan. 15, 1918. Date of appl., Mar. 13, 1913. Renewed June 7, 1917.

THE reducing agent is a mixture of calcium and ferrous sulphides, containing also calcium sulphate, produced by heating together to a low red heat pyrites and burnt lime.—B. V. S.

Radio-active mineral-water salts; Method of manufacturing——. J. H. Jacobsen, Herloev, Denmark. U.S. Pat. 1,253,830, Jan. 15, 1918. Date of appl., May 8, 1915.

A SOLUTION of a radium salt and a salt of the mineral water which does not precipitate radium is evaporated to dryness. The resulting salt is freed from water of crystallisation and pulverised with the other salt constituents of the mineral water.—B. V. S.

Alunite; Separation of——*from associated rock and/or gangue*. C. F. Hagedorn, Chicago, Ill., Assignor to Mineral Products Corporation, New York. U.S. Pats. (A) 1,253,590 and (B) 1,253,591, Jan. 15, 1918. Dates of appl., Nov. 13, 1915, and Oct. 26, 1917.

(A) To separate rhyolite or the associated rock or gangue from alunite, the mixture is crushed to one-quarter inch mesh and calcined or roasted in a rotary inclined kiln at a low temperature and at such a rate that the specific gravity of the alunite is lowered, but that of the rock or gangue is not affected, and volatilisation of the potash does not take place. The soluble potash salt is extracted and the rock or gangue finally separated by gravity from the undissolved calcined alunite. (B) Silica or silicious minerals such as rhyolite or the like are separated from alunite by roasting or calcining the mixture in a rotary kiln by means of an injected fuel not containing silicon. The silicious material is then separated from the calcined alunite.—W. F. P.

Borosilicates; Manufacture of——. R. Boehringer, Newark, N.J., U.S.A. Eng. Pat. 104,008, Feb. 9, 1917. (Appl. No. 2003 of 1917.) Under Int. Conv., Oct. 26, 1915.

SEE U.S. Pat. 1,205,509 of 1916; this J., 1917, 83.

Aluminium chloride; Art of producing——. Standard Oil Co., Assignees of M. Barnett and L. Burgess, New York. Eng. Pat. 109,790, July 23, 1917. (Appl. No. 10,554 of 1917.) Under Int. Conv., Aug. 11, 1916.

SEE U.S. Pat. 1,218,588 of 1917; this J., 1917, 456.

Alkali perborates; Process of making——. O. Liebknecht, Frankfort, Germany. Assignor to The Roessler and Hasslacher Chemical Co. U.S. Pat. 1,253,061, Jan. 8, 1918. Date of appl., May 31, 1916.

SEE Eng. Pat. 101,620 of 1916; this J., 1917, 137.

Crude ammoniac; Treatment of the residue from gas purification known as——. L. C. Bonneau, St. Denis, and V. E. Hasenfratz, Levallois-Perret, France. U.S. Pat. 1,253,571, Jan. 15, 1918. Date of appl., Apr. 21, 1914.

SEE Fr. Pat. 468,535 of 1913; this J., 1914, 962.

Nitrogen; Process of producing——*simultaneously with oxides of nitrogen*. M. Rohmer, Gersthofen. Assignor to Farbwerke vorm. Meister, Lucius, u. Brüning, Höchst, Germany. U.S. Pat. 1,253,534, Jan. 15, 1918. Date of appl., Apr. 16, 1914.

SEE Addition of Apr. 17, 1914, to Fr. Pat. 453,845 of 1913; this J., 1915, 552.

Hydrogen; Manufacture of pure——. E. B. Maxted, Walsall. U.S. Pat. 1,253,622, Jan. 15, 1918. Date of appl., July 17, 1916.

SEE Eng. Pat. 12,698 of 1915; this J., 1916, 1060.

Means for making sulphite acid liquor and the like. U.S. Pat. 1,251,533. See V.

VIII.—GLASS; CERAMICS.

PATENTS.

Furnace-lining material and the process of producing same. F. A. Jones, Lakewood, Ohio. U.S. Pat. 1,251,535, Jan. 1, 1918. Date of appl., Nov. 15, 1915.

A MATERIAL containing magnesium oxide, e.g., dolomite, is crushed so that the particles will pass through a screen of $\frac{1}{2}$ in. mesh but not through one of $\frac{3}{4}$ in. mesh. The granulated material is mixed with a wet paste containing a substance which is not acted on by moisture, e.g., furnace flue dust, and the mixture is heated until the dolomite is calcined and the fine dust adheres to the surface of the calcined dolomite.—J. F. B.

Kiln. U.S. Pat. 1,251,333. See I.

IX.—BUILDING MATERIALS.

Cement; The effect of calcium sulphate on——. J. C. Witt and F. D. Reyes. Philippine J. Sci., 1917, 12 A, 133—143.

THE addition of calcium sulphate, either as gypsum or plaster of Paris, to cement, to the extent of 1.5 to 2% SO_3 , had the effect of retarding the setting time without decreasing the tensile strength; further additions again accelerated the time of setting and also caused a decrease in tensile strength. Usually the loss of strength was noticeable with anything higher than 2% SO_3 , but with certain samples there was no loss until about 5% SO_3 was present. The percentage loss was greater with mortar than with the neat cement, and, with the latter, decreased after seven days. The soundness of the cement (five hours in steam) was unaffected by any addition investigated, i.e., up to about 10% SO_3 . The tests on the strength of the cements have so far been carried out over a period extending to ninety days, but additional briquettes have been made for testing over periods ranging from six months to five years. The influence of carbon dioxide on the setting time was tested by the method of Hentschel (this J., 1912, 387), and no relation between the SO_3 content and the effect of exposure to carbon dioxide was apparent. It

was also shown that the formation of alkali carbonates is not an important factor in the change of physical properties of cement during storage.

—L. A. C.

PATENTS.

Concrete and the like; Machine for mixing —. Ransome Concrete Machinery Co., New York, Assignees of A. W. Ransome, Plainfield, N.J.. U.S.A. Eng. Pat. 107,575, Mar. 28, 1917. (Appl. No. 4505 of 1917.) Under Int. Conv., June 30, 1916.

A ROTATING drum, A, is provided with tapering blades, B, resembling propeller blades, attached to the end wall at B', and extending obliquely to

points near the axis. Blades, D, of stirrup shape, tapering towards both extremities, are secured to the casing at G' and H'. Further blades, C, are attached at their two ends to the inner extremity and the middle portion respectively of two adjacent blades, D, as shown, in such a way that they are substantially horizontal at their lowest position. The material to be mixed is fed into the opening, A', on to the blades, B, and part of this material falls from the narrow inner ends on to the blades, C, and passes thence to the scoop blades, D. A complex movement is given to the materials during mixing, and the mixture is discharged at the opening, A'', by inserting a suitable shoot to catch it as it falls from the blades, D.—W. F. F.

Road-surfacing material; Process of producing —. G. Ross, Kansas City, Mo. U.S. Pat. 1,252,722, Jan. 8, 1918. Date of appl., July 21, 1917.

EARTHY material is mixed with water to produce a thin mud, and bitumen and a solvent for the latter added, the mixture being agitated. Crushed rock, gravel, or sand is then added and the mixture compacted on a roadway. In a modification, the earthy material, water, and bitumen are mixed and spread on the road, and after drying, the bitumen solvent is applied to the surface.—W. F. F.

Wood and other cellulose-containing materials; Art of treating —. G. W. Herbein, San Francisco, Cal., U.S.A. Eng. Pat. 113,209, June 1, 1917. (Appl. No. 7869 of 1917.)

SEE U.S. Pat. 1,235,895 of 1917; this J., 1917, 1014.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Steel projectiles; Principal defects in — and method of avoiding them. G. Sirovich. *Annali Chim. Appl.*, 1917, 8, 122—158.

IN Italy hard steel intended for certain munition purposes is required to have a tensile strength exceeding 80 kilos. per sq. mm. In the case of ordinary steels poor in manganese and silicon, an increase in the carbon content beyond a certain limit increases the hardness but reduces the tensile strength. Hence to produce a steel of high strength, which can also be worked readily, it is necessary to raise the proportion of manganese, whilst restricting that of the carbon. Steel rich in manganese shows less segregation than a corresponding steel of low manganese content; it also is less liable to deterioration due to overheating during heat treatment. Common steels with high manganese content are largely composed of a series of mixed crystals which solidify within narrow limits of temperature, and such steel is not liable to deteriorate during heat treatment. In Italy, steel for projectiles is made almost exclusively in the basic Martin furnace. In addition to pure aluminium, alloys of iron with various elements are used for the de-oxidation of the steel, and especially ferro-manganese with 50% Mn, or ferro-silicon with 50% Si. The de-oxidation of steel with high manganese content is more troublesome than that of steel poor in manganese, and care is required to prevent the occlusion of products which are not able to reach the surface before complete solidification of the ingot. In general, the main difficulty in the manufacture and working of hard steel is the presence of minute particles of slag ("sonims"), such as silica, iron silicate, and manganese silicate. The use of ferro-silicon gives a less oxidised melt, and produces phases in which basic elements predominate to a less extent than when manganese alone is used. It is practically impossible to eliminate "sonims" from steel with high manganese content, but their occlusion may be restricted by regulating the reactions which take place in the production of the steel.—C. A. M.

Silicon; Determination of — in ferrosilicon. P. Nicolardot and J. Koenig. *Rev. Mét.*, 1917, 14, 772—775.

0.170 GRM. of powdered ferrosilicon is mixed with 3 grms. of soda-nitre mixture (5:2) and transferred to a platinum crucible in which 2 grms. of the fusion mixture has been melted, so as to protect the metal. Heat is applied gradually until a violent reaction sets in; the heat is then raised until quiet fusion is attained (10 minutes). The subsequent operations are the same as for the determination of silica in silicates, with the precautions recommended in the following abstract.—W. R. S.

Silica; Filtration of — [in analysis]. P. Nicolardot and J. Koenig. *Rev. Mét.*, 1917, 14, 767—771.

THE experiments were undertaken in order to test new filters made in France (Brunin and Durieux brands), taking into account Le Chatelier's views according to which silica separated by an acid is quite insoluble but cannot be quantitatively recovered because, being in a state of extreme subdivision, it passes through the filter; the effect of repeated evaporation may therefore be regarded as to agglomerate the silica rather than to render it insoluble. The first half at least of the filtrate should always be poured back through the filter; only the filtrate itself need be evaporated a second time, not the washings. The quantity of silica lost is independent of the absolute quantity

present; hence the relative error is decreased by operating on a larger amount of material. The quality and kind of filter paper was found not to influence the results, provided a good homogeneous paper was used. Two evaporations with hydrochloric acid in a porcelain dish, followed by a single filtration, the decanted solution being again poured through the filter, were found to give sufficiently accurate results in a reasonably short time.—W. R. S.

[Gold] ores; Cyaniding graphitic.—P. T. Brühl. Eng. and Min. J., 1918, 105, 197.

The recovery of gold from graphitic ores by cyaniding does not as a rule exceed 50%, the gold being prematurely precipitated from solution by the graphite. By submitting the ore pulp to flotation, the graphite passes into the froth together with any auriferous pyrite and mispickel. The flotation concentrate is roasted, added to the tailing, and the product cyanided. The tailings from the flotation process are relatively free from carbonaceous matter and pass to the cyanide slimes plant.—W. R. S.

Gold and silver; Metallurgy of.—[in 1917]. H. A. Megraw. Eng. and Min. J., 1918, 105, 102—104.

No development of fundamental importance took place in the metallurgy of gold; existing processes were improved, and economies in working aimed at. The increased price of silver stimulated production, though the Mexican output was only about 40% of the normal figure because of unsettled political conditions and the stoppage of supply of German cyanide. At Pachuca, the substitution of flotation for cyaniding gave promising results, installation and working costs being smaller than for the cyanide process. The flotation concentrate (argenteite) is smelted or cyanided. Flotation has also been introduced at Cobalt, where it is a valuable adjunct to concentration and cyaniding, adding 10% and more to the recovery, at a cost of less than 20c. per ton. In crushing the ores, the tendency is to replace stamps by ball mills.

—W. R. S.

Silver; Rate of solution of.—in chromic acid. R. G. Van Name and J. U. Hill. Amer. J. Sci., 1918, 45, 51—58.

EXPERIMENTS on the rate of solution of silver in chromic acid solutions containing sulphuric acid show that there is an initial disturbance which is attributed to the physical state of the metal. The rates at which cadmium and silver dissolve become more nearly equal with diminishing sulphuric acid concentration. (See also J. Chem. Soc., March, 1918.)—H. M. D.

Copper; Metallurgy of.—[in the United States in 1917]. A. L. Walker. Eng. and Min. J., 1918, 105, 94—96.

ONE new plant was put in commission, viz., the New Cornelia Copper Co.'s leaching and electrolytic plant at Ajo, Ariz. The ore is leached with 3% sulphuric acid, and the latter regenerated; part of the regenerated solvent must be discarded, to prevent the accumulation of iron and aluminium. The Utah Copper Co. is installing a similar plant for the oxidised ores of Bingham, Utah. The ammonia leaching plants at Calumet and Kennecott (Alaska) are being greatly enlarged. Flotation for fines and slimes has now been introduced at all the large concentrating plants.—W. R. S.

Zinc; Metallurgy of.—[during 1917]. W. R. Ingalls. Eng. and Min. J., 1918, 105, 96—99.

At Bartlesville, Okla., a process is about to be put in operation which consists in distilling the roasted ore with a small proportion of fuel. The residue

rich in zinc and lead will be burned on Wetherill grates. Several large smelters have installed oxide plants to recover zinc from distillation residues. A 60% recovery can be made from residues containing 6% Zn without the use of any fuel other than that present in the residues. The manufacture of high-grade zinc dust, prepared by atomising the metal with compressed air, has been started by the Anaconda Copper Co., the New Jersey Zinc Co., and several other companies. Several new electrolytic extraction works started operations, but none attained large production. Much spelter was again refined by re-distillation, the refined metal containing as little as 0.10% Pb.

—W. R. S.

Lead; Metallurgy of.—[in 1917]. H. O. Hofman. Eng. and Min. J., 1918, 105, 93—94.

MIXED lead-zinc ores are being treated by sulphatizing roasting followed by leaching with sulphuric acid. The solution is purified, nearly neutralised, and electrolysed with lead anodes and aluminium cathodes; the yield up to the present is only 60%. A new smelting works started operation at Kellogg, Idaho; it comprises one Wedge roaster, 3 Dwight-Lloyd sintering machines, and 3 blast furnaces (48×180 in.). Leaching experiments at Kellogg (chloridising roast and leaching with acidulated brine) gave a yield of 85—95% lead and 80—90% silver. An automatic bag filter is in operation at Depue, Ill. The bags of each division are alternately inflated and deflated as well as subjected to an up-and-down and undulating motion. The cleaning of the cloth is thus accelerated and the filtering capacity increased.—W. R. S.

Mercury; Metallurgy of.—[in 1917]. M. Innes. Eng. and Min. J., 1918, 105, 110—111.

THE production of mercury in the United States has been steadily declining for 40 years, due chiefly to inability to compete with the European output, and to the poor grade of ore now mined in California, the average recovery being 6 lb. per ton of ore. The chimney losses of the Scott furnace (which produces 95% of the metal in California) were found to be negligible. In spite of its rather high first cost and moderate capacity, this furnace has the advantage of general efficiency and low fuel cost, and treats coarse (2-in. mesh) ore, thus avoiding the drawbacks of fine grinding. A new rotary furnace of the cement-kiln type, which is being installed by the New Idria Co., will, it is expected, handle an increased tonnage at lower cost.—W. R. S.

Flotation; Progress of.—in 1917. H. A. Megraw. Eng. and Min. J., 1918, 105, 99—102.

IN the Joplin district (Missouri), the use of a mixture of turpentine and rosin was tried; 1—5 lb. of mixture (rosin 20—30, turpentine 80—70%) per ton of ore assaying 1—2% of zinc in an acid pulp (ratio 5:1), gave rough concentrates containing 37.66% of zinc, the recovery being 50—80%. Cold solutions give a higher recovery than warm, but the grade of product is not so good. The introduction of flotation in Missouri lead milling has not greatly altered local practice. It is applied to galena finer than 200-mesh, as the tables deal efficiently with coarser sizes. The frothing agent is creosote; the tailing from the first treatment is re-treated, giving final tailings. At Humboldt, Ariz., the advent of flotation rendered treatment of much poor copper ore possible, while improving the recovery in concentration and the grade of concentrate. With clean sulphides, the recovery sometimes reaches 95%. The Murex process is used at Darwin, Cal., for the concentration of lead carbonate ores, at a cost of \$1.78 per ton. In this process a magnetic material is mixed with oil to form a paint, which is agitated with the ore to be

treated. The paint adheres to the particles of valuable mineral and the latter are recovered by means of a magnetic separator. The advantage of the process is that the ore need only be ground fine enough to liberate the particles of ore from gangue.—W. R. S.

Flotation: Effect of addition agents in —. II. M. H. Thornberry and H. T. Mann. *Met. and Chem. Eng.*, 1918, 18, 71—77. (See also this J., 1918, 93 A.)

THE experiments recorded in the previous paper have been extended to include hydroxides and nitrates. The hydroxides employed—alkalis and alkaline earths—behaved on the whole similarly to the sulphates, the relative extractions being practically the same, but the grade of concentrate slightly lower. Calcium hydroxide had most effect on the character of the froth. The results in presence of nitrates depended largely on the oil used and showed great divergence. With the flotation oil No. 1, the extraction was scarcely altered, while the grade of concentrate was lowered about 17%. With the Naval Stores oil No. 17 and with cresylic acid, the extraction was lowered slightly, but the grade of concentrate was raised slightly with the latter and lowered with the former. Mercury and uranyl nitrates were deleterious, but most of all cadmium nitrate. Nitrates exerted considerable effect on the character of the froth. Nitric acid caused such copious frothing that the total quantity of oil could not be added, and the experiments with it had to be abandoned.

—H. J. H.

Tellurium and aluminium; Metallographic investigation of the system —. M. Chikashigi and J. Nosi. *Mem. Coll. Sci.*, Kyoto, 1917, 2, 227—232.

ALUMINIUM and tellurium form the compounds Al_2Te_3 and Al_3Te_2 . The reaction which occurs when aluminium and tellurium are heated together is very violent, and in the case of mixtures which contain 50 to 100% Te it is advisable to melt the tellurium and add the aluminium in small portions at a time. The compound, Al_2Te_3 , melts at 895° C. and forms mixed crystals with tellurium which exist in two different forms. The eutectic points at 414° and 621° C. correspond with 2.8 and 97% Al respectively. Conglomerates which consist of the second eutectic mixture and aluminium or the telluride, Al_3Te_2 , undergo transformation when the temperature falls to 551° C., with the formation of Al_2Te_3 . Both compounds are decomposed by water with the liberation of hydrogen telluride. (See also J. Chem. Soc., Mar., 1918.)—H. M. D.

Selenium and antimony; Metallographic investigation of the system —. M. Chikashigi and M. Fujita. *Mem. Coll. Sci.*, Kyoto, 1917, 2, 233—237.

ANTIMONY and selenium combine to form the selenide, Sb_2Se_3 , which melts at 572° C. The eutectic at 497° C. on the antimony side corresponds with 46.5% Se, and on the selenium side coincides with the freezing point of selenium. The results of micro- and thermal analyses are in agreement. (See also J. Chem. Soc., Mar., 1918.)

—H. M. D.

Cadmium and selenium; Metallographic investigation of the system —. M. Chikashigi and R. Hikosaka. *Mem. Coll. Sci.*, Kyoto, 1917, 2, 239—244.

WHEN cadmium and selenium are heated to a sufficiently high temperature, the compound, $CdSe$, is formed. The selenide is infusible up to 1350° C., and has sp.gr. 5.81 at 16° C. It does not dissolve in either of the molten elements, which

are themselves practically immiscible. The micro-structure of solidified melts is illustrated by photographs. (See also J. Chem. Soc., Mar., 1918.)

—H. M. D.

Zinc and selenium; Metallographic investigation of the system —. M. Chikashigi and R. Kurosawa. *Mem. Coll. Sci.*, Kyoto, 1917, 2, 245—248.

ZINC selenide, $ZnSe$, is formed when the two elements are heated together. It is infusible up to 1100° C., is brilliant yellow in colour and has sp.gr. 5.29 at 21° C. The two fused elements are immiscible with each other and with the compound. (See also J. Chem. Soc., Mar., 1918.)—H. M. D.

Aluminium and selenium; Metallographic investigation of the system —. M. Chikashigi and T. Aoki. *Mem. Coll. Sci.*, Kyoto, 1917, 2, 249—254.

ACCORDING to cooling curve observations, aluminium and selenium combine to form the compound Al_2Se_3 , which melts at about 950° C. This compound crystallises out from all fused mixtures of the two elements, and the eutectics correspond with pure aluminium and pure selenium respectively. Photomicrographs are reproduced which show the structure of the crystalline regulus obtained from various fused mixtures. The combination of aluminium with selenium is very violent and an explosion occurs readily when mixtures containing up to 80% Se are heated together. (See also J. Chem. Soc., Mar., 1918.)

—H. M. D.

Acidity determination in water, leach liquors, mine waters, etc. Rankin. See XXIII.

PATENTS.

Iron; Alloy of —. O. B. McMillin, Assignor to Pittsburgh Rolls Corporation, Pittsburgh, Pa. U.S. Pat. 1,252,596, Jan. 8, 1918. Date of appl., July 29, 1916. Renewed May 26, 1917.

THE alloy contains Si 0.25 to 1.0% (e.g., 0.5%), Cr 0.25 to 3.0% (1%), S 0.05 to 2.0% (0.12%), P 0.05 to 2.0% (0.08%), Mn 0.20 to 1.0% (0.3%), total C 1.5 to 3.5% (2.4%), Fe 95.6%.—T. H. B.

Steel; Welding and annealing high speed —. E. J. von Henke, Assignor to Thomson Electric Welding Co., Lynn, Mass. U.S. Pat. 1,252,746, Jan. 8, 1918. Date of appl., May 14, 1917.

AFTER electrically welding high-speed steel to machinery steel, the clamps on the high-speed steel are opened, and a heating current is immediately passed through from a point at the rear of the clamped section to and through the weld to bring the high-speed end of the tool to the desired annealing temperature.—T. H. B.

Steel, iron, or other magnetisable metal; Method of and means for indicating the condition of — during heat treatment. L. W. Wild and E. P. Barfield, London. Eng. Pat. 112,894, June 26, 1917. (Appl. No. 9170 of 1917.)

IN an apparatus for determining the temperature to which steel or other magnetic metal should be heated for hardening, tempering, and annealing, by means of an indication depending on the magnetic properties of the metal in a magnetic field at that temperature, the current which generates the field is also used to heat the metal. The metal is placed in a receptacle of silica, partly filled with a molten salt such as a mixture of potassium and sodium chlorides. A heating and magnetising coil is wound round the receptacle and connected to a pair of metal bands also surrounding it. The receptacle is placed in an outer vessel and the intermediate space filled with a

heat and electrical insulating substance, such as quartz powder. A secondary coil is wound on the outer vessel and two pairs of metal bands or clips are provided on this vessel to which the primary and secondary coils are connected. A galvanometer or other suitable recorder is included in the secondary circuit. When the metal reaches the temperature of decalescence it becomes non-magnetic and the consequent change in the magnetic field induces a current in the secondary coil which is indicated by the galvanometer or other apparatus.—W. F. F.

Manganese steel articles; Method of and apparatus for the heat treatment of—F. Schaffer, Leobersdorff, Austria. Eng. Pat. 112,986, Feb. 1, 1917. (Appl. No. 1655 of 1917.)

ARTICLES made of steel containing about 1% of carbon and more than 12% of manganese are heated to 1000°—1100° C. and cooled in accordance with a definite curve of time and temperature which will produce austenitic structure, and selected to obtain the structure and mechanical properties required. The cooling medium is applied by an automatic electrical device to the various parts in proportion to their area and the quantity of heat absorbed, so that the drop of temperature is uniform. The cooling is done automatically in stages each of which comprises cooling and subsequent equalising of differences in temperature.—W. R. S.

Furnace; Electrical — for hardening steel and the like. L. W. Wild and E. P. Barfield, London. Eng. Pat. 112,731, June 26, 1917. (Appl. No. 9169 of 1917.)

THE lower part of a crucible of silica or other suitable material to contain the molten salt bath in which the metal is immersed, is enclosed in a coil or winding and the ends of the coil are connected to metal bands around the crucible. The metal bands are connected to a source of electricity through similar metal bands on an outer casing or jacket, the crucible and jacket being separated by heat-resisting and non-conducting material.

—B. N.

Crucible furnace. F. E. Whitham, Sowerby Bridge, Yorks. Eng. Pat. 113,036, Apr. 17, 1917. (Appl. No. 5376 of 1917.)

A CRUCIBLE furnace has circumferential flues having inlets and outlets to each crucible tangential and diagonally opposite each other. Carbon monoxide generated from charcoal in a separate fire-box is supplied through branch pipes into each crucible.—W. R. S.

Furnace; Smelting—R. B. Llopart, Assignor to Mineral Refining and Chemical Corporation, St. Louis, Mo. U.S. Pat. 1,253,064, Jan. 8, 1918. Date of appl., Jan. 26, 1917.

A DOWN-DRAUGHT smelting-furnace has connected horizontal tiers of vertically spaced heating-flues, vertical flues to connect opposite alternate ends of the horizontal flues, and discharge flues connecting the lowermost tier of flues with the chimney. Connected horizontal muffles are disposed in tiers alternately and transversely through the spaces between the flues. The muffles are spaced apart one above another and connected at alternate ends to form a continuous zig-zag passage from top to bottom. Combustion chambers are disposed vertically adjacent to and controlling the flues. An ore-port is provided at the top of the furnace for feeding ore into the uppermost muffles; vertical ore-ways connect alternate opposite ends of the muffles, the latter having stoke-doors through which the ore is worked downwards. A flue

admits reaction gases into the lowermost muffles, the gases passing upwards through the muffles in the opposite direction to that of the ore and heat; a vent port at the top of the furnace allows the escape of the reaction gases.—W. R. S.

Zinc vapours; Condensers for—Norsk Elektrisk Metalindustri Aktieselskap, Sarpsborg, Norway. Eng. Pat. 105,559, Apr. 5, 1917. (Appl. No. 4955 of 1917.) Under Int. Conv., Apr. 8, 1916.

THE zinc vapour and gases from the distilling chamber pass by a horizontal pipe into the condensing vessel, the top of which just fits over the pipe outlet. This outlet is formed as a short downward branch from the horizontal vapour conduit and is provided with a vertical transverse partition, so that an outlet for the gases from the condenser into the extension of the vapour conduit is formed. The condenser is oscillated angularly about the pipe outlet so that the zinc which condenses as a powder is absorbed into the body of molten zinc at the bottom, the coating of oxide on the particles being detached by the movement.

—W. F. F.

Slag; Method for utilising the waste heat of—wherein the slag is granulated by means of air. C. Semmler, Wiesbaden, Germany. Eng. Pat. 112,792, Jan. 6, 1917. (Appl. No. 285 of 1917.)

MOLTEN slag is fed into the middle zone of a vertical tower, is granulated by a jet of compressed air, and passes downward over a series of oppositely inclined plates to a moving horizontal band or grid at the bottom. Air is circulated by a fan upward through the shaft to cool the slag and heat the air, and the hot air passes through the tubes of a boiler in the upper end of the shaft. The cooled air passes downward through a parallel shaft, through and over the granulated slag on the grid at the bottom of the two shafts, and the cycle is then repeated. The air used for granulating the slag is preheated by passing it through a coil in the downward shaft for the hot air, serving at the same time further to cool the latter. The circulating air is thus added to the air from the jet and both pass through the boiler tubes. In a modification, the air heated by the molten slag is used for the heating of Cowper stoves or to preheat the combustion air therefor.—W. F. F.

Gold and silver; Obtainment of—from their ores. A. A. Lockwood, London. Eng. Pat. 112,876, Apr. 18, 1917. (Appl. No. 5453 of 1917.)

THE pulped ore is agitated in a cyaniding vessel and then led to one end of a long shallow electrolysis vessel containing a series of parallel, vertical, longitudinal electrode plates. The pulp is kept in suspension by a jet of air and is led from the other end of the electrolysis vessel back to the cyaniding vessel. It is withdrawn from the cyaniding vessel through an open-ended vertical compartment provided with internal baffles to retain coarse particles of ore. The cathodes are preferably steel plates coated with carbon, and the anodes iron plates containing 30–40% Si ("tantiron").—W. F. F.

Electrode used in the electrolytic process of refining metals. F. L. Antisell, Perth Amboy, N.J. U.S. Pat. 1,250,757, Dec. 18, 1917. Date of appl., Feb. 8, 1913.

A ROD or bar, for suspending an electrode in an electrolyte, is provided on the under side with V-shaped projections, facing inwards and converging at their lower ends. The bar is also provided with a notch or recess at one end on its under side.—B. N.

Nickel from copper; Process of electrolytically separating — G. A. Guess, Oakville, Ontario, Canada. U.S. Pat. 1,251,511, Jan. 1, 1918. Date of appl., Aug. 14, 1917.

NICKEL sulphate solution is electrolysed using a copper-nickel anode, and a substantially insoluble reagent, such as calcium carbonate, which forms with copper an insoluble carbonate, and a sulphate, the presence of which is not detrimental in the electrolyte, is maintained in contact with the anode. The cathode is screened from contact with the carbonate.—B. N.

Electroplating apparatus. L. Potthoff, Flushing, N.Y. U.S. Pat. 1,251,568, Jan. 1, 1918. Date of appl., Dec. 14, 1916.

A TUMBLING barrel for the articles to be plated is supported in an electrolyte in a tank, the barrel being made in separable halves clamped together and holding between them a stationary cathode rod with cathode arms. The opposite heads of the barrel are provided with cathode plates having peripheral flanges and central bushings, the cathode rod being supported in the bushings but not free to rotate. Several peripheral cathode tracks of conducting material, continuous within the periphery of the barrel when assembled, support the articles to be plated, and rotate with the barrel to vary the points of contact between the articles and the tracks, the current being conducted from the tracks by the cathode rod. A movable chain engages with pins on the barrel to rotate the latter, and the barrel can be moved longitudinally to disengage the pins from the chain.—B. N.

Electroplating apparatus. L. Potthoff, Montclair, N.J., and G. W. Schweinsberg, Brooklyn, N.Y. U.S. Pat. 1,251,569, Jan. 1, 1918. Date of appl., May 12, 1917.

THE tank containing the electrolyte is provided with an endless conveyor for moving the articles through the electrolyte, and comprising links having vertical and horizontal bearing surfaces, which slide on a single rail track, supporting the conveyor. A guide strip engages the links and retains them in place on the track, and hooks, rigid with the conveyor, support the articles to be plated, so that the centres of gravity of the articles are in a vertical line below the track. A series of anodes are arranged in the tank parallel to the line of movement of the articles, and the electrolyte is agitated by a longitudinal pivoted bar near the bottom of the track substantially parallel to the anodes. Means are provided for vertically oscillating the bar backwards and forwards beneath the anode surfaces to cause movement of the electrolyte between the articles and the anodes, and across the line of feed of the articles, so as to renew the electrolyte and penetrate the recesses of the articles.—B. N.

[Tungsten] wires; Method of lubricating refractory — during drawing. K. Farkas, Assignor to A. B. Lisle, Providence, R.I. U.S. Pat. 1,253,362, Jan. 15, 1918. Date of appl., May 6, 1916.

THE process consists in applying an aqueous paste of magnesium oxide to the surface of the wire, heating it, and passing it through a heated diamond die.—W. R. S.

Ore concentration; Process of and apparatus for — O. D. Welsch, Kimberly, Nev. U.S. Pat. 1,253,653, Jan. 15, 1918. Date of appl., May 26, 1917.

THE method consists in agitating ore pulp within a confined space with compressed air, and then causing air under less pressure to pass downwards through and with the agitated pulp into the main body of pulp to form air bubbles in it and a froth

upon its surface. The process is carried out in a spitzkasten having froth and gangue discharges: a compressed air pipe extends into the spitzkasten below the level of the pulp or nearly to its lower end. The pipe discharges into an air lift chamber open at its upper and lower ends, the lower end extending below the lower end of the air pipe; its upper end has a deflector extending outwards and downwards. The air lift chamber is surrounded by an air chamber closed at its upper end, and extending into the space around and below the level of the upper end of the air lift chamber. A valve controls the pressure in the air chamber.—W. R. S.

Metals; Process of making — in electric furnaces. E. Humbert, Welland, Ontario, Canada. U.S. Pat. 1,252,443, Jan. 8, 1918. Date of appl., Apr. 26, 1917.

A CHARGE, partly at least in the solid condition, and containing an excess of carbon, is introduced into the furnace, and an arc is struck between an electrode and the solid portion, whilst a current of air is passed into the solid portion only, to oxidise the excess of carbon before the charge is melted. The operation is continued until the solid portion is melted and the molten charge refined to the desired extent.—B. N.

Furnace; Electric ore — J. A. Ward, Assignor to E. S. Campbell, W. A. Ridgeway, and H. Sorensen, Spokane, Wash. U.S. Pat. 1,252,635, Jan. 8, 1918. Date of appl., Apr. 12, 1917.

A FURNACE of the shaft type is surrounded by an electric heating coil, and a series of conducting pencils pass through the furnace wall so as to be in contact with the ore within it. An annular conducting band surrounds the crucible of the furnace and is in electrical contact with the furnace contents. A switch is provided for opening a circuit through the coil of wire, and for closing a circuit from the annular conducting band through the ore contents to the conducting pencils, the closing being effected slightly before the opening of the wire coil circuit. The current flowing through the heating coil is controlled by introducing in series into the circuit a number of adjustable arc-forming contacts or electrodes exterior to the heater. Means are provided for automatically adjusting the contacts to effect a regulation of the temperature in the coil of wire, and for utilising the heat generated by the arc or arcs formed between the contacts in aiding the process of ore reduction.—B. N.

Electro-deposition of metals. A. G. Betts, Asheville, N.C. U.S. Pat. 1,252,651, Jan. 8, 1918. Date of appl., May 15, 1916.

AN apparatus for the electro-deposition of metals comprises a lead-lined receptacle containing an anode and cathode spaced from the receptacle, with positive and negative terminals connected to the electrodes, and an independent connection, offering a relatively high resistance to the flow of the current, between the lead lining and the negative terminal. A salt of a metal of greater solubility in the acid of the salt than lead, is electrolysed, whilst maintaining at the lead surface a negative potential high enough substantially to prevent the formation of a lead salt.—B. N.

Fume condenser. T. B. Stewart, Portola, Cal. U.S. Pat. 1,252,731, Jan. 8, 1918. Date of appl., Jan. 6, 1917.

A HORIZONTAL tank is provided with a chimney at one end and with upper and lower horizontal partitions. At the end of the upper partition opposite the chimney, a cap extends upwards and the gaseous products from the smelter are introduced into the cap near the top. Inclined baffle-

plates project from the inner wall of the chimney and have water-spraying devices at their inner ends. The water is circulated through the tank and around the partitions, and the fumes pass from the cap through the water between the partitions to the chimney.—T. H. B.

Alloys; Process of making — H. L. Doherty. New York. U.S. Pat. 1,252,887, Jan. 8, 1918. Date of appl., Aug. 27, 1917.

ALLOYS of metals of widely different melting points are made by heating the metals, at a temperature sufficient to melt the less fusible metal, in a casing, under sufficient pressure to prevent volatilisation of the more volatile metal. The alloy is cast under pressure.—T. H. B.

Ore concentration. R. B. Martin, New York. Eng. Pats. 103,990 and 103,991, Jan. 27, 1917. (Appl. Nos. 1393 and 1394 of 1917.) Under Int. Conv., Jan. 28, 1916.

Metals; Electrolytic recovery of — from their solutions. U. C. Tainton, Johannesburg, Transvaal. U.S. Pat. 1,251,302, Dec. 25, 1917. Date of appl., July 6, 1915.

SEE Eng. Pat. 11,336 of 1915; this J., 1916, 969.

Electric furnace. U.S. Pat. 1,252,633. See XI.

XI.—ELECTRO-CHEMISTRY.

Furnace; A high temperature electric resistance — W. Rosenhain and E. A. Coad-Pryor. Faraday Soc. [Advance proof.] 7 pages.

THE graphite or carbon resistor is in the form of a tube, made up of superposed rings, with conical top and bottom surfaces so that they fit accurately one upon the other; the rings are turned from a solid tube or rod of graphite. The thickness of the rings may be varied so as to increase or diminish the number of rings for a given height of tube, and thus vary the number of zones of contact for varying the resistance and the temperature. The ends of the tube are connected to metallic water-cooled electrodes, and the tube is surrounded by finely-divided carbon, or vegetable black, and magnesia blocks enclosed in a metal case. In a furnace of this type with rings 2½ in. internal diameter, about 100 heats at temperatures ranging from 1500° to 2400° C. were obtained in a period of six weeks, and the only repairs then necessary consisted in replacing the top six rings by new ones. In a furnace of 2¾ in. internal diameter a temperature of 1500° C. can be attained in 30 mins. with a consumption of 8 kilovolt-amperes, and 1700° C. with a consumption of 10 kilovolt-amperes (400 amperes, alternating current, at 25 volts). In a furnace of 3½ in. diam., pure iron can be melted with a power consumption of 10 kilovolt-amperes taking a current of 550 amperes. In a still larger furnace of 7 in. internal diameter a temperature of 1650° C. was attained with a power consumption of 23 kilovolt-amperes (2000 amperes); the lower efficiency is due to the smaller ratio of length to diameter of furnace. —B. N.

PATENTS.

Electrolytic apparatus. L. W. Chubb, Edgewood Park, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,250,141, Dec. 18, 1917. Date of appl., Jan. 10, 1917.

AN electrolytic cell contains a series of superposed horizontal plates of film-forming metal, spaced apart, alternate plates being connected with each other so as to form two distinct sets. The plates

are provided with openings of two different sizes, the larger openings in each plate being so disposed as to register with the smaller openings in the adjacent plates. Rods extend through the registering openings in the plates, and spacing members of film-forming metal surround the rods between the plates, and, being of less diameter than the larger openings in the plates, they extend through these openings and thus allow the plates comprising each alternate set to be rigidly clamped together in spaced relationship.—B. N.

Electrolytic apparatus. J. Coulson, Wilkesburg, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,250,146, Dec. 18, 1917. Date of appl., Jan. 6, 1917.

TWO sets of vertical plates of film-forming metal are employed, and each set is supported and rigidly clamped by horizontal spacing members, the members clamping one set of plates passing through openings in the second set. The spacing members are provided with screw-threaded and tapped openings, whereby several are connected together to form a substantially continuous rod. Means are provided for removing the plates from the container, and for preventing movements of the spacing member rods towards the ends or sides.—B. N.

Secondary storage battery and method of making the same. C. S. Palmer, Newtonville, Mass. U.S. Pat. 1,251,412, Dec. 25, 1917. Date of appl., July 23, 1915.

THE electrode is composed of a grid comprising lead supporting plates, approximately 0.12 in. in thickness, with laminations forming lead shelves approximately 0.02 in. in thickness, and spaced apart approximately 0.04 in. Active material containing the "PbO" radical fills the spaces between the shelves. The electrode is immersed in an electrolyte consisting essentially of a concentrated solution of sodium bisulphate over 1.1 sp.gr., containing approximately 4 to 8% of additional sulphuric acid. The material is subjected alternately to the charging and discharging action of an electric current.—B. N.

Furnace; Electric — C. H. Vom Bauer, Douglaston, N.Y. U.S. Pat. 1,252,633, Jan. 8, 1918. Date of appl., Aug. 6, 1917.

THE furnace is provided with a solid bottom and an oval-shaped refractory side wall, of such a form that the end portions in plan are parts of arcs of circles of equal radii but different centres, the middle portion forming the arcs of a circle of a radius $\sqrt{2}$ times the radius of each end arc. The centres of all the arcs are in line, and three electrodes, located approximately at the centres of the arcs, are connected to a two-phase three-wire current supply. The electrodes are thus spaced, so that, at the slag line, the heat gradient is the same for each electrode at the point of the side wall which is nearest to such electrode.—B. N.

Electric furnace control apparatus. J. A. Seede, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,253,732, Jan. 15, 1918. Date of appl., June 21, 1917.

THE control apparatus comprises arc-supporting electrodes, connected to conductors supplying energy, and also connected operatively to motors. Means are provided for controlling the motor connected to one electrode, so as to regulate the length of the arc in response to variations in current in the supply circuit, and to move the electrode in a direction whereby a desired current value is maintained. The second motor responds to voltage changes, and moves the electrode in a direction whereby a desired voltage drop is main-

tained, means being also provided for braking the motors when the desired regulation has been attained.—B. N.

XII.—FATS; OILS; WAXES.

Sulphonation of fixed oils. L. G. Radcliffe and S. Medofski. J. Soc. Dyers and Col., 1918, 34, 22—35.

The authors give a summary of the literature of the subject and a bibliography, followed by the results of their own experiments. Various oils were sulphonated, the fatty acids liberated from the sulphonation products as described by Radcliffe and Palmer (this J., 1915, 613), and the characters of these fatty acids compared with those of the fatty acids from the original oils. Sulphonation was effected by adding concentrated sulphuric acid (35, 50, or 75 grms.), drop by drop, to 100 grms. of the oil contained in a jar cooled by ice, the mixture being agitated continually and the temperature not allowed to rise above 15° C. No sulphur dioxide was evolved. After all the acid had been added, the mixture was stirred for a further 2 hours, left at rest for some hours, washed with a saturated solution of sodium sulphate, and heated in a water-oven till clear. The heating in a water-oven caused charring of the products from linseed and rape oils and was omitted in these cases. In the case of sesame, cottonseed, and olive oils, the chief effects of sulphonation on the fatty acids were a rise of the solidifying point, and diminution of the iodine value and neutralisation value; the acetyl value was considerably increased, indicating the formation of hydroxy-compounds, the increase being greater the higher the proportion of olein or oleic acid present. With rape and whale oils similar results were obtained, except that there was no marked increase of the acetyl value, indicating that with these oils there was no notable formation of hydroxy compounds but production of lactones (or anhydrides) or polymerides. The fatty acids from sulphonated linseed oil agree fairly closely in character with those from the original oil, i.e., there is no considerable formation of stable new compounds, either lactones or hydroxy-compounds. With castor oil, also, no new hydroxy compounds are formed, but the lower acetyl value and iodine value of the fatty acids from the sulphonated oil and the difference between the saponification value and neutralisation value of these acids indicate the formation of polyricinoleic acids (see Juillard, this J., 1892, 355; 1893, 528; 1891, 820). The combining powers of various oils and fatty acids with sulphuric acid or their "sulphonation numbers," were determined by treating 5 grms. of the oil or fatty acid with 25—35% of concentrated sulphuric acid, added drop by drop, at 0°—5° C., allowing to stand for 2 hours, dissolving the product in neutral alcohol, and titrating with alkali. The difference between the amount of alkali required and that which would have been required if no combination had taken place, is a measure of the combining power of the oil with sulphuric acid. The following

values (mgrms. KOH per gm. of oil or fatty acid) have been obtained: oleic acid, 67.75; olive oil, 63.42; rape oil, 53.76; sesame oil, 32.76; whale oil, 26.40; linseed oil, 21.4; palmitic acid, 8.21; stearic acid, 7.63. With the exception of rape oil the order corresponds with that in which the acetyl value of the fatty acids has increased after sulphonation. The figures show that the ease with which oils react with sulphuric acid depends not upon the "degree of unsaturation," but upon the percentage of olein or oleic acid present. Saturated fatty acids are not affected by sulphuric acid. In the case of highly unsaturated oils, such as linseed oil, the action of sulphuric acid is probably either to form unstable addition products (sulpho compounds) or to cause polymerisation, the polymers being easily decomposed. With all oils sulphuric acid acts to some extent as a hydrolysing agent, the liberated glycerol remaining in the mixture, either in the free state or as sulpho-glycerol compounds. In the case of oils containing a large percentage of olein, as for example, olive oil, the action of sulphuric acid is confined (beyond the hydrolysis of the triglycerides) to the olein, which is converted into saturated compounds, viz., *θ*-tri-olein-hydrogen-sulphate,

$C_3H_5[CH_3(CH_2)_7 \cdot CH_2 \cdot CH(ISO)_1 \cdot (CH_2)_7 \cdot COO]_3$, and *i*-tri-olein-hydrogen sulphate,

$C_3H_5[CH_3(CH_2)_7 \cdot CH(ISO)_1 \cdot CH_2(CH_2)_7 \cdot COO]_3$. These compounds are unstable and are easily saponified, yielding sulphuric acid and hydroxy-acids. The *θ*-hydrogen-sulphate yields *θ*-hydroxystearic acid, $CH_3(CH_2)_7 \cdot CH(OH) \cdot (CH_2)_7 \cdot COOH$, which undergoes immediate transformation into stearolactone, and the *i*-hydrogen-sulphate yields *i*-hydroxystearic acid,

$CH_3(CH_2)_7 \cdot CH(OH) \cdot (CH_2)_7 \cdot COOH$, which is stable. According to this view Turkey-red oil derived from olive oil, when neutralised with sodium carbonate, would contain the sodium salts of *θ*- and *i*-hydroxystearic acids, unchanged saturated and unsaturated glycerides, and the sodium salts of oleic and palmitic acids, together with the sulpho-compounds formed. According to Geitel and Juillard (this J., 1888, 218, and *loc. cit.*) the chief saturated product is a neutral sulpho-compound:

but the corresponding *i*-compound may also be formed. These products are more unstable even than the hydrogen-sulphates mentioned above and like them yield the corresponding *θ*- and *i*-hydroxystearic acids.

Some preliminary experiments on the sulphonation of Chinese wood oil (tung oil), the preparation of pure linolenic acid, and the separation of the sulpho-compounds produced on sulphonating olive oil are described.

Fats and oils; Tentative standard methods for sampling and analysis of commercial—other than those of the coconut, butter, and linseed groups. J. Amer. Leather Chem. Assoc., 1918, 13, 14—28.

The methods described have been worked out by a committee of the American Chemical Society, and are put forward as tentative standards for industrial chemists pending their adoption by the Society. Careful directions are given for sampling under all circumstances. No sample should be accepted for analysis which does not amount to 3 lb. at least. Moisture and volatile matter are determined by drying to constant weight in a vacuum oven specially designed to give uniform temperature throughout. The pressure in the oven must be less than 100 mm. of mercury, and the temperature 15°—20° C. above the boiling point of water at that temperature, i.e., if the pressure in the oven is 70 mm., the temperature

must lie between 60° and 65° C. Distillation methods were carefully considered before the above was adopted. A more rapid method is suggested for routine work. Insoluble impurities are determined by treating the dried material with kerosene, using petroleum ether for a final washing of the residue. By this means all metallic soaps are dissolved and are determined as soluble mineral matter on burning off the kerosene from the filtrate. For the titer test, the fat is saponified by a 25% solution of caustic potash in glycerin. In the determination of unsaponifiable matter, petroleum ether has been adopted for extracting, after careful consideration of the suitability of ethyl ether. The extraction is carried out in a stoppered measuring cylinder, and the ether layer siphoned off. A blank determination is made with pure dry stearin. Methods involving the evaporation of the fat with the alkaline solution and subsequent extraction of the dry residue were found unsatisfactory.—F. C. T.

Use of chaulmoogra oil as a specific for leprosy.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Resins; Exudation —. IX. M. Bamberger and H. von Klimburg. Monatsh. Chem., 1917, 38, 457.

THE resin obtained from the stone pine (*Pinus cembra*) possesses an odour recalling vanillin, becomes reddened on exposure to light, and has m. pt. about 70° C., acid value 127, and iodine value 112, but the figure for the last is as low as 78.4 if the resin is previously purified by dissolving in alcohol and then pouring into water acidified with hydrochloric acid; the methoxyl content is lower than in other natural resins, amounting only to 13 parts per 1000. Boiling water extracts from the resin caffeic acid and also small quantities of ferulic acid and vanillin, whilst the residual molten resin on fusion with potassium hydroxide yields *p*-hydroxybenzoic acid, catechol, protocatechuic acid, acetic acid, and a trace of butyric acid. As with the resins investigated earlier, stone pine resin, after extraction with water, can be separated into an α -resin soluble and a β -resin insoluble in ether, the α -resin, which has a much lower methoxyl content than the β -resin, predominating. Attempts to produce a resinol analogous to pinoresinol or lariciresinol (Bamberger and Landsiedl, this J., 1895, 45) were unsuccessful. Lariciresinol when heated with zinc dust in a stream of hydrogen yields a distillate containing toluene, xylene, naphthalene, methyl-naphthalene, a trace of guaiacol, and probably

also cumene. Lariciresinol also gives a resinous ozonide but the only decomposition product identified after shaking with water was hydrogen peroxide. Pinoresinol is already known to contain two hydroxyl groups; by heating with alcohol and a little sulphuric acid it can be converted into an amorphous anhydro-compound, $C_{15}H_{14}O_3$, which resists the action of methyl sulphate in alkaline solution but on treatment with acetyl chloride yields diacetylpinoresinol.—D. F. T.

PATENTS.

Phenolic condensation product; Method of producing a —. J. P. A. McCoy, Wilkinsburg, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,253,261, Jan. 15, 1918. Date of appl., Mar. 20, 1913. Renewed June 28, 1916.

A SHAPED condensation product is formed by reacting upon a phenolic substance with a substance containing an active replaceable methylene group, e.g., formaldehyde, in the presence of carbon dioxide, arresting the reaction when the product has become infusible and insoluble but is yet capable of softening under the influence of heat, shaping the product and applying heat to it.

—A. DE W.

Phenolic condensation product. J. P. A. McCoy, Wilkinsburg, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,253,262, Jan. 15, 1918. Date of appl., Dec. 4, 1915.

A SHAPED resinous condensation product is obtained by reacting upon a phenolic substance with a material containing an active replaceable methylene group, i.e., hexamethylenetetramine, dissolving the resulting product in a solvent containing hexamethylenetetramine, passing carbon dioxide through the solution, separating the resulting resinous material from the solvent, and finally moulding it with heat.—A. DE W.

Phenolic condensation product; Process of preparing a —. J. P. A. McCoy, Wilkinsburg, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,253,404, Jan. 15, 1918. Date of appl., Feb. 5, 1914. Renewed Nov. 30, 1917.

RESINOUS products are prepared by treating a phenolic substance with a condensing agent mixed with a reactive reduction product of such condensing agent, e.g., a mixture of carbon dioxide and formaldehyde from partially reduced carbon dioxide.—A. DE W.

Turpentine oils; Process of refining and deodorising raw —. H. Dedichen and O. Halse, Assignors to Union Co., Christiania. U.S. Pat. 1,253,793, Jan. 15, 1918. Date of appl., Jan. 31, 1917.

RAW turpentine oil is first subjected to chemically active rays in the presence of a gaseous oxidising agent, and is then treated with iron chloride, whereby a refined turpentine oil is obtained consisting of "a pure mixture of α and β pinene and comprising dextro-rotary β pinene."—A. DE W.

Paint compositions. W. E. Wright, Cleveland, Ohio, U.S.A. Eng. Pat. 109,255, July 26, 1917. (Appl. No. 10,775 of 1917.) Under Int. Conv., Aug. 26, 1916.

SEE U.S. Pat. 1,226,934 of 1917; this J., 1917, 894.

Phenols and formaldehyde; Process for obtaining hard products of condensation of —. K. Tarassoff, Moscow, and P. Shestakoff, Petrograd, Russia. U.S. Pat. 1,252,507, Jan. 8, 1918. Date of appl., Feb. 8, 1916.

SEE Eng. Pat. 104,887 of 1916; this J., 1917, 558.

XIV.—INDIA-RUBBER ; GUTTA-PERCHA.

Reclaimed rubbers ; Method of valuation of —. J. B. Périgrin. Caout. et Gutta-percha, 1918, 15, 9436.

THE approximate rubber content of samples of reclaimed rubber was ascertained by difference after determining the ash, sulphur, and loss by successive extractions with acetone, alcoholic sodium hydroxide, and pyridine respectively, and the cost of the actual rubber present was calculated from the selling price of the material. In a number of samples examined, this cost worked out at figures varying from about 1s. 6d. to about 3s. 4d. per lb.—E. W. L.

XV.—LEATHER ; BONE ; HORN ; GLUE.

[Tanning] extract analysis ; Comparative —. J. M. Seltzer. J. Amer. Leather Chem. Assoc., 1918, 13, 9—11.

TANNING extract was sampled by the manufacturer and the tanner, and each sample was analysed by the tannery chemist and the manufacturer's chemist, 100 such analyses are tabulated for comparison. The averages for the whole series show a greatest difference of only 0.07% tannin.—F. C. T.

Leather ; Determination of ash in —. O. Riethof and C. T. Gayley. J. Amer. Leather Chem. Assoc., 1918, 13, 7—9.

THE authors suggest that the insoluble ash should be determined by incinerating the dried, extracted leather, and the soluble ash preferably by evaporating the aqueous leather extract and igniting the residue. The sum of these determinations gives the total ash. By adopting such a uniform procedure the present variations and errors can be largely avoided.—F. C. T.

XVI.—SOILS ; FERTILISERS.

Soil reaction ; Studies in — as indicated by the hydrogen electrode. J. K. Plummer. J. Agric. Res., 1918, 12, 19—31.

MEASUREMENTS of the reactions of soils in suspension in water, and of the film water from soils, obtained by the oil pressure method in a Morgan apparatus (this J., 1917, 972), have been made by means of a hydrogen electrode. It was found that the film water from a soil has the same reaction as the free water, differing only in intensity. Ammonium sulphate, applied to soils, materially increases the hydrogen ion concentration, and potassium sulphate does so to a less extent, whilst acid phosphates do not appear to affect the hydrogen ion concentration of field soils. Sodium nitrate slightly reduces the acidity of soils, whilst lime materially increases the hydroxyl ion concentration. The acidity developed from ammonium sulphate is more intense in the film water than in the free water of soils.—W. G.

Manures ; Decomposition of green and stable — in soil. R. S. Potter and R. S. Snyder. J. Agric. Res., 1917, 11, 677—698.

SOIL organic matter decomposes more rapidly in a soil to which calcium carbonate has been applied, than in untreated soil. Similarly the decomposition of the total organic matter of a soil, after the application of stable manure or green manure in the form of oats or clover, is more rapid under the influence of calcium carbonate than without it, stable manure seems to increase the rate of decom-

position of green manure to a slight extent. Both of these manures tend to conserve the lime in the soil.—W. G.

Fertilisers ; Action of various —, especially manganese sulphate, on the growth of oats. L. Hiltner and G. Korff. Biedermann's Zentr., 1918, 47, 15—19.

OATS were grown in various types of soils in 8 litre pots and manured with 25 grms. of manganese sulphate, copper sulphate, or iron sulphate, or with 50 grms. of powdered sulphur. Each pot of soil also received 25 grms. of guano. In every case, an increase in the yield of oats was noted in the manured as compared with control unmanured soils, especially in those soils treated with manganese sulphate. The effect of the manganese was most marked when applied to soils containing much humus : in peaty soils, the yield of oat-grains was 70 times as great in the presence as in the absence of manganese. (See also J. Chem. Soc., Mar., 1918.)—H. W. B.

"Zeolitic" silicic acids ; New method for the estimation of — in soils. G. Guedroit. Rev. Exp. Agron. Petrograd, 1916, 17, 400—407. Bull. Agric. Intell., 1917, 8, 1190—1191.

FOR the estimation of the "zeolitic" silicic acids liberated during the treatment of soils with hot, concentrated hydrochloric acid, the following procedure is recommended. Five grams of soil is subjected to the acid treatment and then heated in a platinum dish at a temperature not exceeding 62.5°C. until the organic matter is all destroyed. The residue is heated on a water-bath for half an hour with 100 c.c. of 5% potassium hydroxide solution and filtered, the insoluble portion being washed ten times with a 1% solution of potassium hydroxide. The filtrate is acidified with hydrochloric acid and evaporated to dryness, the residue being heated at 125°—150°C. for 1—1½ hours. The silicic acid may then be separated and estimated in the usual manner.—W. G.

Nitrogen-fixing bacteria ; Physiology and biology of —. V. L. Omeliansky. Arch. des Sciences Biol. de Petrograd, 1916, 19, 209—227. Bull. Agric. Intell., 1917, 8, 1190.

A CRITICAL discussion of important recent work on *Clostridium* (see this J., 1917, 40) and an account of new experiments on the biology and physiology of that organism. Growth is more abundant and the fermentation of sugar more energetic at about 30°C. but nitrogen-fixation is less than at the ordinary temperature. *Clostridium* may be heated to 75°C. without destruction, and thus other non-sporing species may be eliminated by prolonged pasteurisation at that temperature. Spores of *Clostridium* may be preserved in the dry state in air for 20 years without losing their power of nitrogen-fixation. With cultures in the presence of carbohydrates, the fermentation of ten carbohydrates (dextrose, levulose, sucrose, galactose, maltose, raffinose, dextrin, inulin, glycerol, mannitol) was observed, the most vigorous growth occurring with dextrose, raffinose, inulin, and mannitol. Sugar concentration has a great influence on the nitrogen-fixation by *Clostridium* ; the greater the concentration the less the nitrogen-fixation per gram of sugar. The manner in which the nitrogenous food is supplied also has an effect on the fixation, too large an increase in nitrogen-content of the medium causing a decrease of fixation and finally stopping it. With a *Clostridium* from Volhynie, however, nitrogen-fixation still took place when the ratio of nitrogen to sugar in the medium was 16 : 1000. The author agrees with Winogradsky that *Clostridium* is a typical butyric ferment.—W. G.

Phosphoric acid; Determination of — particularly in superphosphate. G. Vortmann. Z. anal. Chem., 1917, 56, 465—487.

In the precipitation of phosphoric acid as ammonium magnesium phosphate, the presence of ammonium sulphide and oxalate does not interfere with the results obtained; ammonium molybdate is also without influence. Large quantities of aluminium salts interfere with the precipitation unless an excess of "magnesia mixture" is used. If the phosphoric acid is first separated by precipitation with molybdic acid, this precipitation may be made in either nitric, hydrochloric, or sulphuric acid solution. The addition of pyridine to molybdic acid solution increases the sensitiveness of the latter; 0.01 mgrm. P_2O_5 in 10 c.c. of solution may be detected, whilst the limit for the usual molybdic acid reagent is about 0.1 mgrm. P_2O_5 in 10 c.c. The mercury oxide method for the determination of phosphoric acid in superphosphate is accurate; in this method, the phosphoric acid is precipitated, by means of yellow mercury oxide, as a basic mercury phosphate, the latter is decomposed by sodium sulphide, and the phosphoric acid then determined by the magnesia method. Precipitation of the phosphoric acid as calcium triphosphate is unreliable. (See also J. Chem. Soc., Mar., 1918.)—W. P. S.

Borax as destructive of vegetation. W. H. Roberts, A. Smetham, and J. A. Voelcker. Analyst, 1918, 43, 58—59.

In a few cases, in which it was alleged that damage had been done to a sewage farm through the turning on to it of waste-liquor from borax works, the evidence of the authors for the plaintiffs showed that the presence of borax in the soil was the one and only cause of the destruction of the crops. Samples of the damaged soil, dried at 100° C., contained 0.01, 0.032, 0.036, and 0.163% of borax, whilst the soil from other parts of the farm on which an altogether different effluent flowed was free from borax. Experiments carried out by J. A. Voelcker at the Woburn Experimental Station (J. Roy. Agric. Soc. Eng., 1915, 76) showed that the presence of 0.013% of borax in a soil was destructive to wheat and barley, and other experiments indicated the possibility of borates accumulating in the soil.—W. P. S.

XVII.—SUGARS; STARCHES; GUMS.

Moulds; A case of raw sugar deterioration caused by —. W. J. T. Amons. Archief Suikerind. Ned.-Indië, 1917, 25, 1225—1231.

FROM a sample of deteriorated raw sugar taken from a store, various moulds were isolated, amongst which were *Aspergillus niger*, *A. fumigatus*, *A. flavus*, *A. clavatus*, *Penicillium glaucum*, *P. purpurogenum* (Stoll), a few yeasts and bacteria being also present. It was found possible to induce the deterioration of raw sugar under suitable hygroscopic conditions by means of *Penicillium glaucum* alone in the absence of bacteria. The author believes that probably no one micro-organism is solely responsible for sugar deterioration, and that at one time moulds, at another bacteria, may be the cause, depending upon the conditions prevailing at the time of infection.—J. P. O.

[Sugar] factories using the defecation process; Filtration of muddy juice in Java —. A. Schweitzer and G. Loos. Archief Suikerind. Ned.-Indië, 1917, 25, 1561—1563.

CERTAIN factories using the ordinary defecation process had Kelly presses installed, and it was found, contrary to what had been experienced in

defecation-sulphitation houses, that the capacity of the filters was not as great as expected, the difficulty being principally in sweetening off, but also in dropping the mud from the frames and in cleaning the cloths. Efforts were made to improve matters by the addition of materials such as fine carbon to the mud, but unavailing. Suspecting that the absence of crystalline calcium sulphite might account for the difficult filtration, liming and sulphitation of the muddy juices was carried out, using 10—14 litres of 15 B. lime cream to 1000 litres of juice and sulphiting to neutrality to phenolphthalein. This treatment was entirely satisfactory, results analogous to those obtained in defecation-sulphitation factories being thus obtained.—J. P. O.

Sugar refining; Use of vegetable decolorising carbon ("Norit"), as compared with animal charcoal (boneblack) in —. J. Sauer. Intern. Sugar J., 1918, 20, 24—29.

REPLYING to criticisms upon the use in sugar refining of decolorising carbon, particularly the vegetable material known as "Norit," it is claimed that volume for volume 3 parts is capable of exerting the same decolorising effect as 100 parts of animal charcoal. Not only colouring matter, but gums, pectins, and other non-sugar bodies, as well as mineral matter, are adsorbed from solution by the carbon, and can be found in it after use. In the factory decolorisation is carried out after clarification with lime and filtration, and preferably in a solution that is distinctly acid, using sulphurous or phosphoric acid, while boiling may be carried on for 15 minutes or even longer without inversion occurring. It is claimed that in the revivification of decolorising carbon according to the "Norit" patents (this J., 1913, 85; 1914, 853), the adsorptive power decreases to a less extent after each re-burning than in the case of animal charcoal, so that it is more economical in use. Decolorising carbon is now being employed in cane and beet factories and refineries in different parts, and also in other establishments, those, for example, making jam, chocolate, biscuits, or lemonade, for which a white sugar is required.—J. P. O.

Cane sugar manufacture [in Hawaii]; Separation of non-fluid impurities from juices, syrups, and molasses in —. E. Kopke. Intern. Sugar J., 1918, 20, 29—32.

MILL juice carries with it as mechanical impurities principally small particles of bagasse and earth, and for their removal screens of perforated brass with mechanically operated slat scrapers are now exclusively used in Hawaii, though a revolving screen arranged above the intermediate bagasse conveyor is to be installed. Very fine particles of bagasse passing through the ordinary perforations are intercepted by wire cloth of 100—200 mesh. Lined and heated juices are allowed to subside in tanks of either intermittent or continuous type. Filters, the medium in which may be cloth, sand, bagasse, or "Excelsior," are also used, but less every year, notwithstanding the excellent results, as they are costly in respect of labour, quantity of medium, and loss of sugar. Scum and mud collected from the settling tanks of lined and heated juices is separated from any remaining juice in filter-presses, and besides those of the plate-and-frame type, the Kelly and Sweetland presses are now being used in Hawaii. Overhead supply tanks delivering under pressure remain the best arrangement for passing the scums and mud to the presses; a centrifugal pump is in most cases quite as satisfactory; but reciprocating pumps giving a pulsating delivery are objectionable, and should only be used in conjunction with a supply tank. Syrup and molasses

contain principally gummy substances and calcium salts as mechanical impurities, for the removal of which settling is out of the question, while filtration when the gums are high is also impossible. Very encouraging results have, however, been obtained during the past three campaigns with a clarifying centrifugal (this J., 1917, 398), which machine is capable of operating continuously. Analysis of some of the mud taken from this apparatus after clarifying a molasses gave the following percentage results: organic matter, 51.85; silica, 4.85; iron and alumina, 2.25; lime, 21.49; magnesia, 3.94; phosphoric acid, 4.17; sulphuric acid, 9.88; carbon dioxide, 0.62. Combining these constituents, the residue is shown to contain: calcium phosphate, 9; calcium sulphate, 7; and compounds of lime and organic acids, about 22 per cent. It would, therefore, resemble evaporator scale, except in the large proportion of organic matter.

—J. P. O.

Sucrose content; Some methods for the determination of the — of [cane] molasses. T. van der Länden. *Archief Suikerind. Ned.-Indië*, 1917, 25, 1240—1272.

A COMPARATIVE examination of the several methods that have been proposed to obviate the error in the double polarisation method due to the presence of optically-active impurities, the rotations of which are also affected by the acid used for hydrolysis, has led to the following conclusions. Uniformly concordant results were obtained with the processes of Tervoooren (*Archief Suikerind. Ned.-Indië*, 1904, 321) and Steuerwald (this J., 1913, 1025), in the latter of which hydrolysis is not carried on at 68°—70° C., but at the prevailing temperature: with Java molasses, however, the liquid obtained in both methods, after clarifying with basic lead acetate, was so dark as to make the direct reading hardly possible, even in a 100 mm. tube. On the other hand, Pellet's sulphurous acid method (*Bull. Assoc. Chim. Sucr.*, 8, 623; this J., 1897, 474) gave an excellent clarification, while the results were equal to or only slightly lower than those found by the methods of Tervoooren and Steuerwald. Stanek's method (this J., 1914, 705) proved unsatisfactory with Java molasses, difficulty being experienced in clarifying with bromine as prescribed, whilst the results were distinctly lower than those found by the methods of Tervoooren or Steuerwald. Saillard's method (this J., 1913, 836) was found too tedious for routine work, and was not applied, nor was the invertase method described by Ogilvie (this J., 1911, 62), owing to the difficulty of obtaining and preserving yeast in the tropics. Deerr's method (this J., 1915, 503), though theoretically exact and of value in special investigations, is too lengthy and involved for routine factory work. It gave the lowest results of all. Pellet and Lemeland's process of polarising after the destruction of the reducing sugars by alkali (*Bull. Assoc. Chim. Sucr.*, 1915, 33, 89), as well as its modification by Cross and Taggart, is not considered trustworthy, there being a considerable difference between the polarisations before and after acidifying with acetic acid, while the values it yields, though regular in themselves, are not in accord with those given by the double polarisation method of Steuerwald. In treating reducing sugars with alkali under the conditions of the method, the *lævo*-rotation is not totally removed, and a slight oxidation of sucrose occurs, especially when hydrogen peroxide is used. In general, the several methods examined are more complicated than the "cold inversion" process of Steuerwald now in use in Java, and none can be recommended in preference to it. A combination of Pellet's sul-

phurous acid method and Steuerwald's method, however, might advantageously be employed, as in this way the difficulty in obtaining light-tinted liquids experienced in working with certain molasses, particularly those from carbonatation factories, would be overcome.—J. P. O.

Molasses; Dry substance and sucrose determinations in cane —. L. G. L. Steuerwald. *Archief Suikerind. Ned.-Indië*, 1917, 25, 1117—1425.

SAMPLES of well-mixed and previously analysed molasses were sent from the experiment station to the sugar factories in Java with the request that the dry substance should be determined in them by the Josse method of drying on a coil of bibulous paper and the sucrose by the Tervoooren double polarisation process. As a whole the results returned for the dry substance content were very unsatisfactory, varying between wide limits, the conclusion being that the Josse method is unsuitable for factory routine work. On the other hand, the figures for the sucrose content concurred well with those found at the experiment station.

Formation of lactose from starch by the "loosened" ferments of sucrose serum. Röhmnn. *See* XVIII.

XVIII.—FERMENTATION INDUSTRIES.

[Yeast;] *Maltase-activity [of —] in relation to fermentation and storage. The maltase activity of different yeasts. Influence of oxygen on the maltase-activity of yeast in beer.* F. Schönfeld and H. Krumhaar. *Woch. Brau.*, 1917, 34, 60—62, 157—159, 165—166, 189—190.

I. YEAST maltase, like zymase, is an intracellular enzyme and can only be extracted after the yeast has been dried or the cells ruptured by mechanical means. It does not appear to escape from cells which die under normal conditions, *e.g.*, during the storage of beer. In the fermentation of all-malt worts the hexoses are eliminated at a relatively early stage (see this J., 1916, 1230), and as the destruction of maltose requires the presence of maltase as well as zymase, a deficiency of either of these enzymes may cause the later stages of fermentation to become sluggish. II. To compare the maltase-activity of different yeasts the authors introduced equal quantities (5 or 2%) into 5% or 2% maltose solutions with 8% of toluene, and maintained the liquids at 6°—7° C. The amounts of dextrose formed after successive intervals of 1 or 2 days were determined by conversion into glucosazone. The amount of toluene used completely suppressed the action of the zymase of the yeast, and the rate of formation of dextrose was therefore regarded as a measure of the maltase-activity of the yeasts. The results for a number of brewery yeasts indicated a general parallelism between maltase-activity and attenuating power, and the latter is considered to be dependent on the former. III. From further experiments it is concluded that the maltase-activity of yeast is stimulated by aeration, and may become permanently weakened by prolonged deprivation of air. Since the after-fermentation of all-malt beers proceeds mainly at the expense of the maltose remaining after the primary fermentation, it is largely controlled by the maltase-activity of the yeast present during storage, and will therefore be stimulated by the introduction of air into the beer, *e.g.*, by means of rousing or the use of chips, which contain a considerable amount of air in their pores.—J. H. L.

Feast ; Reproduction of —. T. Bokorny. Woch. Brau., 1917, 34, 269—271.

In the fermentation of sugar solutions the weight of yeast produced, expressed as a percentage of the weight of sugar decomposed, varies greatly according to the conditions ; different investigators have found values as low as 0.8% and as high as 14%. The author obtained a still higher result, 16%, in the fermentation of sucrose solution containing only urea as source of nitrogen (cp. this J., 1917, 1284), the liquid being exposed to the air in a very shallow layer, only 0.1 inch thick. An important factor which influences the relative amounts of sugar fermented and assimilated is the rate of fermentation. When the amount of yeast present is large, so that fermentation proceeds rapidly and is soon complete, little or even none of the sugar may be assimilated, i.e., no fresh yeast may be formed. If the sugar is added to a yeast suspension in small quantities at intervals, a larger proportion of it will be assimilated than if it is added all at once at the outset. The difficulties which have been experienced in the production of beers of very low gravity, owing to insufficient yeast crops and degeneration, may possibly be avoided by employing a smaller amount of pitching yeast, so that in consequence of slower fermentation a larger proportion of the sugar may be assimilated by the yeast.—J. H. L.

Worts ; Proximate constituents of sweet and hopped — at successive stages of the mashing process. A. R. Ling. J. Inst. Brew., 1918, 24, 15—21.

It has been held by practical brewers that if the extraction of the contents of the mash tun is carried to completion, the last runnings are liable to contain undesirable substances which may cause trouble at a later stage, and chemists have attributed this to the extraction of excessive amounts of nitrogenous matters. Some analytical data are now presented which do not confirm the latter view. In a brewery where the mash-tun wort is boiled in three "lengths," three samples of the wort drawn off from the tun were taken at different stages and analysed. Their respective specific gravities were 1095.8, 1070.2, and 1008.5, and their contents of protein ($N \times 6.25$) expressed as percentages of the extract present were 4.89, 5.45, and 8.97% respectively. It appears, therefore, that the matter extracted by the later spargings contains a considerably higher proportion of nitrogen than the extract in the first wort, but in view of the small amount of total extract in the last runnings the extra amount of nitrogenous matter introduced into the wort is almost negligible. The extract in the third sample was found to contain a rather larger proportion of "apparent dextrin," and a smaller proportion of "apparent maltose" than in the two other cases, though there was little difference between the specific rotatory powers of the three extracts. Analysis of the three successive copper worts, after boiling, showed substantially similar relations to those observed with the mash-tun worts.—J. H. L.

Beers ; Use of malt flour in the production of English —. F. Hyde. Amer. Brewers' Review, 1917, 31, 359.

In the preparation of English beers, using a highly attenuating yeast, the author has found certain advantages in the use of a dressing of malt dust made into small pellets and added to the wort during the primary fermentation when the yeast head is forming. About 1 lb. is used per 20 barrels of wort ; a small amount of sugar krausen is added at racking, the beer is fined and sent out 2 or 3 days later and usually consumed within 10 days. The practical advantages of the dressing

are better and more solid yeast crops, more complete attenuation, lessened liability of the beer to chill-haze, and enhanced head-retaining power. On the other hand there is a certain risk of infection since the malt dust contains bacteria, but this has been over-estimated. The alcohol-content of the beer is increased as a result of the dressing.

—J. H. L.

Alcoholic fermentation ; Intermediary reactions in —. H. Euler, H. Ohlsen, and D. Johansson. Biochem. Zeits., 1917, 84, 402—406.

A SWEDISH beer yeast dried at 40° C. and extracted with water gives an extract which contains a phosphatase capable of forming directly a phosphate ester from *lævulose* but not from dextrose. The latter sugar can, however, be esterified if it is first treated with fresh yeast. A yeast weakened by standing for six weeks in a solution containing sodium chloride and dextrose but no nitrogen, can also cause ester formation from phosphate and *levulose* but not from dextrose. The results confirm Harden's view that the hexose phosphate is a derivative of *lævulose* or a closely allied sugar, and that other sugars must be converted into this before esterification with the phosphate takes place.—S. B. S.

Lactose ; The formation of — from starch by the "loosened" ferments of sucrose serum. F. Röhmnn. Biochem. Zeits., 1917, 84, 399—401.

THE parenteral injection of sucrose into rabbits gives rise to special ferments in the serum ("her-vorgelockte Fermente"). The extract of the liver of a rabbit thus treated acts on soluble starch, causing degradation, and producing, amongst other products, lactose.—S. B. S.

Urease ; Preparation of — from bacteria. M. Jacoby. Biochem. Zeits., 1917, 84, 354—357. (See also this J., 1917, 663, 901, 1106.)

THE bacteria are removed from their cultures on agar and dried on porous porcelain. The preparation thus obtained is permanent and acts in the presence of toluene.—S. B. S.

Enzymes ; Formation of —. V. M. Jacoby. Biochem. Zeits., 1917, 84, 358.

LEUCINE inhibits rather than accelerates the action of urease (see preceding abstract) and this indicates, taken in conjunction with the author's previous work, that the amino-acid is necessary for the formation of the enzyme, but not for its action.—S. B. S.

XIXA.—FOODS.

Flour; Examination of "85%" — H. Delehay. *Ann. Falsif.*, 1917, 10, 554—558.

To determine whether a flour consists of 85% of the wheat grain the author suggests a method in which flour is passed through two sieves, Nos. 30 and 60 (Continental gauge); the portions retained by these two sieves are mixed, weighed, and the crude fibre content determined. Flours which conform with the 85% standard yield about 10% of coarse substance (on the two sieves), with a crude fibre content of 4%. In other flours the amount of coarse material falls as low as 4.5%, with a crude fibre content of 1%. The results obtained should be confirmed by a microscopical and chemical examination of the flour.—W. P. S.

Flour; Ratio of soluble nitrogen to total nitrogen in — E. Rousseaux and M. Sirot. *Ann. Falsif.*, 1917, 10, 556—560.

THE average ratio of soluble to total nitrogen in various flours is as follows:—Wheat, 6; maize, 5.5; rye, 4.4; bean, 8.2; barley, 8.2; rice, 23.6. When this ratio in the case of wheat flour is either above or below 6, the bread-making quality of the flour is unsatisfactory.—W. P. S.

Bread and flour; Poisonous — *Detection and determination of sapotoxins.* L. Stœcklin. *Ann. Falsif.*, 1917, 10, 561—572.

A SAMPLE of wheat examined by the author contained 19% of foreign seeds, including 10% of corn-cockle (*Agrostemma githago*). The toxic properties of the sapotoxins contained in the latter would explain the numerous cases of poisoning observed recently in France; it is possible that such samples of wheat are by no means rare. The hæmolytic action of sapotoxins is relied on for their detection, their quantity being determined by comparison with standards.—W. P. S.

"Sharps" and bran; Composition of — and *the effect thereon of the Food Controller's Orders.* H. E. Cox. *Analyst*, 1918, 43, 53—56.

THE composition of "sharps" (or middlings) and bran has been materially affected by recent orders of the Food Controller regarding the milling of wheat. To get the additional percentage of flour, a second grinding and sifting is necessary, and the "sharps" and bran suffer by loss of starchy material. The average yield of milling products of wheat at the present time is:—Government grade flour, 80; "sharps," 14; bran, 6%. The following table shows the alteration in the starch, pentosan, and crude fibre content of "sharps" and bran:—

	"Sharps."				Bran.	
	Pre-war		Present		Pre-war average.	Present average.
	Average.	Maximum.	Average.	Maximum.		
Crude fibre.....	6	7.5	8	10	9	13
Pentosan.....	12	18	17	20	20	24
Starch.....	32	Min. 25	25	Min. 18	15	14

Oat husk contains crude fibre 33, pentosans 40.4, and starch 3.27%.—W. P. S.

Wheat bran and its adulterants. E. Collin. *Ann. Falsif.*, 1917, 10, 539—551.

A DESCRIPTION is given of the microscopical appearance of wheat bran and of substances used to

adulterate it; among the latter are husks of other cereals, rice husk, earlhumt meal and husk, vegetable ivory, sawdust, castor oil seeds, maize husk, etc. The characteristic features of these are illustrated.—W. P. S.

Diphenylamine-sulphuric acid; Use of — *for colorimetric determinations [e.g., of nitrates in milk].* J. Tillmans. *Z. anal. Chem.*, 1917, 56, 509—511.

IN the method described previously by the author (this J., 1911, 44) for the determination of nitrates in milk, any variation in the intensity of the colorations obtained may be overcome by treating the test solution and the standards in exactly the same way.—W. P. S.

Margarine; Manufacture of — *in the United Kingdom.* W. G. Watson. *J. Roy. Soc. Arts*, 1918, 66, 212—220.

THE average weekly quantities of margarine manufactured in Great Britain increased from 1611 tons in 1913 to 3584 tons in 1917, whilst the imports of margarine increased from 1460 tons in 1913 to 2647 tons in 1916, and the weekly imports of butter decreased from 3980 tons in 1913 to 2092 tons in 1916. The churning process of 5 to 10 years ago has been replaced by a continuous process in which a motor-driven emulsifier, requiring little attention, is used. Arrangements are made to receive the milk in the factory within 6 to 8 hours after milking. The milk is separated (the cream being used for butter-making) and the skim milk is pasteurised, cooled nearly to freezing point, and stored in tanks under cold-storage conditions. The ripening process, by means of pure cultures of lactic organisms, is carried out in propagators continuously, the fresh milk being run in at the top as the ripened milk is drawn off at the bottom. Live steam has been found the most effective means of sterilising the plant. At Southall the air in the works is also purified, and brought to a constant temperature and humidity, by being drawn through a chamber, provided with means for heating or cooling, where it comes in contact with a fine rain produced by hundreds of water-jets. Thence it is distributed through the work-rooms by means of air-ducts. By aid of these precautions the keeping qualities of the margarine have been improved. (See also this J., 1918, 54 R.)—C. A. M.

Yeast as foodstuff. P. Petit. *Brasserie et Malterie*, 1917, 7, 257—260.

YEAST extracts intended for human consumption should possess a pleasant flavour, resembling that of meat extract, without sourness or bitterness;

they should keep well in closed bottles and if possible be dark in colour. The following method of preparation is described. Carefully sifted and well washed yeast is treated first with a 0.1—0.15% solution of sodium or ammonium carbonate and then with a similar solution of half this concentration. Thus freed from bitter resins, the

pressed yeast is liquefied by admixture with 10% of sodium chloride and a little water, the mixture being maintained meanwhile at 40°–45° C., in a shallow pan. After liquefaction flavouring vegetables such as celery, onions, or leeks may be added, and the mixture is heated at 70°–75° C., exposed to the air in a shallow pan, until the required "meaty" flavour and dark colour have developed. The temperature may then be raised to the boiling point for a moment. After the insoluble matter has been removed by filtration or subsidence, the clear extract is concentrated in steam-jacketed pans and filled into sterile bottles, and if necessary pasteurised. Products of high nutritive value may be obtained by mixing concentrated, unhopped malt wort with extracts made from yeast which has been liquefied with sugar instead of salt. A less known type of product is flaked yeast extract. To prepare this the purified yeast is liquefied with a small quantity of salt and the subsequent heating is limited to 30°–35° C. to avoid darkening the colour. The filtered extract is concentrated at a low temperature, *in vacuo*, and converted into flakes by passage between heated rollers. The dried product keeps almost indefinitely and is said to have a nutritive value three times as great as that of meat.

—J. H. L.

"Syrup; Nitrogen —." E. Jalowetz. Brau- und Malzind., 1916, 17, 247. Z. ges. Brauw., 1917, 40, 118.

WHEN concentrated sucrose solutions are digested with washed brewers' yeast for 3–4 hours at 53°–54° C., partial inversion of the sugar takes place, and by subsequent concentration syrups containing 2% or more of protein may be obtained resembling malt extracts in appearance and flavour.—J. H. L.

Antineuritic properties of the infusorial earth extract of the hydrolysed extract of rice polishings. H. C. Brill. Philippine J. Sci., 1917, 12a, 199–206.

ONLY a portion of the vitamin content of the hydrolysed extract of rice polishings is extracted by infusorial earth, used in the proportion of 50 grms. of earth to 500 c.c. of extract. The extract appears to lose its antineuritic properties as it ages.—W. G.

Gossypol, the toxic substance in cottonseed. W. A. Withers and F. E. Carruth. J. Agric. Res., 1918, 12, 83–102.

FURTHER feeding experiments (compare this J., 1915, 1267) have been conducted with rats, rabbits, and pigs. Cottonseed meal is much less toxic than raw cottonseed, probably owing to oxidation of the gossypol during the cooking in the preparation of the meal. Feeding experiments with small pigs in pens showed that cottonseed meal is definitely injurious but that the ether-extracted raw seed does not appear to cause cottonseed meal poisoning. Gossypol is toxic to pigs. In addition to this toxic effect a diet of cottonseed meal and corn (maize) meal has nutritive limitations which may lead to failure of pigs to thrive in pens, this result being, however, quite distinct from cottonseed meal poisoning. This poisoning may be postponed or averted in the case of pigs by outdoor exercise, access to forage and soil, and improved diets.—W. G.

Malt meal; Rearing of young pigs on —. Richardson. Biedermann's Zentr., 1918, 47, 43–47.

YOUNG pigs grew rapidly on a diet in which a large proportion of the milk was replaced by "cerealis," a malt meal containing 12.6% protein, 2.7% fat, 27.2% maltose, 27.6% starch, 3.8% fibre, 3.0% ash, and 9% moisture. Although

"cerealis" is not now obtainable, similar results may be expected to follow the use of auto-digested malt for this purpose.—H. W. B.

Casein; Effect of time of digestion on the hydrolysis of — in the presence of starch. J. S. McHargue. J. Agric. Res., 1918, 12, 1–7.

THE Van Slyke method for protein analysis (this J., 1911, 1135), when applied to a mixture of casein and starch in the proportion of 1 to 5, the hydrolysis being carried on for 12–15 hours with 20% hydrochloric acid, gives results for the amino-acid groups comparable with those obtained for casein alone. Prolonging the time of hydrolysis with the casein-starch mixture causes a redistribution of the nitrogen in the histidine and cystine groups. The insoluble residue from the casein-starch hydrolysis contains nitrogen, which is in an inert form and should not be included in the humin determination.—W. G.

Use of different alkalis in quantitative analysis. Palet. See XXIII.

PATENTS.

Milk; Drying —. C. H. Campbell, Assignor to Borden's Condensed Milk Co., New York. U.S. Pat. 1,250,127, Dec. 18, 1917. Date of appl., Dec. 29, 1913.

MILK is concentrated, then converted into an aerated, plastic, adhesive mass which is spread on a flexible wire net and dried by passing it between a pair of hot-air boxes.—W. P. S.

Liquids [milk]; Apparatus for treating —. C. H. Campbell, Assignor to Borden's Condensed Milk Co., New York, N.Y. U.S. Pat. 1,253,317, Jan. 15, 1918. Date of appl., Jan. 7, 1916.

THE apparatus consists of a trough-shaped vessel containing a horizontal shaft on which agitators are mounted. Air is admitted by a series of pipes placed alternately on each side of the trough between the agitators, and reaching towards the bottom of the trough. In a form of the apparatus specially designed for the treatment of milk, the shaft is hollow and is divided lengthwise into a supply and an exhaust compartment, with an opening into each at opposite ends of the shaft. The agitators are hollow discs tapering towards their peripheries. From the supply compartment of the shaft, a pipe opens into each disc towards the apex, and opposite to it is placed an outlet pipe leading into the exhaust compartment. Scrapers are provided for the discs during rotation. A liquid at a suitable temperature may be passed through the discs.—J. H. J.

Grain and other coarse granular materials; Process for drying —. E. Passburg, Berlin. U.S. Pat. 1,250,496, Dec. 18, 1917. Date of appl., Nov. 9, 1916.

THE grain is stirred and heated to 60°–70° C., then transferred to a non-heated vessel, and dried therein first under slightly and then under greatly reduced pressure.—W. P. S.

Egg preservative. M. J. Davis, Brooklyn, N.Y., Assignor to M. Micolino, New York. U.S. Pat. 1,250,567, Dec. 18, 1917. Date of appl., June 2, 1915. (See also Eng. Pat. 105,840 of 1916; this J., 1917, 665.)

TUNG oil or a mixture of tung oil and resin is used for coating the eggs.—W. P. S.

Meats; Duplex process for smoke-curing —. A. C. Legg, Birmingham, Ala. U.S. Pat. 1,250,934, Dec. 18, 1917. Date of appl., Dec. 14, 1915.

MEAT is dried in an upward current of hot dry

smoke until the fat begins to shrink, and then in a down draught of cool smoke from which "the products of active combustion" are excluded.

—W. P. S.

Fish; Process of preserving—and products thereof. R. M. Thompson, Tacoma, Wash. U.S. Pat. 1,252,865, Jan. 8, 1918. Date of appl., Nov. 26, 1917.

Fish of the shark family is cooked in a retort and the exuded juice withdrawn; a vacuum is then produced in the retort and the fish drained. Next an acid fluid is introduced and allowed to impregnate the fish, after which a partial vacuum is again produced in order to remove some of the moisture. The meat is then separated from the bone and canned. The product may be flavoured with the flavours of other meats.—J. H. J.

Lubrication of milk centrifugals and the like. H. Holte, and Aktieselskapet Separator, Skien, Norway. Eng. Pat. 111,662, Nov. 9, 1917. (Appl. No. 16,427 of 1917.) Under Int. Conv., Nov. 28, 1916.

Preparation of colouring bodies for use in food, pharmaceutical and other preparations. Eng. Pat. 112,886. See IV.

Method of manufacturing radioactive mineral water salts. U.S. Pat. 1,253,830. See VII.

Water; Means for rendering — radio-active. G. E. Heyl and T. T. Baker, London. Eng. Pat. 112,865, Mar. 30, 1917. (Appl. No. 4651 of 1917.)

A SMALL quantity of a solid radio-active compound, such as radium-barium sulphate of about 1 : 1,000,000 concentration, which has been ground to a very fine powder under water, is contained within a capsule of a material soluble in water, such as gelatin and the like. When placed in water, the capsule dissolves, releasing an infinite number of excessively small radio-active particles.

—L. A. C.

Waters; Method for treating ferruginous —. L. S. Hughes and C. H. Wolcott, Chicago, Ill. U.S. Pat. 1,254,009, Jan. 15, 1918. Date of appl., Sep. 8, 1914.

A FERRUGINOUS water is treated with a soluble hypochlorite to convert ferrous salts into ferric salts, and then neutralisation is commenced with a compound which will form an insoluble salt with the acid content of the water, and completed with magnesite. The precipitate is recovered.—J. H. J.

Water and other liquids or the like; Filtering of —. D. Dunbar, Glasgow. U.S. Pat. 1,253,674, Jan. 15, 1918. Date of appl., Aug. 19, 1914.

SEE Eng. Pat. 19,142 of 1913; this J., 1914, 980.

Water; Process for the elimination of manganese and iron from —. V. Kobelt, Berlin-Schöneberg, Germany. U.S. Pat. 1,253,840, Jan. 15, 1918. Date of appl., Jan. 21, 1915.

SEE Eng. Pat. 405 of 1915; this J., 1916, 326.

XX.—ORGANIC PRODUCTS ; MEDICINAL SUBSTANCES ; ESSENTIAL OILS.

Morphine alkaloids; Constitution of the —. Synthesis of isoquinoline derivatives. H. A. Kaufmann and N. Dürst. Ber., 1917, 50, 1630—1637. (Compare J. Chem. Soc., 1916, i., 502.)

ACCORDING to the commonly-accepted constitution of the morphine alkaloids, these bases do not contain the isoquinoline ring but a special nitrogen-ring of their own, which, however, may be ruptured and the free chain closed up again into an isoquinoline nucleus. This is illustrated by the change from morphine to apomorphine, brought about by heating with zinc chloride solution or concentrated hydrochloric acid:—

The free chain, existing for a moment after the rupture of the "morphine ring," might be $\cdot N(CH_3) \cdot CH_2 \cdot CH_2 \cdot OH$, and accordingly, the authors have attempted to bring about the condensation of piperonyl- β -hydroxyethylmethylamine,

$CH_2 : O_2 : C_6H_4 \cdot CH_2 \cdot N(CH_3) \cdot CH_2 \cdot CH_2 \cdot OH$, which contains this side-chain, to dihydrohydrastinine,

Unlike the tertiary phenylethylamine,

$CH_2 : O_2 : C_6H_4 \cdot (CH_2)_2 \cdot N(CH_3) \cdot CH_2 \cdot OH$,

however, piperonyl- β -hydroxyethylmethylamine (a tertiary benzylamine) does not yield an isoquinoline derivative. This is probably due to the fact that tertiary benzylamines readily decompose into benzyl alcohol and secondary amines. Piperonyl- β -hydroxyethylmethylamine is prepared by condensing piperonemethylamine with ethylene oxide.—J. C. W.

Butyric acid; Detection and determination of —. G. Deniges. Ann. Chim. Analyt., 1918, 23, 27—31.

FIVE c.c. of butyric acid solution is mixed with 5 c.c. of hydrogen peroxide solution (0.1 vol. strength for 0.01 % butyric acid solution or 5 vols. for a 0.5 % butyric acid solution) and 1 c.c. of ferrous ammonium sulphate solution (5 grms. of ferrous ammonium sulphate and 10 c.c. of 10 % sulphuric acid per 100 c.c.), and the mixture is heated at 70° C. for 5 mins., 6 drops of sodium hydroxide solution are then added, the mixture is cooled rapidly, filtered, and 5 c.c. of the filtrate is treated with 3 drops of sodium hydroxide solution and 3 drops of 5 % sodium nitroprusside solution. After shaking, the mixture is rendered acid with acetic acid. The intensity of the red coloration (due to acetoacetic acid) which develops is proportional to the quantity of butyric acid present and the amount of the acid may be ascertained by comparison with standards. When present in complex mixtures, the acid must first be separated by distillation or extraction.—W. P. S.

Lactic acid; Determination of — in the presence of other organic acids. P. Szeberényi. Z. anal. Chem., 1918, 56, 505—506.

ON oxidation with chromic acid, lactic acid yields acetic acid, carbon dioxide, and water, whilst

other organic acids, such as tartaric, citric, malic, and oxalic acids give only carbon dioxide and water. After volatile substances (volatile acids, alcohol, esters, etc.) have been distilled off, a portion of the residual solution corresponding with about 40 c.c. of *N*/1 sodium hydroxide solution is treated with 30 c.c. of 50% chromic acid solution and 20 c.c. of dilute sulphuric acid, the mixture is diluted to 100 c.c., boiled under a reflux condenser for 15 mins., cooled, and the acetic acid formed is separated by distillation, and titrated. About 3% of the lactic acid present is destroyed completely by the oxidation and the results calculated from the acetic acid found, are correspondingly low. A small portion of the lactic acid distils over with the volatile acids. If only acetic and formic acids are also present, it is possible to determine this quantity of lactic acid by titrating the distillate and determining the molecular equivalents of the acids in the usual way; the formic acid, must, of course, be determined separately. (See also *J. Chem. Soc.*, Mar., 1918.) —W. P. S.

Chaulmoogra oil; Use of — as a specific for leprosy. H. C. Brill and R. R. Williams. *Philippine J. Sci.*, 1917, 12A, 207—220. (See also this *J.*, 1901, 669; 1907, 420.)

TEN samples of chaulmoogra oil from various sources were examined and found to have the following physical characters:—

	Maximum.	Minimum.	Average.
Sp. gr. at 30° C.	0.9535	0.9429	0.9471
[α] _D in chloroform ..	+58.20°	+45.69°	+50.81°
Acid value (c.c. of <i>N</i> /10 alkali)	21.48	1.55	6.79
Saponification value ..	210.5	189.1	200.4
Refractive index	1.4774	1.4720	1.4751
Iodine value	110.4	97.6	102.4

The mixed free acids from two samples had [α]_D²⁰ = +54.00° and +47.40° (in chloroform); iodine value, 101.3 and 99.7; acid value 35.31 and 34.95 c.c. *N*/10 alkali; m.p. 38°—39° and 39°—40° C. The chaulmoogric and hydnocarpic acids were isolated and their physical constants were as follows:—For chaulmoogric acid, saponification value, 200.5—202.4; [α]_D²⁰ +59.05° and +58.10° (in chloroform); iodine value 89.5—90.7; for hydnocarpic acid, saponification value, 222.7—218.2; [α]_D²⁰ = +67.70° and +67.60° (in chloroform); iodine value, 100.2—99.9. A sample of oil from the seeds of *Hydnocarpus anthelmintica* had sp. gr. at 30° C. 0.9487; [α]_D²⁰ = +49.50° (in chloroform) acid value, 0.6 c.c. of *N*/10 alkali; saponification value, 206.2; refractive index, 1.4725; iodine value, 90.8. The use of various fractions of chaulmoogra oil in leprosy is discussed.—W. G.

Essential oils; Determination of alcohols in —. T. T. Cocking. *Perfum. and Essen. Oil Record*, 1918, 9, 37—38.

A FORMULA is given by which the amount of free alcohol may be determined in the presence of any ester or mixture of esters provided that these are not affected by acetylation. Let *a* be the saponif. value of the original oil, *b* the saponif. value of the oil after acetylation, and *y* the molecular wt. of the alcohol (if monohydric), then percentage of free alcohol is
$$\frac{(b-a)y}{0.42016(1335.5-b)}$$
 —W. P. S.

Chloral hydrate, chloral syrup, etc.; Analysis of —. M. François. *Ann. Palsif.*, 1917, 10, 575—581.

A METHOD for determining chloral hydrate depends on the reaction of this substance with sodium

hydroxide: $\text{CCl}_3\text{CHO} + \text{H}_2\text{O} + \text{NaOH} = \text{CHCl}_3 + \text{HCOONa} + \text{H}_2\text{O}$. Provided that the solution is dilute and the time of contact short, secondary reaction between the alkali and chloroform does not take place to any appreciable extent. About 2 grms. of the chloral hydrate is dissolved in 200 c.c. of water, a slight excess of *N*/1 sodium hydroxide is added, and, after 1 min., the mixture is titrated with *N*/1 sulphuric acid, using phenolphthalein as indicator. Each c.c. of *N*/1 sodium hydroxide solution used is equivalent to 0.1655 gm. of chloral hydrate. With pure chloral hydrate the results obtained by the method vary from 99.7 to 100.1%.—W. P. S.

Carbamides; Constitution of —. V. Mechanism of the decomposition of urea when heated in solution with alkalis and with acids respectively. Hydrolysis of metallic cyanates. E. A. Werner. *Chem. Soc. Trans.*, 1918, 113, 84—99.

THE decomposition of urea on heating with acids or alkalis in aqueous solution is primarily dependent on its dissociation into ammonia and cyanic acid. Its so-called "hydrolysis" is only the hydrolysis of cyanic acid or of an alkali cyanate, and is therefore not a change which gives any support to a "carbamide" structure. Owing to the proportion of free urea being greater in presence of sodium hydroxide than in presence of hydrochloric acid, under comparable conditions the velocity of decomposition is greater in the former case. The ionisation suggested by Masson (*Z. physik. Chem.*, 1910, 70, 290) fails to explain the conversion of ammonium thiocyanate into urea or the formation of urea during the hydrolysis of cyanic acid or metallic cyanates, and is not in agreement with the facts. The acceleration of the conversion of ammonium cyanate into urea and the retarding of the decomposition of urea in solution by alcohol are readily explained by and are in complete agreement with the dissociation theory. A sterilised solution of urea does not undergo any "hydrolysis" or reversion to ammonium cyanate at the ordinary temperature; the latter can only arise from the dissociation of the urea as a preliminary stage.—F. W. A.

Antineuritic properties of the infusorial earth extract of the hydrolysed extract of rice polishings. Brill. See XIXA.

Use of different alkalis in quantitative analysis. Palet. See XXIII.

PATENTS.

Larrea Mexicana or Hedionda; Process of making and extracting the medicinal properties of the —. C. R. Blundell, Assignor to W. J. Bryan, jun., Tucson, Ariz. U.S. Pat. 1,250,132, Dec. 18, 1917. Date of appl., July 17, 1917.

THE ground pulp of *Larrea Mexicana* is saturated with paraffin oil (sp. gr. 0.9), submitted to direct solar rays for 12 hours, heated to 212° F. (100° C.) for 2 hours, and cooled to 80° F. (27° C.). The mixture is then pressed, and freed from resinous solids by centrifuging.—J. H. J.

Tuberculosis, leprosy, and other diseases; Substance for treatment of — and process of mixing said substance. B. S. Paschall, Seattle, Wash. U.S. Pat. 1,250,345, Dec. 18, 1917. Date of appl., May 1, 1917.

THE wax elaborated by tubercle and other acid-fast bacilli is saponified, and an alcohol, a hydrocarbon, and a fatty acid are separated from the products obtained. These three products are then esterified and the esters mixed together. The mixture obtained is claimed to have a therapeutic action upon a host harbouring acid-fast bacilli when administered parenterically.—J. H. J.

Chlorhydrins; Manufacture of —. K. P. McElroy, Assignor to Chemical Development Co., Washington. U.S. Pat. 1,253,615, Jan. 15, 1918. Date of appl., June 22, 1915.

A BATH containing a chloride in solution is treated with oil-gas and a current passed through an anode and cathode in the bath, and through a secondary cathode separated from the bath by a diaphragm. Limited oxidation takes place at the anode, the presence of water preventing the formation of olefine chlorides to any considerable extent. The process applies also to the formation of other halogen-hydrins. A solvent for cellulose esters is composed of the chlorhydrins corresponding to the gaseous olefines of oil-gas, the liquid being heavier than water, boiling in the dry state between 125° and 135° C. in the moist state, below 100° C., and being miscible with several times its volume of water.—L. A. C.

Chlorhydrins; Process of making —. K. P. McElroy, Assignor to Chemical Development Co., Washington. U.S. Pat. 1,253,616, Jan. 15, 1918. Date of appl., June 17, 1915.

A MIXTURE of steam and oil gas is blown through a horizontal chamber, maintained at about 100° C.; the chamber is provided with baffles, to cause the mixture to take a circuitous path, and successive quantities of chlorine gas are also passed in. At the bottom of the chamber is a quantity of boiling water which absorbs the hydrochloric acid formed, and which is maintained at a low concentration. The hot vapours are condensed to obtain the chlorhydrin.—L. A. C.

Oxidising hydrocarbons; Process of and apparatus for —. K. P. McElroy, Assignor to Chemical Development Co., Washington. U.S. Pat. 1,253,617, Jan. 15, 1918. Date of appl., Aug. 2, 1912.

A GASEOUS olefinic hydrocarbon (e.g., ethylene) is subjected to limited anodic oxidation, the hydrocarbon being maintained in excess in the sphere of reaction.—L. A. C.

Anæsthetic bodies. Parke, Davis and Co., Assignees of L. Thorp, Detroit, Mich., and E. A. Wildman, Indianapolis, Ind., U.S.A. Eng. Pat. 105,745, Feb. 27, 1917. (Appl. No. 2921 of 1917.) Under Int. Conv., Apr. 17, 1916.

Preparation of colouring bodies for use in food, pharmaceutical or other preparations. Eng. Pat. 112,886. See IV.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photography; Colloid chemistry and —. Lüppo-Cramer. Kolloid-Zeits., 1917, 21, 154—155.

PHOTO-MICROGRAPHS of silver chloride crystals, which have been exposed to sunlight, exhibit a very large number of dark points which are considered to be due to aggregates of silver particles.

The pressure developed by the corresponding chlorine leads to disturbances in the crystalline structure which result in disintegration.—H. M. D.

PATENT.

Sensitised [photographic] plates; Drier for —. L. McCue, Assignor to F. L. Harwood, R. W. Albertson, J. H. Gilson, and N. M. Whipple, Chicago, Ill. U.S. Pat. 1,253,990, Jan. 15, 1918. Date of appl., Mar. 19, 1914.

THE device includes a drying chamber, the bottom of which is heated from below and is covered with sand for even distribution of the heat, and an arrangement for keeping the plates in the drying chamber in motion.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Cellulose; Nitration of cotton —, and influence of prolonged bleaching on its transformation into dinitrocellulose. R. Namias. Monit. Scient., 1918, 8, 5—6.

IN a series of experiments, 5 grms. of cotton of the best quality was nitrated in 200 grms. of a bath containing 60% of sulphuric acid, 24% of nitric acid, and 16% of water, for periods of 2, 4, 12, and 24 hours at 18° C. The nitrogen content of the four products was practically identical, viz., 11.80% to 11.92%, and all were completely soluble in ether-alcohol. The fibre is appreciably weakened if nitration is continued much beyond two hours, or if higher temperatures are employed, and the nitrocellulose is less suitable for making collodion, or for coating incandescent mantles, etc. All the samples burnt instantaneously without leaving a residue. Cotton which had received excessive chlorine treatment showed no difference under the microscope and gave no evidence of tendering, but when nitrated under the same conditions, the percentage of nitrogen in the products varied from 9.80% to 10.37%, and the solubility in ether-alcohol was incomplete. A residue was left on burning, indicating the presence of unnitrated cotton. The author suggests that this may be due to the presence of oxycellulose in the over-bleached cotton.—F. Sp.

PATENTS.

Explosive compositions; Production of —. Commercial Research Co., Long Island City, N.Y., Assignees of H. Hibbert, Pittsburgh, Pa., U.S.A. Eng. Pat. 106,086, Feb. 8, 1917. (Appl. No. 1964 of 1917.) Under Int. Conv., Apr. 17, 1916.

SEE U.S. Pat. 1,231,351 of 1917; this J., 1917, 943.

Explosive substance. C. R. Jahn, Schlebusch, Assignor to Sprengstoff A.-G. Carbonit, Hamburg, Germany. U.S. Pat. 1,253,691, Jan. 15, 1918. Date of appl., Dec. 15, 1913.

SEE Eng. Pat. 18,333 of 1914; this J., 1915, 935.

XXIII.—ANALYSIS.

Alkalis in quantitative analysis; Use of different —. L. P. J. Palet. Ann. Chim. Analyt., 1918, 23, 26—27.

ATTENTION is directed to the necessity of using one and the same alkali for certain determinations in order to obtain concordant results. For instance, in the determination of caffeine in maté,

with calcium oxide as the alkali 0.790% of caffeine was found, with magnesium oxide 0.780%, and with ammonia 0.090%. The difference in the action of alkalis is still more marked in the case of aqueous solutions containing albumin, asparagine, peptone, or urea, *e.g.*, in the case of sewage effluents.—W. P. S.

Sulphuric acid and barium; Gravimetric determination of — as barium sulphate. Z. Karaoglanow. Z. anal. Chem., 1917, **56**, 487—498.

THE presence of nitric acid or a large quantity of hydrochloric acid causes the results obtained in this determination to be too low; potassium salts and ferric chloride have the opposite effect, the results being too high. The conditions of experiment being equal, the errors produced by the presence of the above substances are always less in the determination of barium than in that of sulphuric acid. (See also J. Chem. Soc., Mar., 1918.)—W. P. S.

Potassium and sodium as chlorides; Determination of — through the use of the refractometer. B. A. Shippey and G. H. Burrows. J. Amer. Chem. Soc., 1918, **40**, 185—187.

A METHOD for the determination of potassium and sodium as chlorides in the presence of each other depends on the fact that the refractive index of sodium chloride solution is higher than that of a corresponding potassium chloride solution; the difference increases with increase in salt concentration. The refractive indices at 25° C. of 20% potassium chloride and sodium chloride solutions are 1.35992 and 1.36829, respectively. To determine the proportion of potassium and sodium in a mixture of the two chlorides, a 20% solution of the latter is prepared and the refractive index observed; the amounts of the two salts are then found by simple calculation. The method does not possess a high degree of accuracy. (See also J. Chem. Soc., Mar., 1918.)—W. P. S.

Potassium; Gravimetric determination of — by sodium cobaltinitrite. C. V. Garola and V. Braun. Ann. Falsif., 1917, **10**, 572—575.

THE solution of the potassium salt, containing about 0.25 gm. of potassium chloride and free from other bases except sodium, is evaporated to 25 c.c. and treated with 25 c.c. of sodium cobaltinitrite solution (cobalt nitrate, 28.6 grms., glacial acetic acid, 50 c.c., sodium nitrite, 180 grms., water to 1000 c.c.). After 18 hrs., the precipitate is collected, washed with 10% acetic acid, then once with 95% alcohol, dried at 100° C. and weighed. The weight is multiplied by 0.2074 to obtain the quantity of K₂O present. The method is accurate and may be applied to fertilisers, soils, wines, etc.—W. P. S.

Acidity determination in waters, leach liquors, mine waters, etc. J. J. Rankin. Met. and Chem. Eng., 1918, **18**, 96.

THE accurate titration with sodium carbonate of acidic liquors containing sulphates of ferric iron, copper, aluminium, and manganese is impossible owing to the ill-defined end point. This difficulty can be avoided by a reduction of ferric to ferrous sulphate with potassium iodide, the iodine liberated being removed by addition of the proper quantity of sodium thiosulphate. Cupric sulphate is reduced to cuprous iodide which is precipitated, and the iodine liberated is discharged in the same way. In practice a convenient quantity of the liquor is diluted to 250 c.c. and an excess of potassium iodide added. Sodium thiosulphate

(10%) is added until the iodine colour is nearly discharged, and the solution made up to a definite volume. An aliquot part is taken and more sodium thiosulphate added until the colour is finally discharged, when the titration with standard soda can be made, using methyl orange as indicator. Chlorides and nitrates do not interfere nor does aluminium sulphate if sufficient ferrous iron is present.—H. J. II.

Copper group from the arsenic group; Separation of the — with special reference to the identification of arsenic. M. C. Sneed. J. Amer. Chem. Soc., 1918, **40**, 187—191.

THE mixed sulphides are digested with a reagent prepared by saturating a 12% sodium hydroxide solution with hydrogen sulphide and adding to each litre 400 c.c. of 40% sodium hydroxide solution. Mercuric, arsenic, antimony, and tin sulphides dissolve, whilst lead, bismuth, copper, and cadmium sulphides remain insoluble. The latter are separated by filtration. The filtrate is treated with a quantity of ammonium carbonate sufficient to precipitate the mercury completely, and, after this has been removed, the solution is acidified with hydrochloric acid. The precipitated arsenic, antimony, and tin sulphides are collected, treated with 20 c.c. of concentrated hydrochloric acid, and the mixture is warmed until vigorous evolution of hydrogen sulphide ceases. Arsenic sulphide is not dissolved by this treatment; after the solution containing the tin and antimony sulphides has been separated, the arsenic sulphide is dissolved in ammonia and the solution neutralised with nitric acid; a yellow precipitate forms which is dissolved by boiling with nitric acid, and the solution is treated at 85° C. with an excess of ammonium molybdate. With a large amount of arsenic, a yellow precipitate forms at once, but with traces half an hour's heating may be required to obtain a precipitate. (See also J. Chem. Soc., Mar., 1918.)—W. P. S.

Zinc; Determination of — by Schaffner's method. V. Hassreidter. Z. anal. Chem., 1917, **56**, 506—509.

THE preliminary separation of the iron, whether by one or more precipitations by ammonia as prescribed in the various modifications of this method, should be made under conditions which prevent as far as possible the occlusion of zinc in the precipitate; the quantity of ammonia used must not be too small. The iron precipitate should be tested for zinc, and a control precipitation with known amounts of iron and zinc should be made at the same time and under the same conditions. (See also J. Chem. Soc., Mar., 1918.)—W. P. S.

Gas analysis; Applications of —. IV. The Haldane gas analyser. Y. Henderson. J. Biol. Chem., 1918, **33**, 31—38.

MODIFICATIONS of Haldane's apparatus for the estimation of carbon dioxide in air and in blood are described, by means of which the apparatus may be more readily taken apart and cleaned. (See also J. Chem. Soc., Mar., 1918.)—H. W. B.

Nitrogen; Microchemical estimation of —. B. Sjollesma and C. W. G. Hatterschy. Biochem. Zeits., 1917, **84**, 359—370.

A CRITICAL examination of the methods of Bang and of Folin and Denis (this J., 1916, 1133), with some suggested minor alterations in the details. (See also J. Chem. Soc., Mar., 1918.)—S. B. S.

Determination of total carbon in fuels and its importance in the study of fuel economy. Damour and De la Morinière. See IIA.

Detection of selenium in sulphuric acid. Palet. See VII.

Determination of silicon in ferrosilicon. Nicolardot and Koenig. See X.

Filtration of silica [in analysis]. Nicolardot and Koenig. See X.

Tentative standard methods for sampling and analysis of commercial fats and oils other than those of the coconut, butter, and linseed groups. See XII.

Determination of ash in leather. Riethof and Gayley. See XV.

New method for estimation of "zeolitic" silicic acid in soils. Guedroitz. See XVI.

Determination of phosphoric acid, particularly in superphosphate. Vortmann. See XVI.

Some methods for determination of sucrose content of [cane] molasses. Van der Linden. See XVII.

Estimation of phosphorus, hypophosphoric, and phosphoric acid in mixtures. Van Name and Hull. See VII.

Dry substance and sucrose determinations in cane molasses. Steuerwald. See XVII.

Examination of "85%" flour. Delehayé. See XIX.

Poisonous bread and flour. Detection and determination of sapotorins. Stoecklin. See XIX.

Use of diphenylamine-sulphuric acid for colorimetric determinations [e.g., of nitrates in milk]. Tillmans. See XIX.

Effect of time of digestion on the hydrolysis of casein in presence of starch. McHargue. See XIX.

Detection and determination of butyric acid. Denigès. See XX.

Determination of lactic acid in presence of other organic acids. Szeberényi. See XX.

Determination of alcohols in essential oils. Cocking. See XX.

Analysis of chloral hydrate, chloral syrup, etc. François. See XX.

PATENTS.

Gas-testing apparatus. H. R. Webster, Horsforth. U.S. Pat. 1,252,975, Jan. 8, 1918. Date of appl., June 29, 1917.

See Eng. Pat. 107,811 of 1916; this J., 1917, 980.

Method of and means for indicating the condition of steel, iron, or other magnetisable metal during heat treatment. Eng. Pat. 112,891. See X.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Akt.-Ges. Brown, Boveri, et Cie. Operating surface condensing-plant by steam-jet air pumps. 4346. Mar. 12. (Switzerland, June 25, 1917.)

Bingham, and Huntington, Heberlein, and Co. Apparatus for electrical separation of suspended particles from gaseous bodies. 3842. Mar. 5.

Brackett, and Brackett and Co. Screening or filtering apparatus. 3781. Mar. 1.

Broadley. Machines for grinding ores, minerals, stones, etc. 4303. Mar. 12.

Dibdin. Vaporisation of liquids or generation of gases by action of liquids on other matter. 4526. Mar. 14.

Dunsford and Linley. Refrigerating-apparatus. 4561. Mar. 14.

Harrison. 3823. See VIII.

Harvey, and Harvey Gas Furnace Co. 3857. See II.

Harvey, and Morgan Crucible Co. 4682. See X. Hewett. Drying fruit, liquids, chemicals, etc. 3877. Mar. 5.

Howe. Method of obtaining motive power. 4394. Mar. 13.

Hutchins. Means for drying gases. 4443. Mar. 13.

Hutchins. Drying, etc., apparatus. 4444. Mar. 13.

Killburn (Sulzer Frères). Cooling hot residues from distillation processes. 3997. Mar. 7.

Quinan. Means for elevating liquids. 3930. Mar. 6.

Quinan. Production of chemical reactions. 4343. Mar. 12.

Saunders. Utilisation of heat of gaseous fluids. 4261. 4262. Mar. 11.

Slocum. Process of treating material with gas or vapour. 4452. Mar. 13.

Slocum. Apparatus for treating material with gas or vapour. 4453. Mar. 13.

Stockel. Refrigerating-machines. 4322. Mar. 12.

Stutz. Apparatus for treating material with gas or vapour. 4456. Mar. 13.

Talbot. Means for purifying air. 4196. Mar. 9.

Tuckley. Grinding-machines. 3855. Mar. 5.

Turrettini. Generating heat by chemical reaction. 4011. Mar. 7. (Switzerland, July 17, 1917.)

Williams. Motive power plant. 4563. Mar. 14.

COMPLETE SPECIFICATIONS ACCEPTED.

17,366 (1916). Marlow, and Minton, Hollins, and Co. See VIII.

3192 (1917). Bamberg. Grinding-machines. (113,677.) Mar. 13.

4255 (1917). Simon-Carves, Ltd., and Brown. See II.

1686 (1917). Hilger, Ltd., and Merton. See XXIII.

16,744 (1917). Thuman (Crisfield). See II.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Beilby. Carbonisation of coal, shale, peat, wood, etc. 4287. Mar. 12.

Bouillon. Treating peat. 4622. Mar. 15.

Brooke, and Dempster and Sons. Horizontal and inclined retort settings. 4504. Mar. 14.
 Dempster and Sons, and Toogood. Heating horizontal retorts for gas production. 4203. Mar. 11.
 Dibdin. 4526. *See I.*
 Dobson and Pickard. Gas-producers. 4588. Mar. 15.
 Dobson and Pickard. Combustible gases. 4589. Mar. 15.
 Easton. Retorts, coke-ovens, etc. 4525. Mar. 14.
 Garbarini, Gautier, and Maclaure. Arc lamps. 3913. Mar. 6. (France, Oct. 13, 1917.)
 Hannay. Apparatus for obtaining mixtures of constant composition by evaporation of volatile combustibles by air or gases. 3759. Mar. 4.
 Harvey, and Harvey Gas Furnace Co. Regenerative gas furnaces. 3857. Mar. 5.
 Hopkins. Manufacture of composition fuel. 4249. 4626. Mar. 11 and 15.
 Hutchins. 4443. *See I.*
 Kilburn (Sulzer Frères). 3997. *See I.*
 Maxon. Combustion of gas. 4543. Mar. 14.
 Miller. Combustion of solid fuel in boiler, etc., furnaces. 4259. Mar. 11.
 Morris. System of supplying explosive mixture to internal-combustion engines for vehicles by self-contained producer-gas plants. 3755. Mar. 4.
 Rideal and Taylor. 4532. *See VII.*
 Saunders. 4261. 4262. *See I.*
 Spicer (Wells). Production and treatment of gas. 4673. Mar. 16.
 Turrettini. 4011. *See I.*
 Walker. 3733. *See VII.*

COMPLETE SPECIFICATIONS ACCEPTED.

11,574 (1916). Riedel. Method for preventing the choking-up of gas plant. (101,219.) Mar. 20.
 17,161 (1916). Hamburger, Lely, and Naanil. Vennoots. Philips' Gloeilampenfabrieken. Electric incandescent lamps. (113,626.) Mar. 13.
 2983 (1917). Rose. Process of manufacturing gaseous fuel. (113,657.) Mar. 13.
 3962 (1917). Wollaston. Gas-generators. (113,856.) Mar. 20.
 4255 (1917). Simon-Carves, Ltd., and Brown. Gas-fired coke ovens and muffle and like furnaces. (113,696.) Mar. 13.
 7084 (1917). Alldays and Onions Pneumatic Engineering Co., and Allday. Apparatus or furnaces for gasifying or vaporising liquid fuel. (113,717.) Mar. 13.
 11,032 (1917). Sugimoto. *See X.*
 16,744 (1917). Thuman (Crisfield). Gas washer scrubbers. (113,937.) Mar. 20.
 19,288 (1917). Skinner. Heating-system for gaseous fuels. (113,945.) Mar. 20.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Blyth and Miles. Means for purifying benzol, etc. 4237. Mar. 11.
 Hoare. Method of manufacturing benzidine sulphate or benzidine base. 4576. Mar. 15.
 Watford. Process for synthetic manufacture of benzene. 4654. Mar. 16.

COMPLETE SPECIFICATION ACCEPTED.

17,398 (1916). Darzens. Process for the separation of cresols. (107,961.) Mar. 20.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

Morris. 4289. 4290. *See XIII.*
 Perkin. Manufacture of indanthrene. 4585. Mar. 15.
 Perkin. Manufacture of violanthrene (or indanthrene dark blue). 4586. Mar. 15.

COMPLETE SPECIFICATION ACCEPTED.

3287 (1917). British Dyes, Ltd., Turner, and Dean. Manufacture of red azo dyestuffs. (113,825.) Mar. 20.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Bastian. 4206. *See XI.*
 Boving and Co., and Hellström. Manufacture of paper pulp. 4277. Mar. 11.
 Cochrane. Treatment of fabrics to render them invisible. 4181. Mar. 9.
 Fleming. Method of treating paper, etc. 4023. Mar. 7.
 Henshilwood and Ward. Treatment of fibrous substances. 3898. Mar. 6.
 Jardine and Nelson. Apparatus for preparing bamboo, etc., for pulp extraction. 4151. 4152. Mar. 9.
 Kelsey. Process for treating sud or magna obtained in scouring or washing wool, hides, flax, jute, etc. 4516. Mar. 14.
 Meyer. Manufacture of textile materials. 4542. Mar. 14. (U.S., Apr. 7, 1917.)
 Robbins. Material for covering wings of aircraft. 4646. Mar. 15.
 Severn, Thomson, and Twycross. 4029. *See XXII.*

COMPLETE SPECIFICATIONS ACCEPTED.

9963 (1916). Fennell, Lane, and Garbutt. Manufacture of paper-makers' pulp. (113,624.) Mar. 13.
 3873 (1917). Volpato. Process of treating straw in the preparation of textile fibres. (113,853.) Mar. 20.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Poulson. Sizing textile fabrics, etc. 3806 and 4055. Mar. 5 and 8.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Brownson, Jones, and Partington. Production of ammonium nitrate. 3792. Mar. 4.
 Calvert. Production of ammonia. 4351. Mar. 12.
 Davis. Production of potash. 3994. Mar. 7.
 Dutt and Dutt. Process for manufacture and production of alumina. 3767. Mar. 4.
 Knapp and Taylor. Production of nitrogen compounds. 4451. Mar. 13.
 Knapp and Taylor. Process of producing ammonia and ammonium compounds. 4455. Mar. 13.
 Mirza. Zinc-oxide furnaces or kilns. 4272. Mar. 11.
 Morris. Manufacture of acetate of lead, etc. 4291. Mar. 12.
 Parkes and Pearson. Fixation of nitrogen of the atmosphere. 4623. Mar. 15.
 Reid. Process of producing carbide. 4445. Mar. 13.
 Reid. Apparatus for making carbide. 4446. Mar. 13.
 Reid. Process for making carbide. 4447. Mar. 13.
 Rideal and Taylor. Purification of hydrogen. 4532. Mar. 14.
 Slocum. Preparation of crude materials for manufacture of calcium carbide. 4448. Mar. 13.
 Slocum. Process for preparation of crude materials for manufacture of metal carbides. 4449. Mar. 13.
 Slocum. Preparation of crude material for manufacture of carbide. 4450. Mar. 13.

Slocum. Process for fixation of nitrogen. 4451. Mar. 13.

Walker. Purifying hydrogen and removing carbon monoxide. 3733. Mar. 4.

Westcott. Preparation of crude materials for manufacture of calcium carbide. 4457. Mar. 13.

COMPLETE SPECIFICATIONS ACCEPTED.

3113 (1917). Hutchins. Manufacture of carbon for electro-chemical, metallurgical, and other services. (113,812.) Mar. 20.

16,456 (1917). British Thomson-Houston Co. (General Electric Co.). Processes for making silicic acid. (113,769.) Mar. 13.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Harrison. Sifters for treating potters' slip, powdered substances, etc. 3823. Mar. 5.

Levi. Refractory substances. 4201. Mar. 11.

COMPLETE SPECIFICATIONS ACCEPTED.

17,366 (1916). Marlow, and Minton, Hollins, and Co. Ovens or kilns for use in the manufacture of tiles, pottery, and other ware, and for other purposes. (113,794.) Mar. 20.

8400 (1917). Gray (General Electric Co.). Apparatus for drawing cane glass and glass tubing. (113,892.) Mar. 20.

9023 (1917). Snodgrass. Manufacture of artificial abrasives. (113,731.) Mar. 13.

IX.—BUILDING MATERIALS.

APPLICATION.

Müller. Compositions for making slabs, etc., and method of making same. 4551. Mar. 14.

COMPLETE SPECIFICATIONS ACCEPTED.

3080 (1917). Ashenhurst. Porous composition of matter for use in heat insulation and for other purposes. (113,810.) Mar. 20.

5749 (1917). Adlam and Daniels. Brick or block for building or constructional purposes. (113,871.) Mar. 20.

15,400 (1917). Gestetner. Composition such as artificial stone. (113,924.) Mar. 20.

16,674 (1917). Volant. Waterproof material for use in constructional purposes as a substitute for leather, for street paving or the like. (111,485.) Mar. 20.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Alexander, Imbery, and Vint. Hardening and tempering steel, etc. 3825. Mar. 5.

Angel. Treatment and reduction of refractory sulphide, etc., ores. 4676. Mar. 16.

Bingham. Apparatus for heating air blast for iron and steel furnaces. 4385. Mar. 13.

Bingham, and Huntington, Heberlein, and Co. Rabbie-arms for mechanical roasting furnaces. 4427. Mar. 13.

Gayley. Sintering ores. 4545. Mar. 14. (U.S., Mar. 30, 1917.)

Harvey, and Morgan Crucible Co. Crucible melting-furnaces. 4682. Mar. 16.

Industrie-en-Mijnbouw-Maatschappij Titan. Smelting titaniferous iron material. 4633. Mar. 15. (Holland, Mar. 15, 1917.)

Jones. Depositing metal by electric arc. 4101. Mar. 8.

Tetley. Metal-melting pots. 4056. Mar. 8.

Vautin. Recovery of metals from slags. 4681. Mar. 16.

Weir. Manufacture of malleable iron castings. 4239. Mar. 11.

COMPLETE SPECIFICATIONS ACCEPTED.

2391 (1917). Keller. Manufacture of steel. (113,635.) Mar. 13.

3113 (1917). Hutchins. *See* VII.

3414 (1917). Beckett. Refining of metals. (113,834.) Mar. 20.

3422 (1917). Insull. Method of and apparatus for welding or sintering tungsten ingots and the like. (113,835.) Mar. 20.

3423 (1917). Insull. Compressed tungsten powder and the like, and method and apparatus for producing the same. (113,836.) Mar. 20.

11,032 (1917). Sugimoto. Gas burners for blast-furnace stoves. (113,740.) Mar. 13.

13,496 (1917). British Thomson-Houston Co. (General Electric Co.). Manufacture of composite bi-metallic articles. (113,758.) Mar. 13.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Antonoff. Electric batteries. 3856. Mar. 5.

Bastian. Electric heating elements and resistances. 4025. Mar. 7.

Bastian. Electrically-heated clothing, etc. 4026. Mar. 7.

Baur and Treadwell. Electric cells or batteries. 4689. Mar. 16.

Baxter. Electric cells and batteries. 3840. Mar. 5.

Bingham, and Huntington, Heberlein, and Co. 3842. *See* 1.

Brown and Morton. Electrolytic cell. 4085. Mar. 8.

Exley and Leitner. Electric accumulators. 4529. Mar. 14.

Exley and Leitner. Manufacture of electric accumulators. 4530. Mar. 14.

Gow. Mounting of electrodes of electric furnaces. 4527. Mar. 14.

Hamer. Conversion of basic or heat-energy contained in energy-carrying fluids into electrical energy. 3829. 3830. Mar. 5.

Howard. Control of electric furnaces. 4428. Mar. 13.

Hoyle and Wrightam. Holders for electrodes of electric furnaces. 4834. Mar. 12.

Illemaun and Montgomerie. 3901. *See* XIII.

Jones. 4101. *See* X.

Pearson. Electric accumulators. 3920. Mar. 6.

Poole. Arc-controlled mechanism for electric arc furnaces. 4153. Mar. 9.

Richardson. Electron discharge devices. 4628. Mar. 15.

Turner and Walker. Mechanism for regulating electrodes of electric furnaces. 3883. Mar. 6.

COMPLETE SPECIFICATIONS ACCEPTED.

3113 (1917). Hutchins. *See* VII.

3318 (1917). Brown, Boveri, and Co., and Gray. Control and regulation of electric furnaces. (113,827.) Mar. 20.

3426 (1917). Insull. Electric furnaces. (113,839.) Mar. 20.

9014 (1917). Bibby. Electric transformers, especially suitable for use in connection with electric furnaces. (113,899.) Mar. 20.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Blundell, Spence, and Co., and Mell. 3801. *See* XIII.

Douglas. Detergent soaps, and making same. 4160. Mar. 9.

Lockwood and Samuel. Treatment of fatty acids or their metallic salts and oils, and manufacture of oxidised products therefrom. 4523. Mar. 14.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Benueche. Paint. 4158. Mar. 13.

Blundell, Spence, and Co., and Mell. Substitute for linseed and other drying oils for use in paints, putty, varnishes, etc. 3801. Mar. 5.

Illemann and Montgomerie. Paint. 3900. Mar. 6.

Illemann and Montgomerie. Non-conducting material. 3901. Mar. 6.

Lockwood and Samuel. 4523. *See* XII.

Mirza. 4272. *See* VII.

Morris. Manufacture of lakes. 4289. Mar. 12.

Morris. Manufacture of chrome yellows. 4290. Mar. 12.

Prior and Warren. Compositions for lacquering, etc. 4274. Mar. 11.

Self. Process for treatment of *Phytelephas* palm, etc., seeds for manufacture of plastic compositions. 4227. Mar. 11.

Self. Composition for use in manufacture of plastic materials. 4629. Mar. 15.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATION.

Broomfield. Manufacture of a rubber compound. 3783. Mar. 4.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Abrahamsen. Tanno-casein compound, and process for manufacture of same. 4347. Mar. 12. (Norway, Mar. 12, 1917.)

Kelsey. 4516. *See* V.

Melbourne and Tilsdon. Apparatus for treatment of hides, etc. 4015. Mar. 7.

COMPLETE SPECIFICATION ACCEPTED.

Conduct catalysis. IV. False equilibria. W. D. Bancroft. J. Phys. Chem., 1918, 22, 22—43.

If a catalysed reversible reaction is brought to a standstill as a result of the poisoning of the catalyst by one or other of the products of the reaction, an apparent or false equilibrium is reached. Various recorded observations are discussed in terms of this mode of explanation. (See also J. Chem. Soc., April, 1918.)—H. M. P.

PATENTS.

Separating air or gases from liquids ; Process and apparatus for —. Rasmussen und Ernst Ges. m. b. H., Chemnitz, Saxony. Eng. Pat. 104,183, Feb. 15, 1917. (Appl. No. 2290 of 1917.) Under Int. Conv., Feb. 16, 1916.

THE apparatus consists of an upright receptacle into which the liquid to be treated enters under pressure through a pipe terminating in a nozzle directed upwards. Air separates from the liquid and collects in the upper space of the receptacle, whence it is led through a narrow opening into another smaller receptacle, and thence escapes into the atmosphere. Any liquid carried over by the air is collected in the second receptacle. The process can be repeated as often as necessary by using two or more receptacles connected together. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 1437 of 1880, 17,158 of 1887, 20,468 of 1900, 6011 of 1906, and 18,165 of 1914.)—J. H. P.

Evaporating plant ; Apparatus for producing and maintaining a variable determined level of liquid in —. E. Barbet et Fils et Cie., Paris. Eng. Pat. 105,543, Jan. 23, 1917. (Appl. No. 1156 of 1917.) Under Int. Conv., Apr. 10, 1916.

THE liquid in the evaporator is balanced by a column of liquid contained in an outer vertical tube which communicates with the evaporator and is provided with overflow cocks at different levels.—W. H. C.

Evaporating liquids ; Apparatus for —. F. Hart, Easton, Pa. U.S. Pat. 1,251,689, Jan. 29, 1918. Date of appl., Nov. 15, 1917.

A NUMBER of elongated tubular evaporators are arranged horizontally in cascade series. The apparatus is provided at the top with liquid inlet and vapour escape openings, and connecting pipes are arranged between the evaporators to maintain a body of liquid in each with a vapour space above the liquid. The liquid is supplied at the upper end and the concentrated liquid withdrawn at the lower end of the series. Means for heating the evaporators are provided.—J. H. P.

Evaporator. [Dryer.] R. W. King and H. G. Miller. The Dalles, Oreg. U.S. Pat. 1,251,696, Jan. 22, 1918. Date of appl., Apr. 11, 1917.

THE apparatus comprises a drying chamber with means for causing a circulation of air through it, and a bleaching chamber or conduit having seals at its inlet and outlet. A conveyor travels through the drying and bleaching chambers, and means are provided for dipping the conveyor through the sealing reservoirs. The material to be dried rests on the conveyor, and is carried through the drying chamber in a circuitous path.—J. H. P.

Drying material in bulk ; Apparatus for —. A. Hofmann, Zürich, Switzerland. Eng. Pat. 109,267, Aug. 29, 1917. (Appl. No. 12,380 of 1917.) Under Int. Conv., Aug. 23, 1916.

THE apparatus consists of a drying chamber above which is a heating chamber. The heating gases,

after passing through tubes for heating the air used for drying, are introduced into a flue extending along and to the whole height of the drying chamber, into which they may be admitted at any place required by means of a series of valves arranged at different heights, the heating gases being mixed with the air inside the drying chamber.—J. H. P.

Fractional distillation. W. G. Adam, London. Eng. Pat. 112,966, Dec. 30, 1916. (Appl. No. 18,671 of 1916.)

THREE or more stills, each provided with a suitable fractionating column, are arranged at different levels, but not superposed, so that the liquid to be distilled may flow through them in succession. The stills are provided with baffles so that the liquid takes a tortuous course, and they are heated to successively higher temperatures by coils through which the heating medium passes in an opposite direction to that taken by the liquid being distilled.—W. H. C.

Brick towers, chambers, acid storage tanks, and the like ; Construction of —. W. A. Coxon, Mitcham. Eng. Pat. 113,015, Mar. 1, 1917. (Appl. No. 2999 of 1917.)

AN inner brick wall or core is faced continuously on both sides with acid-resisting tiles, related together and kept in place by grooved tie bricks built into the wall at intervals. The whole is cemented together with acid-resisting cement.—W. H. C.

Steam ; Generation of —. Feed water heating, and heating of liquids generally. P. St. G. Kirke, London. Eng. Pat. 113,314, Feb. 15, 1917. (Appl. No. 2258 of 1917.)

IN the generation of steam by means of coal gas, producer gas, and the like, the gaseous fuel is mixed with a primary supply of air insufficient to permit back-firing, and as this mixture issues from the primary mixing chamber an additional supply of air to complete that required for combustion is added to and mixed with it. The mixture passes to a combustion chamber through a secondary mixing chamber where the mixing is completed and the velocity of flow increased above that in the primary mixing chamber and combustion chamber. The combustion of the mixture is completed in contact with an incandescent body of refractory material, as in surface combustion. The gaseous fuel is supplied through a nozzle into the primary mixing chamber, and the combustion chamber may be inside or outside the apparatus in which the steam is generated. The cross-section of the secondary mixing chamber may be uniform or increase from inlet to outlet or from outlet to inlet either gradually or abruptly. The air used may be preheated by the waste gases from the combustion chamber.—J. H. P.

Centrifugal separators and methods of discharging same. W. J. Gee, London. Eng. Pat. 113,326 Feb. 21, 1917. (Appl. No. 2579 of 1917.)

IN order to discharge material from a centrifugal separator having a non-perforated drum, such as is described in Eng. Pats. 4155 of 1907 and 9365 of 1915 (this J., 1908, 227 ; 1916, 1206), in such a manner that the various grades remain separated from one another and are thrown into corresponding receptacles, transverse perforated rings are provided which prevent the grades being mixed when the drum is lifted off but allow a free flow of liquid between them. The receptacle into which the solids are thrown is sub-divided into tiers corresponding to the position of the grades so that the

latter are collected separately. Each tier may be provided with a separate scraper and delivery point.—J. H. P.

Extractor; Centrifugal —. G. W. Lewis, Grinnell, Iowa. U.S. Pat. 1,253,987, Jan. 15, 1918. Date of appl., June 11, 1917.

THE perforated container of the centrifugal machine is supported at its upper central point so that it can be tilted. It is provided with a level to indicate when it is accurately balanced in a horizontal position. When so balanced the rotating device is moved into gear and started.

—W. H. C.

Furnace bricks: Treatment of —. A. McD. Duckham, Ashted, England. U.S. Pat. 1,252,415, Jan. 8, 1918. Date of appl., Dec. 5, 1913.

THE bricks are coated or impregnated with a combustible substance (such as paper) impregnated with a material which liberates oxygen when heated and thus provides a space for the expansion of the brick.—A. B. S.

Refrigerating machine; Centrifugal —. V. J. Goetz, Philadelphia, Pa. U.S. Pat. 1,253,026, Jan. 8, 1918. Date of appl., June 10, 1915.

THE gaseous portion of the refrigerating medium is aspirated from a low-pressure chamber into a high-pressure chamber wherein it liquefies and whence it is returned to the expansion chamber. The aspirator is operated by centrifugal force on the compressing medium. The bearings of the centrifugal device are lubricated with the compressing medium.—W. H. C.

Deflocculating solid materials and agents therefor. E. G. Acheson, Assignor to Acheson Corporation, New York. U.S. Pat. 1,253,556, Jan. 15, 1918. Date of appl., Oct. 29, 1917.

AMORPHOUS solid materials are treated with an ammoniacal extract of the product obtained by roasting starchy materials at a temperature just below that at which carbonisation takes place.

—W. H. C.

[Fluid] meter. C. C. Thomas, Baltimore, Md. U.S. Pat. 1,254,374, Jan. 22, 1918. Date of appl., June 27, 1916.

FLUID flowing in a pipe is heated by an electrical heater to which energy is supplied at a constant rate. An electrical resistance thermometer is arranged with its two elements on opposite sides of the heater, so as to measure the temperature difference, which is registered by suitable recording mechanism. The temperature difference is a measure of the rate of flow of the fluid.—W. F. F.

Compressing an elastic fluid; Method of —. H. A. Humphrey, London, Assignor to Humphrey Gas Pump Co. U.S. Pat. 1,254,693, Jan. 29, 1918. Date of appl., June 1, 1909. Renewed June 19, 1917.

SEE Eng. Pat. 12,565 of 1908; this J., 1909, 784.

Emulsifying apparatus. H. H. Schou, Assignor to Flakes A. S., Copenhagen. U.S. Pat. 1,254,734, Jan. 29, 1918. Date of appl., July 12, 1916.

SEE Eng. Pat. 17,306 of 1915; this J., 1916, 1052.

Diffusers for use in diffusing gases in liquids. Eng. Pat. 113,371. See XIXb.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Toluol recovery and standards for gas quality. R. S. McBride. J. Ind. Eng. Chem., 1917, 10, 111—114.

THE gas standards for undertakings in the United States with annual makes above 500 million cub. ft. are tabulated. The legal standards vary largely. In some cities none are prescribed, in some there is a calorific power standard, in some a lighting power standard, while in others the dual standard is in operation. The lighting power standard is sometimes as high as 23 candle power. When carburetted water-gas is made, about 10% of the gas oil used can be recovered as light oil, and of this $\frac{1}{2}$ can be obtained as pure toluene. Coal gas from horizontal retorts will yield about $\frac{1}{2}$ to $\frac{1}{3}$ gallon of light oil per 1000 cub. ft., and of this about 10—12% can be recovered as toluene. For each $\frac{1}{10}$ gallon of light oil recovered there is a fall in the gross calorific value of 10—14 B.Th.U. per cub. ft. and $2\frac{1}{2}$ —3 candles decrease of illuminating power. This could be avoided more or less completely by re-carburetting with the benzene or solvent naphtha fraction, but a full enrichment is probably undesirable in the national interest. Examples of the effects of stripping the different types of town gas supplied are given. The suspension or abolition of illuminating standards is advocated to facilitate toluol production and on general grounds. When the lighting power standard is above 18 candles, a reduction might be made to 12—14 candles in a transition stage for, say, one year, so as to prevent consumers' appliances from becoming suddenly unusable. For coal gas plants a calorific power standard of 550—570 B.Th.U. per cub. ft. is recommended.

—H. J. H.

Toluol production: Intensive —. J. Proposed improvements in the absorbing and stripping process. F. E. Lichtenhafer. Met. and Chem. Eng., 1918, 18, 111—152.

THE three principal sources of toluene in America are coke-oven gas, town gas, and cracked petroleum products. Of these town gas is considered the one most readily available, and washing for toluol is advocated. Washing by tar is recommended in preference to the oil washing process. Simplicity of plant and operation are the features emphasised. A tar washing arrangement is proposed. Tar is condensed, dehydrated by centrifugal machines, and then allowed to descend a tower scrubber of the cap and seal bubbling type through which the gas ascends. The tar enriched with toluene is then put through a steam stripping still with appropriate heat exchange arrangements, whereby light and carbolic oils are removed, and the product is a "dehydrated" tar suitable for road making. The gas is thus washed with its own tar in countercurrent without circula-

tion. As an alternative to the steam still a direct fired pot still is proposed, consisting of a horizontal cylindrical boiler, along which the tar is caused to flow in a zig-zag path by means of baffles. Live steam is introduced in the last three chambers to complete the stripping.—H. J. H.

Benzol: A simple method of manufacturing crude ——. W. Greaves. *Coke-Oven Managers' Assoc.*, Feb. 23, 1918. *Gas J.*, 1918, 141, 398—399.

BENZOL is extracted from coal gas by the usual method of scrubbing, and the benzolised oil is pumped under pressure through a cast-iron coil heated to 145° C. by hot furnace gases. The hot oil is then sprayed into a small still or dephlegmator, the interior of which is at atmospheric pressure. The benzol and water vapour pass away to a condenser and separator, whilst the debenzolised oil flows to the oil coolers to be again used for benzol absorption. It is easy to produce the ordinary 65% crude benzol, and the advantages of this method are stated as follows:—Small capital cost, no house required, little ground space, and less expensive parts required than in the ordinary method; inferior fuel may be used for heating the coil; simplicity of working, the fire, pump, and thermometer alone requiring attention; durability and quickness of erection.—J. E. C.

Oil industry: A new British ——. (I.) E. H. C. Craig. (II.) F. M. Perkin. (III.) A. G. V. Berry and A. E. Dunstan. *Inst. Petroleum Tech.*, Feb. 19, 1918. [Advance proof.]

(I.) BRITISH sources from which oil may be obtained by distillation are oil-shales, coal, cannel coal and torbanites, blackband ironstones, lignite, and peat. Of these the only source at present being utilised is oil-shale, which is mined and retorted only in Scotland. From this source not more than about 300,000 tons of oil fuel for the Navy can be obtained in a year's working. Of the other sources of liquid fuel, coal yields too little and is too valuable to be utilised on a large scale, lignites are not yet available for development on a sufficient scale, and peat has proved troublesome and expensive to treat owing to the difficulty of eliminating water. The remaining possible sources of oil, viz., cannel coals, torbanites, and blackband ironstones, are closely associated, and are, in many cases, easily obtainable. Most cannels contain a very large amount of "jetonised" spores, which are believed to yield on distillation waxes and resinous compounds. Torbanites, though externally similar, are essentially different from true cannels. They consist of a coal matrix in which are embedded yellow or brown globules of "kerogen." These globules vary greatly in size, shape, and number, and contain a considerable proportion of inorganic matter in close, and apparently chemical, combination with hydrocarbons of organic origin. They undergo a degeneration of which four stages have been distinguished, and the quality of oil (paraffins and olefines) yielded on distillation varies according to the stage of this degenerative process, the most degenerated types yielding quantities of heavy paraffin waxes, while the fresher material yields a greater proportion of light oils. Every gradation between a typical torbanite and a typical cannel exists. Owing to the high ash percentage in cannel coals (20 or even 30%, and seldom under 10%), large quantities of cannel have been dumped as useless for fuel purposes, together with impure coaly or canneloid bands ("Jacks, Gees, Rattlers, Batts," etc.) which could not under any pretext be sold as coal. All these deposits, however, contain kerogen globules and uncarbonised vegetable matter from which oil can be obtained

on distillation. Blackband ironstones contain iron oxide or hydroxide in very intimate association with carbonaceous material which is kerogenous or only slightly carbonised, and is thus capable of yielding oil by distillation. Hitherto, blackband ironstones have been prepared for the blast furnace by being burnt in the open with a quantity of admixed coal, but it has recently been demonstrated by Hollingworth (Eng. Pat. 18,103 of 1914; this J., 1915, 1255) that the oil contents of these ores can be extracted by distillation, the nitrogen content being obtained as ammonium sulphate, and sufficient non-condensable gas produced to supply the heat required for the retorts. The residue, designated "carbousiron," consists of ironstone with intimately associated fixed carbon. It is now proposed to exploit the various deposits in this country of cannels and bastard cannels, torbanites, and blackband ironstones, by low-temperature carbonisation, for the extraction of oil and all possible by-products. It is considered probable that over the whole country the cannels and torbanitic cannels will yield from 33 to 35 galls. of crude oil per ton. The petrol obtainable will probably vary from 1 to 10, and the oil fuel from 60 to 70% of the crude oil. The average yield of ammonium sulphate may be estimated at 30 to 40 lb. per ton. The amount of solid paraffin wax recoverable will probably be less than is obtained from the Scotch oil-shales, but an advantage which cannels have over the oil-shales is that the retort residues from the poorer grades can be worked up into very fair briquettes, while those from the better grades can be utilised in producers, to give not only all the power-gas required, but the full yield of ammonium sulphate. Only large central works, situated with due regard to supplies and facilities for transport, and capable of dealing with at least 1000 to 2000 tons of cannel per day are projected. At least six such retorting and refining works could be established without any difficulty. The goal aimed at is some 400,000 tons of oil fuel per annum, and some 6 or 7 million gallons of petrol, besides intermediate oils.

(II.) The urgent importance at the present juncture of increasing the country's oil-fuel supplies is emphasised, and the question of the relative advantages of high- and low-temperature carbonisation of coal, etc., discussed. High-temperature treatment is necessary for the production of benzol and other aromatic compounds required for the manufacture of high explosives, but the yield of oil is low. Low-temperature carbonisation on the other hand gives a maximum yield of oil, but aromatic compounds are absent. By passing steam through coal as it is being carbonised at a high temperature in vertical retorts, considerably larger yields of gas and tar are obtained, but the tar contains very little benzol and toluol.

(III.) The methods employed in the testing of cannel coals for yield of oil are described, and the nature and refining of the crude oil discussed. The results of several tests are given. Crude cannel oil has the following properties:—Sp. gr., 0.887 to 1.000; sulphur, 0.4 to 1.1%; setting point, 5° to 30° C.; water, after partial separation, 1 to 4%; calorific value of dry oil, 9.550 to 9.655 cal. per grm. (17,190 to 17,379 B.Th.U. per lb.). The following fractions are obtainable by refining:—Benzene, approximately 3%, sp. gr. about 0.740 to 0.750, with a final boiling point of 170° C. Intermediate oil, approximately 12%, sp. gr. about 0.800, flash point about 80° F.; such an oil would be an excellent light fuel for tractors, etc. Navy fuel oil, approximately 50 to 60%, sp. gr. about 0.870, flash point over 170° F., and setting point below 25° F. Paraffin scale, variable, averaging approximately 3 to 4%. Pitch, hard or soft as required, more bituminous in character than coal-tar pitch, and at the worst, mixed with oil, would produce a works fuel.—T. ST.

Improvements in apparatus for the manufacture of concentrated ammonia liquor. Greaves, *See* VII.

PATENTS.

Coke-ovens. D. Campbell and C. Goodyear, Vancouver, B.C., Canada. Eng. Pat. 112,967, Jan. 12, 1917. (Appl. No. 629 of 1917.)

A SPACE is formed beneath the floor of a coking chamber, communicating on the one hand by means of parallel interspaces with the chamber and, on the other, by means of a floor sloping to an aperture covered by a grating, with means for inducing draught. The space is filled with a permeable mass of finely-divided material, such as gravel or rock, and trap channels may be provided to remove condensed liquid products.—J. E. C.

Coke-oven. L. Wilputte, New Rochelle, N.Y. U.S. Pat. 1,253,760, Jan. 15, 1918. Date of appl., May 2, 1917.

REGENERATORS are placed below each half of the coking chamber and parallel thereto. Air and gas are supplied to the regenerators alternately, and each regenerator is provided with a separate waste gas outlet. One set of regenerators is connected by conduits to a common flue, the alternate set being similarly connected to a second main flue.

—J. E. C.

Coke-oven. J. E. Hubbell, Philadelphia, Pa., Assignor to L. Wilputte, New Rochelle, N.Y. U.S. Pat. 1,254,007, Jan. 15, 1918. Date of appl., June 14, 1917.

THE regenerators are situated under each half of the heating wall of the coke-oven and parallel to the same. Two passages communicating longitudinally with the base of the regenerators are provided, with means for supplying fluid to be preheated to one, and for withdrawing waste gases from the other.—J. E. C.

Gas producers. T. R. Wollaston, Manchester. Eng. Pat. 113,025, Mar. 19, 1917. (Appl. No. 3964 of 1917.)

A GAS producer is divided at or about the position of the grate into two or four distinct sectors, each provided with one or more pairs of crusher rolls moveable independently. The crushed clinker from these rolls falls into a water-lute and is propelled by water jets to a desirable part of the plant for removal.—J. E. C.

Gases: Generation of — [by electrolysis] for use in internal combustion engines. G. C. Coloma, Kelso, Scotland. Eng. Pat. 113,048, May 21, 1917. (Appl. No. 7271 of 1917.)

A LIQUID, *e.g.*, water, is decomposed by the action of an electric current passing between two electrodes, one in each section of a divided receptacle. The gases from one section escape to the atmosphere, whilst those from the other section are conducted to the combustion chamber of the engine.—J. E. C.

Gas producers. J. Stewart, Glasgow. Eng. Pat. 113,182, Apr. 10, 1917. (Appl. No. 1982 of 1917.)

IN a suction or pressure gas producer, the upper part consists of an outer casing, 5, with a refractory lining, 1, resting on an annular plate, 6, and provided with the usual inlet and outlet openings. The conical base, 8, may be built up of a number of plates attached to the ring, 9, which forms one member of a ball bearing and also carries worm teeth so that it may be slowly rotated by the worm, 11, operated by hand or power. The base, 8, is also provided with two or more grates, 14, with inclined sides and having slots so arranged that air or a mixture of air and steam passing

through them tends to pass over the inner surface of the base, 8. One or more water-cooled pokers, 19, having projecting arms, 20, are supplied with water by the pipe, 21. The lower part, 15, of the casing is conical and dips into the water in the trough, 17. Air mixed with steam produced in the

chamber, *b*, enters the producer at the lower edge of the base piece, 8, and through the grates, 14. In a modification an annular opening is also provided between the ring, 9, and annular plate, 6, forming an additional communication between the chamber, *b*, and the producer chamber.—W. F. F.

Gas producers, furnaces, and the like: Mechanical feeders for —. E. W. Harvey, London, and E. N. Wright, Wolverhampton. Eng. Pat. 113,203, May 10, 1917. (Appl. No. 6626 of 1917.)

IN an apparatus suitable for feeding fuel mechanically to circular gas producers, furnaces, and the like, the fuel contained in a hopper is distributed by an oscillating circular valve of known form into an open-ended oscillating and revolving shoot which delivers it into the furnace. The distributing shoot is oblong in horizontal cross-section, and is supported near its upper end by horizontal trunnions journaled in the wall of a hollow cylinder surmounting the mouth of the furnace. The cylinder is provided with annular water seals at the top, where it engages with the supporting framework of the distributing valve, and at the bottom, where it engages with the top of the furnace. The hollow cylinder is rotated slowly and the trunnions carrying the distributing shoot are oscillated. The fuel is thus distributed by the shoot during its oscillation over a diameter of the furnace, and the plane of oscillation of the shoot is gradually rotated so as to cover the whole circumference of the furnace.—W. F. F.

Gas producer. H. J. Ambruson, Assignor to Morgan Construction Co., Worcester, Mass. U.S. Pat. 1,252,612, Jan. 8, 1918. Date of appl., Jan. 25, 1915.

A GAS producer comprises a fuel shell, and blast-distributing means consisting of hollow radial arms in communication with an annular blast-distributing member. The shell and blast-distributing means rotate in unison.—J. E. C.

Bunsen burners. Fletcher, Russell and Co., T. W. Fletcher, and W. Banks, Warrington, Eng. Pat. 113,069, Aug. 18, 1917. (Appl. No. 11,879 of 1917.)

A DEVICE for regulating the gas supply and adjusting the area of the nipple orifice of a Bunsen burner comprises a casing, *a*, a nipple, *b*, a sliding

non-rotating stem, *d*, a nut, *c*, a pyramidal portion, *p*, adapted to co-act with an orifice of corresponding shape, and supporting wings, *o*.—J. E. C.

Gas burners for furnaces. Fletcher, Russell and Co., Ltd., T. W. Fletcher, and J. H. Singleton, Warrington, Eng. Pat. 113,239, Sept. 21, 1917. (Appl. No. 13,583 of 1917.)

THE mixture tube of a gas burner for furnaces is provided with two or more fan-shaped nozzles projecting laterally, arranged in line or "staggered," and spaced close together along the tube. —W. F. F.

Hydrocarbon oils and spirits; Refining — J. Nelson, Glasgow, Eng. Pat. 113,131, Feb. 6, 1917. (Appl. No. 1861 of 1917.)

HYDROCARBON oils and spirits obtained by cracking kerosene, solar oil, and other heavy hydrocarbons, are decolorised, deodorised, and the tendency to develop gumminess removed, by treating them with an unsaturated fatty oil such as linseed, cotton, rape, or other oil, with or without phosphoric acid. For example, volatile hydrocarbons boiling below 150° C., obtained by cracking kerosene, are mixed with 20% of raw linseed oil, and the mixture is distilled. The residue in the still may be used for treating a further quantity of spirit. In a modification, a heated chamber containing pumice soaked in linseed oil, or a heated tower down which linseed oil flows, is interposed between the still and condenser. A second purifying chamber containing pumice and phosphoric acid may also be interposed between the linseed oil chamber and the condenser. Further purification may be effected by storing the treated hydrocarbon over water containing 0.5% of caustic soda, or by passing the vapours over soda-lime heated to a temperature above the condensing point of the vapours. Hydrocarbons containing constituents boiling up to 250° C. may also be treated by this process, with or without the use of a dephlegmator to separate the lighter fractions of the cracked oil.—W. F. F.

Light oils; Art of recovering — [from gas]. R. B. Parker, Assignor to Senet-Solvay Co., Solvay, N.Y. U.S. Pat. 1,252,181, Jan. 8, 1918. Date of appl., Mar. 6, 1916.

LIGHT oil vapours are absorbed from gas by a solvent oil. The volatile components of this oil are distilled off, the more volatile compounds separated from the heavier distillates including the olefines, and the latter purified with sulphuric acid and re-distilled.—J. E. C.

Oil; Apparatus for dehydrating — R. R. Pollak, San Francisco, Cal. U.S. Pat. 1,251,271, Jan. 22, 1918. Date of appl., July 6, 1914.

FROM a perforated partition in a vessel, oil drips on to a horizontal series of perforated plates and thence flows on to coils of steam pipes. The supply of steam can be controlled by hand and by thermostatic means. Below the pipes is a vertical series of inclined, perforated drip plates, below which are other coils of steam pipes. The vessel is also provided with a cooling chamber and a conduit containing means for heating the air therein, and a condenser leads from above the cooling chamber to a centrifugal blower of regulated speed, whilst another conduit containing two condensers with receiving chambers leads from an upper portion of the vessel to the blower.—L. A. C.

Gas-producer plants; Generator for — G. H. Allen, North Fremantle, W. Australia. U.S. Pat. 1,251,107, Jan. 22, 1918. Date of appl., July 27, 1915.

SEE Eng. Pat. 10,881 of 1915; this J., 1916, 1005.

Process and apparatus for calcining and roasting certain ores [by means of exhaust gases from gas engines]. Eng. Pat. 105,915. See X.

Process for the manufacture of drying-oils [from kerosene]. U.S. Pat. 1,251,866. See XIII.

A new British oil industry. Craig and others. See IIA.

PATENTS.

Charcoal; Production of decolorising — R. von Ostrejko, Cracow, Austria. Eng. Pat. 106,089, Apr. 3, 1917. (Appl. No. 1813 of 1917.) Under Int. Conv., May 4, 1916.

POWDERED charcoal is heated in a retort, and steam, superheated by the waste gases of the furnace, is admitted at the top of the retort. The gases thereby generated pass from the bottom of the retort to the heating furnace in which they are burnt with a regulated supply of air. After treatment with the steam a portion of the charcoal is removed from the retort proper and further heated in boxes in the hearth of the heating furnace, whilst a corresponding quantity of fresh charcoal is supplied to the retort.—J. E. C.

Coal; Distillation of — G. E. Heyl, London. Eng. Pat. 113,012, Feb. 22, 1917. (Appl. No. 2630 of 1917.)

TO obtain a greater yield of oil from coal, it is soaked in about 10% of its mass of mineral or coal-tar oil, and after distillation up to about 200° C., an additional 10% is added and the distillation continued up to a temperature of about 400° C.—J. E. C.

Bituminous coal; Destructive distillation of — F. C. Blythe, Southsea, Hants. Eng. Pat. 113,079, Oct. 29, 1917. (Appl. No. 15,728 of 1917.)

THE distillation is carried out at a comparatively low temperature, under pressure, on coal to which heavy hydrocarbon oil has been added, whereby the production of hydrocarbon oils is favoured at the expense of permanent gas (see Eng. Pat. 19,750 of 1914, this J., 1915, 1016). When the suitable temperature has been attained the pressure is released and the distillation completed at atmospheric pressure or under a vacuum.

—H. J. H.

Anti-cathode. E. W. Kelly, Philadelphia, Pa. U.S. Pat. 1,251,700, Jan. 29, 1918. Date of appl., Sept. 30, 1916.

AN iron-nickel alloy, having a coefficient of linear expansion approximately equal to that of tungsten, is used as the anti-cathode, and a refractory member of tungsten is welded directly to the mass.—B. N.

IV.—COLOURING MATTERS AND DYES.

Dyes of the 1,2-phthaloylacridone ["anthraquinone-acridone"] series. F. Ullmann and P. Dootson. Ber., 1918, 51, 9—24.

New acridone dyes have been obtained by condensing 1-aminoanthraquinone with the methyl ester of a substituted *o*-chlorobenzoic acid, hydrolysing the ester so formed, and treating the free *o*-anthraquinonylamino benzoic acid with concentrated sulphuric acid. The parent 1,2-phthaloylacridone (always designated "anthraquinone-2,1-acridone" by Ullmann) can also be obtained most readily, from methyl *o*-chlorobenzoate, by this method. 6-Amino-1,2-phthaloylacridone

crystallises in bluish-violet tablets, and dyes cotton in a hydrosulphite vat the same shade, whereas the unsubstituted phthaloylacridone gives reddish-violet shades. 6-Methoxy-1,2-phthaloylacridone forms small, violet leaflets, and gives a vat of the same colour. 7-Methoxy-1,2-phthaloylacridone separates as a wine-red mass of needles, and dyes cotton red. 1,2-Phthaloyl-

6,7-benzoacridone forms dark violet needles, gives a green vat, and dyes cotton bluish-violet, whereas the isomeric 5,6-benzo-compound, "Indanthrene Red B.N. extra" of Ger. Pat. 237,236 (this J., 1911, 1153), dyes red shades. (See also J. Chem. Soc., April, 1918.)—J. C. W.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Aeroplanic dopes. Esselen, jun. See XIII.

PATENTS.

Flax fibre: Process and apparatus for treating [decorticating]—. A. Meiro, Moscow. Eng. Pat. 113,285, Jan. 26, 1916. (Appl. No. 1224 of 1916.)

FLAX fibre obtained from dry flax straw or from wet steeped or dew-retted flax is broken by passing between smooth horizontal rollers. Separate bunches of the fibre are then folded in half and the bundles tied tightly with string, pushed into horizontal tubes attached to the vertical shaft of the apparatus and secured on hooks therein. The apparatus consists of a vertical, jacketed cylinder with a central shaft carrying brackets to which the horizontal tubes already mentioned are attached, those tubes near the centre being larger in diameter than those further away. The tubes are provided with small turbines at one end, and the hooks to which the flax is attached are fixed on the vanes and axes of the turbines. When the tubes are filled with flax the vessel is charged with water and crude linseed oil, or with water alone, and the shaft is caused to rotate. The heated liquid passes through the tubes parallel with the flax fibre and causes the turbines together with the attached bundles of flax to rotate within the tubes. The refuse is thus detached, and is separated from the discharged liquid by sieves. Subsequently the cleaned fibre is drained and then dried by circulating air through the tubes.—J. F. B.

Paper-making and the like; Automatic steam control mechanism for the drying cylinders used in—. C. Stickle, Indianapolis, Ind., U.S.A. Eng. Pat. 113,240, Sept. 25, 1917. (Appl. No. 13,803 of 1917.)

THE sheet of paper to be dried passes in zig-zag form over a series of heated cylinders, portions of two cylinders, 11, being shown. A spindle, 32,

mounted in a fixed bearing sleeve, 30, carries the two arms, 33, 36, of a bell-crank lever. The arm, 33, is provided with a roller which rests on the sheet of paper, 12, as it passes through the machine, and the arm, 36, passes through an elongated opening in the spindle, 43, of a valve, 19, in the pipe, 18. Stops, 37, on an extension of the arm, 36, are provided to limit the movement of the arm. Pressure water is supplied to the pipe, 18, and operates a reducing valve in the main which supplies steam to the drying cylinders. When the

sheet, 12, is too damp it sags downward and the arm, 33, follows it, tending to close the valve, 19. The pressure water which holds the steam reducing valve in reducing position is thus cut off, and the reducing valve allowed to open to admit more steam to the drying cylinders. When the paper is relatively dry, it contracts, the arm, 33, moves upward, and the valve, 19, opens, admitting pressure water to close the reducing valve, thus diminishing the supply of steam to the drying cylinders.—W. F. F.

Paper and fabrics [embossing paper]; Process and apparatus for covering — with metal foil. F. Tscheike, Fürth, Bavaria. Eng. Pat. 113,297, Jan. 16, 1917. (Appl. No. 813 of 1917.)

PAPER is coated with a resinous adhesive which only acquires its maximum adhesiveness at a high temperature or under the action of volatile solvents; it is then passed over a stretching cylinder on to a heated support and the foil is applied to the sticky surface of the paper and attached thereto by a pressure roller or polished steel press-plate, preferably cooled with water. Sheets of foil may be applied by hand with intermittent feeding of the paper, using a horizontal heated support, or rolls of foil may be applied mechanically by continuous feeding against the paper stretched on a heated cylinder and pressed by means of a water-cooled pressure roll also in contact with the cylinder. Embossing paper is made by covering the metal side of the coated paper with a second coating of adhesive of greater adhesive strength than the first, so that, when applied to a foundation by the pressure of a heated die, the foil adheres to the foundation and is released from the paper-backing in the same operation.—J. P. B.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Ammonia; Oxidation of — to oxides of nitrogen. W. G. Adam. Chem. Trade J., 1918, 62, 181—182.

WILTON and Davis studied this reaction in 1908 at the gas works at Beckton, both on the laboratory and works scale, but until 1917 the relative prices of nitre and ammonia prevented its commercial application for the manufacture of nitric acid. Since Aug. 1917, several sulphuric acid plants on the works have been supplied with nitrous gases produced by oxidation of ammonia instead of by the use of nitre pots. Early experiments showed that the catalyst is best used in the form of a wad of platinum gauze, $\frac{1}{2}$ in. thick. The reaction is started by inserting a plug carrying an electrically heated spiral close up to the gauze.

The ammonia air mixture, which is normally 1:10, is temporarily enriched until the reaction is in active progress, when the heat of the reaction suffices. The time of contact of the mixture with the catalyst was estimated at 0.0046 sec. at 600° C. The oxidation of ammonia must be complete as any remaining unconverted will react with the oxides of nitrogen formed producing free nitrogen. A minimum time of contact is thus necessary, and it must be in one stage so that oxides of nitrogen will not be in contact with unchanged ammonia. Four layers of platinum gauze in the wad sufficed and no advantage was secured by the use of more. The yields in the works were checked by absorption of the oxides of nitrogen in sulphuric acid of 144° T. (sp.gr. 1.72) and came up to those obtained in small scale plant.—H. J. H.

Nitrogen problem in Switzerland. P. A. Guye. Schweiz. Chem.-Zeit., 1918, 2, 3—6.

OF the processes of nitrogen fixation discussed in the recent United States report (this J., 1917, 1081—1085), the arc process is considered most suitable for Swiss conditions as water power is plentiful and the process requires practically no imported raw material. The annual national requirements are estimated at 5000 tons of nitric acid and 5000 tons of nitrate fertilisers, which together would require about 20,000 kilowatts or 27,000 H.P., whilst the available water power in the country is about 2 million H.P. The necessity for transporting nitric acid could probably be obviated by collecting the oxides of nitrogen from the arc gases, not by absorption in water but in the form of liquid nitrogen peroxide. This boils at 26° C. and can be transported in sheet iron tanks and converted directly into 96% nitric acid by means of water and air at the centres where the acid is required. The arc process could probably be made to supply the Swiss demand for ammonia, estimated at about 800 tons NH_3 , for recent laboratory experiments show that gaseous nitric acid can be reduced to ammonia, to the extent of 70%, by means of hydrogen and finely divided nickel, at temperatures between 250° and 300° C. and at atmospheric pressure.—J. H. L.

Ammonia liquor; Improvements in apparatus for the manufacture of concentrated —. W. Greaves. Coke-Oven Managers' Assoc., Feb. 23, 1918. Gas J., 1918, 141, 398.

SINCE the outbreak of the war there has been a great demand for concentrated ammonia liquor containing a minimum of 25% NH_3 and a maximum of 0.5% H_2S , as against a pre-war standard of about 16 to 18% NH_3 . The apparatus required for the former consists of an ammonia still and its accompanying lime still, large enough to deal with the various ammonia liquors sent to them, and to allow the added lime to combine with sufficient hydrogen sulphide to satisfy the final test, at the same time removing as much carbon dioxide and cyanide as possible. In addition a still is required to expel a portion of the hydrogen sulphide, and some means of condensing the excess of steam in the ammoniacal vapours. The author describes a method of converting a sulphate of ammonia plant into a concentrating plant. The change necessitated the provision, in addition to three ammonia stills already installed, of an ammonia still, lime still, and two reflux coolers, together with pumps, piping, etc. The incoming gas liquor passes through a reflux condenser, cooling the vapours from the still, and becoming itself heated to about 71° C. It then passes to one of the old stills where it meets a little live steam on its way down the still, the aim being to drive off a maximum of hydrogen sulphide and carbon dioxide, with a minimum of ammonia. The original liquor

contains 0.75% NH_3 and 0.23% H_2S and the partly desulphurised liquor contains 0.69% NH_3 and 0.15% H_2S , so that 35% of the latter is removed at the expense of 8% of the ammonia. This figure can be improved but only by increasing the ammonia content of the waste gases passing to a special scrubber. As the quantity of ammonia passing thence to the ammonia still is limited by the amount of hydrogen sulphide which can be extracted in the lime still, it is a mistake to work with strong gas liquor when making concentrated liquor. At the plant referred to, water was added in the scrubbers to bring the ammonia content down to 0.7%. The waste gases from the desulphuriser consist of hydrogen sulphide, hydrocyanic acid, and carbon dioxide, along with their ammonia compounds. A small steam jet in the outlet pipe assists in overcoming troubles due to deposits of ammonium carbonate. The partly desulphurised liquor passes on to the lime still, and it has been found advantageous to allow the entry from the lime still into the ammonia still to be made higher than in the case of ammonium sulphate manufacture, to allow more time for the lime to act on the ammonium carbonate; in addition more lime is required. The ammonia and steam from this still pass through the first reflux cooler to extract some of the water vapour and thence through a second reflux cooler and final condenser, the finished product showing an average of 28 to 29% NH_3 and 0.20% H_2S . The temperatures at the control points of the plant are:—Gas liquor entering first reflux condenser, 15° C.; liquor entering desulphuriser, 71° C.; vapours leaving desulphuriser, 77° C.

—J. E. C.

Potash and other constituents: Extraction of— from sea water bittern. J. H. Hildebrand. J. Ind. Eng. Chem., 1918, 10, 96—105.

AROUND San Francisco Bay 110,000 tons of salt is produced annually by the solar evaporation of sea water. The salt is accompanied by 3000 tons of potassium chloride and still larger quantities of magnesium salts which are now wasted. The possibilities of recovering this potash from the bitterns remaining after the removal of salt are discussed in the light of van't Hoff's studies of oceanic salt deposits. It appeared that if the evaporation, crystallisation, and filtration of the bittern were carried out at a high temperature, magnesium chloride and sulphate and salt could be separated almost free from potassium salts, while the potassium chloride would become concentrated in the mother liquor. On cooling the mother liquor, carnallite ($\text{KCl} \cdot \text{Mg}(\text{Cl})_2 \cdot 6\text{H}_2\text{O}$) crystallises, and by extraction with a limited quantity of water, magnesium chloride passes into solution and potassium chloride is left. In practice it is recommended to concentrate the mother liquor from solar evaporation pans until its boiling point is 120° C. and its sp. gr. 1.35 at the boiling point. The solid should be separated from the hot liquid by settling in a steam jacketed tank and by centrifuging the precipitate hot. The mother liquor is cooled to allow carnallite to crystallise. From the latter magnesium chloride is extracted, using water equal to about one-half the weight of the carnallite, and potassium chloride crystals are left. The methods of recovering the sulphate and chloride of magnesium and bromine are discussed. Attention is drawn to a similar process proposed by Nishimura (J. Chem. Ind. Tokyo, 1917, 20, 587; this J., 1917, 1046.)

—H. J. H.

Cement mill dust: Direct heat treatment of— to increase its water-soluble content. A. R. Merz. J. Ind. Eng. Chem., 1918, 10, 106—109.

THE character of the flue dust from cement kilns using the Cottrell precipitator differs according

to the fuel used. In one works using oil-fired kilns, 92% of the potash in the dust was soluble in water. From two coal-fired plants the proportions of water-soluble potash were only 60% (A) and 41% (B). A further proportion of the potash which could be extracted by 5% hydrochloric acid is classed as "slowly soluble." This has been usually regarded as due to re-combination of potash with the ash of the coal used as fuel. Nestell and Anderson (this J., 1917, 926) state that on extraction for 10 hours with boiling water, it becomes soluble. Porter (Portland Cement Assoc., Chicago, Sep., 1917) claims that the addition of salt to the charge prevents re-combination of the potash. Ross (this J., 1917, 642) has shown that digestion with lime water under pressure is effective. Potash can be set free from silicates by heating them with lime, and as the latter is present in flue dust, simple ignition should have some effect. On heating the dusts with an equal quantity of calcium carbonate for 40 mins. at 1000° C. in a Lawrence Smith crucible, the water-soluble portion of A (see above) rose from 60% to 90%, while in the case of B it fell from 41% to 30%, the re-combination having gone still further. Dust A was grey, while B was black and contained 9.26% of carbon and also sulphide. On igniting the dusts alone under oxidising conditions in a muffle at temperatures varying from 600° to 1100° C. the potash became almost completely soluble in both cases—98% in A and 93% in B. No advantage was attained by prolonging the heating above 20 minutes.—H. J. H.

Potash: Effect of coal ash on liberation and nature of cement kiln—. N. S. Potter, jun., and R. D. Cheesman. J. Ind. Eng. Chem., 1918, 10, 109—111.

THE authors dispute the view that the insoluble and slowly soluble portion of the potash in flue dust from coal-fired cement kilns is due solely to re-combination with the coal ash. Some may be due to unchanged coal ash rich in potash. The average K_2O content of coal ash used in a certain cement works is about 5% and as the coal consumption in cement kilns varies from 80 lb. to 250 lb. per barrel of cement, this ash alone can furnish from 0.1 to 1.25 lb. of K_2O per barrel. The ash is so finely divided that little is retained by the charge especially when the dry process is used. Samples taken at every 10 ft. of the length of a kiln showed that some potash was being absorbed by the charge in its progress and probably from the coal ash. The bulk of the ash probably passes forward unchanged, with its potash insoluble, to be collected by the precipitator. Laboratory experiments show that simple heating does not render the potash of the coal ash soluble.—H. J. H.

PATENTS.

Acetic acid: Manufacture of—. H. Dreyfus, Basle, Switzerland. Eng. Pat. 105,065, Mar. 6, 1917. (Appl. No. 3324 of 1917.) Under Int. Conv., Mar. 6, 1916.

IN the manufacture of acetic acid by oxidation of acetaldehyde with air or oxygen by aid of a catalyst, improved yields are obtained by maintaining the reaction chamber at a temperature above the boiling point of acetic acid, preferably between 130° and 400° C. The mixture of air or oxygen and acetaldehyde is heated on its way to the reaction chamber in chambers through which pass the pipes carrying the hot acetic acid vapour from the reaction chamber.—B. V. S.

Potassium chloride from natural silicates, rocks, minerals, residues or wastes containing potash: Manufacture of—. E. A. Ashcroft, London. Eng. Pat. 113,211, June 5, 1917. (Appl. No. 8010 of 1917.)

By heating a mixture of felspar and sodium chloride

in suitable proportions to a temperature between 800° and 1200° C., in the absence of air or moisture, the greater part of the potash is converted into chloride, its place in the felspar being taken by sodium. The product, after cooling, may be extracted with water and the potassium chloride separated from the excess sodium chloride by crystallisation. It is preferable, however, to use a percolation method, the fused chloride passing downwards over the felspar and being drawn off from the bottom of the container. The greater part of the potassium passes off in the first portions, the extraction of the potassium is more complete for the same excess of sodium chloride, and the chloride left in the residue is chiefly the sodium salt, which may be dissolved out and used for the treatment of more felspar without separating the small portion of potassium chloride it contains. In this method the addition of a little magnesium chloride is an advantage as it increases the fluidity of the fixed chloride. The process is applicable to other substances containing insoluble potassium salts and other chlorides than sodium chloride may be used. (See also *ibid.* J., 1918, 51 A.)—B. V. S.

Potassium chloride: Process for purifying —. A. B. Cox, Cherry Valley, N.Y., Assignor to General Reduction Gas and By-products Co., New York. U.S. Pat. 1,252,784, Jan. 8, 1918. Date of appl., Apr. 17, 1915.

SODIUM monocarbonate, bicarbonate, and sulphate, borax, and other impurities which will form insoluble calcium compounds, are precipitated from the crude potassium chloride solution by the addition of calcium chloride, and the potassium chloride is recovered from the filtrate by fractional crystallisation.—A. B. S.

Potassium salts [from greensand]: Process for extracting —. F. Tschimer, Newark, N.J. U.S. Pats. (A) 1,251,150 and (B) 1,251,151, Jan. 22, 1918. Dates of appl., Apr. 18 and May 3, 1916.

(A) THE product obtained by roasting a mixture of greensand (glauconite) and grey, calcareous marl is ground in water, treated with chlorine gas, and dried. The material is then roasted until the mass becomes yellow, and leached with water to extract the potassium chloride produced. (B) A mixture of greensand marl, 100, "lime sand," 50, and calcium chloride, 30 parts, is heated to 800 — 820° C. to convert the potassium of the greensand into chloride.—W. E. F. P.

Potash products: Process of recovering high-grade —. J. R. MacMillan, Assignor to Niagara Alkali Co., Niagara Falls, N.Y. U.S. Pat. 1,254,521, Jan. 22, 1918. Date of appl., Oct. 9, 1916.

LIQUID containing potassium and sodium as carbonates and other soluble salts is evaporated to about 40° B., and any salts crystallising out are removed. The solution is cooled and any normal sodium carbonate which separates is removed; the solution is then treated with carbon dioxide at 20°–30° C., the precipitated sodium bicarbonate filtered off, and the filtrate cooled to or below 0° C. The potassium bicarbonate which separates out is filtered off. The mother liquor is evaporated to 40° B. and the process repeated.—L. A. C.

Ferrous alkali silicates: Method of treating — [for the production of potassium chloride]. Method of treating potash-bearing silicates. W. Glaeser, Fullerton, Pa., Assignor to Potash Extraction Corporation, New York. U.S. Pats. (A) 1,251,676 and (B) 1,251,677, Jan. 29, 1918. Date of appl., Mar. 9, 1917.

(A) A MIXTURE of the silicate and calcium chloride, with or without a "porous material," all in finely divided condition, is heated sufficiently to expel

moisture and combined water without oxidising the ferrous iron present, *e.g.*, at a temperature not exceeding 270° C., and then to about 800° C. in a non-oxidising atmosphere. (B) A mixture of the finely divided silicate and calcium chloride in equal proportions, with or without about 5% of a reducing oxide of iron, is dehydrated at about 500° F. (260° C.) and then heated to above 900° C. in a non-oxidising atmosphere.—W. E. F. P.

Aluminium hydrate [hydroxide]: Method of precipitating —. R. S. Sherwin, East St. Louis, Ill., Assignor to Aluminium Co. of America, Pittsburgh, Pa. U.S. Pat. 1,251,296, Dec. 25, 1917. Date of appl., July 16, 1913.

PORTIONS of a solution of an alkali aluminate containing precipitated aluminium hydroxide are withdrawn from the bottom of a tall vessel containing the solution and re-introduced at the top in the form of a fine spray through a column of air. Cooling is thereby effected and the precipitate is intimately mixed with the liquid.

—L. A. C.

Alums: Process for preparing — from clay or other similar natural compounds of alumina. L. L. Jackson, Assignor to O. C. Horney, New York. U.S. Pat. 1,251,229, Jan. 22, 1918. Date of appl., Jan. 11, 1917.

UNCALCINED clay and nitre-cake are heated to a temperature between 150° C. and that required to decompose nitre-cake. Silica in an almost entirely insoluble condition is formed and is separated from the soluble products, sodium sulphate and soda alum.—L. A. C.

Silicates of magnesium: Process for decomposing —. L. L. Jackson, Assignor to O. C. Horney, New York. U.S. Pat. 1,251,230, Jan. 22, 1918. Date of appl., Jan. 19, 1917.

SILICATES of magnesium resistant to acid (*e.g.*, soapstone) are heated with a hydrate of an alkali metal (*e.g.*, sodium hydroxide). The alkali silicate formed is separated, the insoluble residue treated with dilute acid, and the magnesium salt recovered by washing.—L. A. C.

Chlorine and sulphate of sodium: Process of producing — by catalysis. H. B. Kipper, New York. U.S. Pat. 1,255,020, Jan. 29, 1918. Date of appl., July 5, 1916.

IN a continuous process for producing chlorine and sodium sulphate from sodium chloride, a mixture of the latter with a catalyst, *e.g.*, ferric oxide, is subjected to the action of sulphur dioxide and oxygen, at about 600° C., in a horizontal, cylindrical, rotary chamber.—W. E. F. P.

Zirconia: Manufacture of a new compound of zirconium and its application in the production of pure —. The Imperial Trust for the Encouragement of Scientific and Industrial Research, London, and R. T. Glazebrook, W. Rosenhain, and E. H. Rodd, Teddington. Eng. Pat. 112,973, Jan. 29, 1917. (Appl. No. 1440 of 1917.)

A MIXTURE of crude zirconia, fluorspar, and concentrated sulphuric acid is heated until the acid begins to fume. The mass is agitated with boiling water to extract the soluble sulphates and the solution is decanted from any insoluble calcium sulphate. Hydrochloric acid of sp. gr. 1.15 is then added and is followed by concentrated ammonia until a white precipitate of basic zirconium sulphate begins to form. The precipitation is allowed to continue without the further addition of alkali. The basic sulphate may also be obtained by dissolving zirconium hydroxide in dilute hydrochloric acid, concentrating the solution until crystals form, re-crystallising these

from hydrochloric acid, then re-dissolving them and adding sulphuric acid or a sulphate. Substantially pure zirconia is made by igniting the basic sulphate. Zirconium hydroxide may be prepared by suspending the basic sulphate in water, adding strong ammonia, and washing until free from sulphate. Zirconium oxychloride is made by dissolving zirconium hydroxide in dilute hydrochloric acid and concentrating until crystals form abundantly.—A. B. S.

Sulphuric acid; Method of concentrating—. J. V. Skoglund, New York. Eng. Pat. 113,551, May 14, 1917. (Appl. No. 6841 of 1917.)

VIII.—GLASS; CERAMICS.

Lime-alkali glasses; Classification of—according to the Tschuschner formula. J. Koerner. Sprechsaal. 1915, 48, 333. J. Soc. Glass Techn., 1917, 1, 140—141.

THE Tschuschner formula for good glasses of the lime-alkali type: $z = 3(x^2 + 1)$, where x and z represent the molecular proportions of alkalis and silica respectively per 1 mol. of lime, holds good for pure lime-soda glasses, but for lime-potash glasses the formula $z = 4(x^2 + 1)$ is more satisfactory. When, as is usually the case, the glass contains both soda and potash, a modified formula is necessary, viz., $z = \left(3 + \frac{x_k}{x}\right)(x^2 + 1)$ for glasses in which the preponderating alkali is soda, and $z = \left(4 - \frac{x_{Na}}{x}\right)(x^2 + 1)$, where potash preponderates; in these formulae x_k and x_{Na} represent the molecules of potash and soda respectively. Eighty different lime-alkali glasses were tested by the method suggested by Mylius (viz., treatment with water at 18° C. for seven days, and then with water at 80° C. for 3 hours, and estimating the dissolved alkali volumetrically). It was found that the most resistant glasses all fell within relatively narrow limits of composition, and notwithstanding some slight variations it is concluded that the results confirm from the practical point of view the value of the modified Tschuschner formula in determining the ratio of alkalis to silica most suitable for the production of a good glass.

"Glass-gall" in soda-lime glasses. H. Knoblauch. Sprechsaal. 1915, 48, 185. J. Soc. Glass Techn., 1917, 1, 116—117.

"GLASS-GALL" is due to the presence of un-

decomposed salt-cake and appears only in glasses made from batches containing this substance. Salt-cake batches usually contain carbon (ground coal, coke, or anthracite), which acts as a reducing agent and aids the decomposition of the salt-cake. Some salt-cake remains undecomposed if insufficient carbon be used, but excess of carbon does not necessarily prevent the appearance of glass-gall. In presence of excess of carbon the gall may appear brownish-red and begin to foam badly, and the whole body of glass may be "seedy" and difficult to fine. It is best to mix the carbon with the salt-cake (after being slightly damped) before its addition to the other batch materials, and it is essential to have a high furnace temperature in melting, as otherwise some of the carbon may be oxidised before the salt-cake melts and so may not exert its proper reducing action. The presence of gall-stones throughout the body of metal generally indicates that the furnace temperature is too low and the metal too viscous to allow the stones to rise to the surface. Gall-stones sometimes appear in the metal after this has been perfectly clear, probably owing to separation of dissolved undecomposed salt-cake when the temperature falls somewhat during "standing off" or as the metal approaches the working end of a tank. Glasses rich in soda dissolve salt-cake more readily than those of high lime or silica content. Gall-stones in cullet cannot be removed by re-melting with an additional quantity of carbon, as this would produce discoloured glass.

PATENTS.

Compartment kiln. R. H. McElroy. Assignor to International Clay Machinery Co., Dayton, Ohio. U.S. Pat. 1,254,421, Jan. 22, 1918. Date of appl., June 20, 1917.

A GAS-FIRED continuous kiln is provided with water-smoking openings and flues with bag walls at each side of each chamber, with burner-openings behind these bag walls and individual air flues for each burner-opening, the air-flues being beneath and communicating with the perforated soles of the chambers.—A. B. S.

Mortar for firebricks. U.S. Pat. 1,252,785. See IX.

IX.—BUILDING MATERIALS.

Direct heat treatment of cement-mill dust to increase its water-soluble potash content. Merz. See VII.

Effect of coal ash on the liberation and nature of cement mill potash. Potter, jun., and Cheesman. See VII.

PATENTS.

Cement and lime kilns or the like; Charging apparatus for—. A. Steiger and W. W. Steiger, Zürich, Switzerland. Eng. Pat. 109,264, Aug. 24, 1917. (Appl. No. 12,187 of 1917.) Under Int. Conv., Aug. 26, 1916.

AN automatic charging device for kilns consists of a vertical pipe fitted with a perforated cone-valve at its lower end, so as to cause the larger lumps in the charge to roll towards the centre of the furnace and the smaller pieces to the circumference, thereby creating a uniform resistance to the passage of gases through the furnace. The cone is adjustable horizontally and/or vertically. An electric contact device effects the stoppage of the supply of material as soon as the latter reaches a predetermined height in the pipe. A suction

pipe for the waste gases is provided in order to facilitate the passage of air through the middle of the material in the furnace.—A. B. S.

Mortar for firebricks. A. B. Cox, Cherry Valley, N.Y., Assignor to General Reduction Gas and By-Products Co., New York. U.S. Pat. 1,252,785, Jan. 8, 1918. Date of appl., Apr. 14, 1917.

A MORTAR for firebricks which will vitrify when heated to a comparatively low temperature, is composed of 75 parts of shale, 25 parts of ground firebrick, 30 parts of sodium silicate, and 75 parts of asbestos.—A. B. S.

Concrete resistant to moisture; Method of rendering —. A. E. Horn, New York. U.S. Pat. 1,255,116, Jan. 29, 1918. Date of appl., Oct. 20, 1917.

CONCRETE is made waterproof by adding to it a substance (such as a solution of ammonium resinate) which accelerates the formation of colloidal substances in the cement.—A. B. S.

Wood; Process for preserving—W. A. Cecil, Evansville, Ind. U.S. Pat. 1,253,667, Jan. 15, 1918. Date of appl., Sept. 25, 1916.

THE wood is placed in a retort, which is then filled with the preservative liquid, the latter being kept under pressure and in circulation by passing it to and from another (open) vessel. The pressure of the liquid in the retort is gradually increased and is maintained at a maximum until the wood is properly impregnated. The use of an open supply vessel enables free air to be eliminated from the retort.—A. B. S.

Wood and other porous materials; Process and apparatus for impregnating—with preservative fluid. H. S. Loud, New York. U.S. Pat. 1,253,814, Jan. 15, 1918. Date of appl., Feb. 9, 1916.

THE pieces of wood or other articles are placed in three retorts connected together by valve-controlled pipes and are impregnated with the preservative fluid in the following cycle: (1) The articles are drenched with the fluid under atmospheric or reduced pressure without being submerged; (2) the air pressure is gradually increased and the drenching continued, still without submergence; and (3) the articles are submerged and the liquid applied under hydraulic pressure. The liquid is withdrawn from one retort at the completion of the cycle and transferred to the second retort to drench the wood therein, the air displaced from the second retort being used to increase the pressure in the second stage of the process in the third retort. The various stages of the cycle occur in each of the retorts in turn.—A. B. S.

Wood, etc.; Impregnation of—M. Rüping, Berlin, Assignor to Hülsberg und Co., Charlottenburg, Germany. U.S. Pat. 1,255,310, Feb. 5, 1918. Date of appl., Dec. 4, 1913. Renewed Dec. 7, 1917.

SEE Fr. Pat. 166,263 of 1913; this J., 1914, 618.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Gold; Application of charcoal to the precipitation of —from its solution in cyanide. H. R. Edmonds, Bull. 161, Inst. Min. and Met., Feb. 1918. [Advance copy.] 25 pages.

At the Yuanni Gold Mines (Western Australia), zinc dust was used for precipitating gold from cyanide solution. At first a mixture of oxide

and roasted sulphide ore was treated, but subsequently, when the supply of the former had become exhausted and roasted ore only was treated, difficulties arose in precipitating the gold. Investigations into the suitability of charcoal as a precipitant having proved satisfactory, it was substituted for zinc dust in August 1916. The charcoal, freshly burnt, quenched, and washed, is finely ground in a ball mill while wet. Precipitation is effected by filtration through cakes of charcoal powder in Moore-Edmonds vacuum extractors, which were previously employed in zinc dust precipitation. The operation is conducted in at least two, preferably three, stages, each of the three extractors containing 300 lb. of charcoal. When sufficiently charged with gold, the vacuum is released, the cake emulsified, and the pulp passed through a clean-up press, the cake from which is burnt and the ash melted down. The plant, which handles 350–400 tons of solution per day, gives a better recovery at a smaller cost than when zinc-dust precipitation was used.

—W. R. S.

Copper ores; Some experiments in heap-leaching —. G. D. Van Arsdale. Eng. and Min. J., 1918, 105, 225–233.

HEAP-LEACHING of copper ores is not at present practised on a commercial scale in the U.S.A., but the low grade ore deposits in the South-West are being tested by this process. At Tyrone, N.M., an old ore dump of 20,000 tons, assaying 2.71% Cu, is being leached with acid ferrous sulphate liquor; the extraction was 20% in 10 months. At Bisbee, Ariz., a large amount of low-grade ore, which had to be removed from the workings, was made into a heap containing 9500 tons, the ore assaying 1.30% Cu. So far, a recovery of 26.9% has been realised in 7 months. From the small preliminary tests, the extraction by leaching is estimated to be 40% for the first year, 20% for the second, and 15% for the third. It is now planned to treat a heap of about 40,000 tons at Tyrone. The ores experimented upon are sulphides.

—W. R. S.

Spelter; Recovery of —and treatment of [zinc] retort residues. E. M. Johnson. Met. and Chem. Eng., 1918, 18, 135–139.

THE classification of spelter is controlled by the iron and lead content, which increases very considerably between the first and last draws of the furnace. Care is necessary to secure a representative sample of a large parcel. Where the sample is taken by drilling plates, iron may be introduced from the bit. This is avoided when the sample is taken by granulating a small ladleful from each draw. Retort residues may carry considerable quantities of copper, precious metals, and lead, and may repay examination and treatment. The cheapest method of dressing for concentrating is simple screening. Jigging tests are reported but the results are not very decisive. Magnetic separation effected a high separation of iron. A certain degree of concentration can be effected by burning the carbonaceous matter out of the residue by a simple heap roasting, which is beneficial to subsequent smelting. A reported test of a smelting operation on retort and other smelter residues mixed with a suitable proportion of fresh ores and flux, showed a financial loss under conditions which were rather unfavourable. The author considers the metallurgical results promising for operations on a larger scale.—H. J. H.

Stibnite; Blast-furnace smelting of —, with considerations on the metallurgy of antimony. W. R. Schoeller. Bull. 161, Inst. Min. and Met., Feb., 1918. [Advance copy.] 31 pages.

STIBNITE ore containing 50% Sb was smelted in a

circular 36-in. water-jacketed blast furnace having a shaft 10 ft. high. The charge was made up of ore 100, foul slag 156, tap cinder 80, chalk 40, iron 28, and coke 60 lb. The antimony in the slag varied between 0.5 and 1.5%, that in the matte from 2 to 7%, whilst the metal produced assayed Sb 75 and Fe 20%, the balance being chiefly sulphur. The furnace smelted 4.9 tons of ore per 24 hours: the yield of metal was 60%, slag and matte losses 6.5%, the rest being volatilised as dust and fume. The latter, which was not recovered satisfactorily owing to inadequate condensing plant, was of a purple colour and contained 70% of metal. As the antimony was always ferruginous even when the proportion of iron in the charge was reduced much below the theoretical quantity, it was decided to try the effect of smelting without iron. After adjusting the addition of coke to 8–10% of the charge it was found that, instead of a product high in sulphur, practically pure antimony was obtained (e.g., Sb 97.55, Fe 0.42, S 0.41%), whilst no matte was formed, showing that all the sulphur was oxidised and volatilised. The author concludes that the blast is responsible for the conversion of stibnite into metal, by partly oxidising the molten ore to trioxide, which at once reacts with the unaltered sulphide, yielding metal and sulphur dioxide. That this reaction is possible in a gas current has been previously established (this J., 1915, 6; 1914, 169; 1913, 260). The furnace plant and its manipulation are described; the conditions for obtaining the best results are stated to be: less than 10% of coke, low blast pressure, metal content of charge about 10%, height of smelting column 15 ft., continuous discharge and separation of slag and metal in a heated fore-hearth: the condensing system should include a dust chamber, a sufficient number of iron cooling-pipes, a long iron flue, an exhaust fan, and a bag-house or wet-condensing tower. The conclusion is, that the blast furnace is not adapted to high-grade ores but is very suitable for poorer material (25–40% Sb). The French process should be applied to the poorest ores or smelting-residues (less than 25% Sb). Liquefaction is a useful concentrating process for ores containing 45–60% Sb, giving "crude antimony" and residues, which latter are treated by the French or blast furnace process. "Crude antimony" and ores richer than 60% Sb are advantageously treated by "precipitation" smelting in reverberatory furnaces, the matte from which is roasted to recover antimony.—W. R. S.

PATENTS.

Iron-sponge; Production of—A. Sinding-Larsen, Vestre-Aker, Norway. Eng. Pat. 113,351, Mar. 14, 1917. (Appl. No. 3721 of 1917.)

Is the dry reaction process for the production of iron-sponge from iron ore, a horizontal reaction chamber, *a*, is provided with a reciprocating trolley slightly shorter than the chamber, carrying a hearth, *c*. The hearth has side walls projecting

upwards, enclosing a space, *t*, covered by an iron plate, *i*, which carries the ore, and which is spaced at its sides from the side walls. The ore is fed from a hopper, *b*, on to the plate, *i*, when the outlet is not closed by the elevated portion, *f*. Short triangular prisms, *k*, are fixed on the roof of the chamber, with their edges so arranged that the ore is prevented from moving with the plate, *i*, in one direction, but is allowed to move in the other direction. A movement of the ore towards the outlet, *p*, is thus produced. Hydrogen is supplied by the pipes, *h*, to the space, *t*, in which electrical heaters are arranged. The ore is reduced to iron sponge, and the water vapour diffuses downwards and is condensed in the lower part of the chamber, which is cooled by water pipes, *o*. The ascending hydrogen is preheated by the hot vapour. Dry hydrogen is supplied by the pipe, *r*, to complete the reduction of the iron as it passes out by the passage, *p*.—W. F. F.

[*Iron*] *ores; Process of treating*—A. S. Dwight, New York, U.S. Pat. 1,254,316, Jan. 22, 1918. Date of appl., June 17, 1911. Renewed June 2, 1917.

PULVERULENT iron ore containing lower oxides than ferrite is mixed with a pulverised carbonaceous material, and fed in a thin layer on to a moving conveyor. The carbonaceous material is ignited at one point in its travel and air is passed downwards through the mixture. The hot combustion gases oxidise the ore to an extent equivalent to ferrite, and the oxidised particles cohere so as to form thin cakes. The layer of material on the conveyor is of such thickness that the carbon is burnt out, leaving the oxide in cellular form, and the temperature is kept below that of "silicification" of the metal.—W. F. F.

Iron and steel surfaces; Rust-proofing—Process for rust-proofing iron and steel, W. J. Oeschger, Assignor to Parker Rust Proof Co. of America, Detroit, Mich. U.S. Pats. (A) 1,254,263 and (B) 1,251,261, Jan. 22, 1918. Date of appl., Feb. 21, 1917.

(A) IRON oxide is heated and agitated with phosphoric acid and water until a granular mass is obtained; this is placed in excess of water and heated, and the iron articles immersed therein to form a protective coating. Acid metaphosphates of tungsten, molybdenum, or any of the metals of the third, fourth, and fifth groups, in an excess of water, may be used in a similar manner. (B) The iron or steel is subjected to the fumes from heated acid metaphosphates of iron, tungsten, molybdenum, or any of the metals of the third, fourth, and fifth groups.—T. H. B.

Coating of [iron or steel] pipes [with zinc], E. T. Greenfield, Kiamasha, N.Y. U.S. Pat. 1,254,796, Jan. 29, 1918. Date of appl., Nov. 27, 1915.

AN iron or steel pipe is pickled in dilute sulphuric acid, washed, and a flux containing hydrochloric acid applied to the exterior only. It is then dipped in molten zinc, withdrawn, and the molten metal on the interior of the pipe allowed to flow away. In this way the pipe is coated on the exterior only.—T. H. B.

Calcining and roasting certain ores; Process and apparatus for—[by means of exhaust gases from gas engines], L. E. Tissier, Batna, Algeria. Eng. Pat. 105,915, Apr. 18, 1917. (Appl. No. 5463 of 1917.) Under Int. Conv., Apr. 28, 1916.

EXHAUST gases from engines using poor gas are used for calcining zinc, iron, or manganese carbonates, or gypsum, or for roasting metal sulphides.

A furnace is constructed with two concentric walls of refractory bricks, the intermediate space being packed with wood ashes for heat insulation. The floor of the furnace is a perforated plate surmounting the exhaust chamber of the engine, so that the hot gases pass upward through the material. The material is fed in at the top and withdrawn through side openings. If the heat is insufficient for roasting sulphides or calcareous materials, a small quantity of wood charcoal may be added.—W. F. F.

Metal [zinc, aluminium]: Method of and apparatus for reducing — to a finely divided state. Metals Disintegrating Co., Inc., New York, Assignees of E. J. Hall, Passaic, N.J., U.S.A. Eng. Pat. 109,257, Aug. 10, 1917. (Appl. No. 11,522 of 1917.) Under Int. Conv., Aug. 28, 1916.

THE solid metal, *e.g.*, zinc or aluminium, is fed into a crucible heated by gas, and provided with an internal conical baffle below the charging opening to minimise the cooling effect of the charge on the molten metal. The molten metal passes downwards through a central vertical pipe to a nozzle, which is surrounded by an annular nozzle to which steam is supplied to atomise the metal. The metal nozzle is constructed of tungsten or other metal having no affinity for the molten metal. The metal is atomised into a larger vertical conduit having a series of compressed-air jets around its periphery to carry away the atomised metal and cool the nozzle. The atomised metal falls into a container which is connected to an exhaust pump.—W. F. F.

Zinc: Method of and arrangements for extracting — by the electro-thermal process. E. S. Berglund, Trollhättan, Sweden. Eng. Pat. 109,435, July 18, 1917. (Appl. No. 10,379 of 1917.) Under Int. Conv., Sept. 5, 1916.

THE vapours containing zinc are conducted from two or more electric smelting furnaces to a common condenser, so that one or more furnaces may be put out of action, and the delivery of vapours from these furnaces to the condenser cut off by a suitable arrangement in the gas channel, without disturbing the action of the remaining furnace or furnaces. The vapours, in their passage to the condenser, are passed through a vapour-collecting and heating chamber, in which the temperature, before they enter the condenser, is regulated by electrical heating means to the temperature suitable for condensation to molten zinc.—B. N.

Furnace, more especially intended for the treatment of zinc. L. van Gulck, Swansea. Eng. Pat. 113,393, June 23, 1917. (Appl. No. 9053 of 1917.)

IN a reversible gas-heated muffle furnace, particularly applicable for the treatment of zinc, the gas supply in a common conduit may be diverted by a valve into one of the longitudinal passages, 5a, from which it passes through the passage, 6a, to the combustion chamber, 7a. The air supply in a similar common conduit is diverted by a valve into the passage, 10a, from which it passes through the regenerator, 8a, and passage, 9a, to the combustion chamber, 7a. Spaced shelves for the muffles, C, are provided above the combustion chamber so that the hot gases circulate around them. The hot gases then pass over the central wall, 3, over the other set of muffles and through the regenerator, 8b, and passages, 10b, and 20, to the chimney. When the furnace is to be reversed, the air and gas valves are reversed so as to direct the air and gas into passages, 5b and 10b, respectively, and the hot gases then pass through the regenerator, 8a. Sliding shutters, such as 33, are

provided to regulate the supply of gas and/or air, and similar shutters are provided to regulate the opening to the flue passage, 20. A number of double compartments such as described are arranged adjacent to one another in a single

refractory casing; the valve chambers for the air and gas valves are all on one side and the valves are operated simultaneously by interconnected mechanism.—W. F. F.

Zinc: [Electrolytic] method of smelting —. I. Partanen, Te luride, Colo. U.S. Pat. 1,251,531, Jan. 22, 1918. Date of appl., Feb. 2, 1916.

"BLUE POWDER" is treated with chlorine in the presence of moisture, the mixture of zinc chloride and hypochlorite thus produced is fused, and pure zinc is separated from the mixture by electrolysis and withdrawn, whilst the chlorine is again introduced into the furnace into contact with a further supply of "blue powder."—B. N.

Aluminium: Process for soldering —. E. H. Moll et Cie., Paris, Assignees of A. H. Alexandre, Levallois-Perret, France. Eng. Pat. 110,758, Oct. 27, 1917. (Appl. No. 15,682 of 1917.) Under Int. Conv., Oct. 27, 1916.

TIN, 55 parts, and zinc, 45 parts, are fused together, 2.5 parts of stearine added, and the mixture stirred and cast into sticks. The softness of the solder may be modified by varying the proportions of tin and zinc. In a modification, the proportions may be tin 75 parts, zinc 45 parts, fine silver 1.65 parts, yellow brass 1.35 parts, and stearine 2.5 parts. The aluminium parts to be soldered are cleaned, heated by a blow-lamp, and then rubbed with a stick of the solder. The tinned surfaces are pressed together, and then strongly heated and allowed to cool.—W. F. F.

Amalgamators and separators. E. C. R. Marks, London. From The Diver Mineral Separator Co., Calgary, Canada. Eng. Pat. 113,202, May 7, 1917. (Appl. No. 6484 of 1917.)

IN an apparatus for recovering gold, silver, and platinum from sand or other material, the material is fed from a hopper into the upper end of a vertical pipe into which a jet of air, steam, or water is

injected downwards. An air opening is also provided to avoid the formation of a vacuum. The mixture is projected from the bottom of the pipe on to the surface of a quantity of mercury in a cup placed below, and the lighter particles, having a higher velocity, rebound from the surface of the mercury, whilst the heavier particles are retained, the gold and silver being amalgamated, and the platinum sinking to the bottom. To prevent heavy particles of sand from collecting between the mercury and the cup, a ring having outward and inward flanges is fitted into the top of the cup. The lighter particles, also containing metal values, which rebound from the mercury, pass down into a perforated pan, from which they are sifted into another pan. The pans are oscillated slightly at right angles, and a spray of water is directed over the material in them.—W. F. F.

Metal powder: [Electrolytic] process of making —. W. C. Moore, Lakewood, Ohio, Assignor to National Carbon Co., Inc. U.S. Pat. 1,254,056, Jan. 22, 1918. Date of appl., July 29, 1915.

METAL powder is prepared by electrolysing a solution of a salt of the metal, so as to form spongy metal on the cathode; the metal sponge is removed and washed in a colloidal solution to free it from electrolyte, whereby a protective coating is precipitated on the metal particles, and protects them from oxidation. The coated particles are then dried *in vacuo*.—B. N.

Furnace: Electric smelting —. F. T. Snyder, Oak Park, Ill. U.S. Pat. 1,254,079, Jan. 22, 1918. Date of appl., Mar. 1, 1917.

THE roof of the furnace is carried by a removable frame supported by the base, and can thus easily be removed. Columns of ore and combustible material are fed downwards near the "outer circumference," and the charge is then forced laterally into the melting chamber in contact with the roof, and against the inner edge of a charging port, whereby the latter is sealed against the escape of gas.—B. N.

Metallurgical [electric] furnace. W. Buhl, Carnegie, Pa. U.S. Pat. 1,254,308, Jan. 22, 1918. Date of appl., Aug. 20, 1917.

AN electric furnace, with a tilting bowl, has guide-ways arranged to tilt with it. Masts for supporting the electrodes are mounted on the guide-ways to allow horizontal movement relative to the bowl, and the furnace roof is connected with the electrode-supporting masts so that it can be raised from the bowl.—T. H. B.

Ores: Process for the concentration of —. J. T. Terry, jun., Mascot, Tenn. U.S. Pat. 1,254,173, Jan. 22, 1918. Date of appl., Mar. 21, 1917.

COMPLEX sulphide ore containing iron sulphides is crushed, and treated with a solution of lime, an ammoniacal solution, and a frothing agent; the iron sulphides become immune to flotation, and rising bubbles carry away the metallic values.

—T. H. B.

[Alloy.] *Composition of matter*. F. T. Schuller, Minneapolis, Minn. U.S. Pat. 1,254,854, Jan. 29, 1918. Date of appl., Aug. 6, 1917.

AN alloy of Al 96 to 98%, Sn $3\frac{1}{2}$ to $1\frac{11}{16}$ %, and P $\frac{1}{16}$ to $\frac{3}{16}$ %.—T. H. B.

Alloy. H. S. Cooper, Assignor to The Cooper Research Co., Cleveland, Ohio. U.S. Pat. 1,254,987, Jan. 29, 1918. Date of appl., Oct. 15, 1917.

AN alloy of 99–1% of aluminium and 1–99% of beryllium, but preferably not more than 20% of beryllium.

—W. F. F.

Conduits for electric wires. U.S. Pat. 1,254,344. See XI.

XI.—ELECTRO-CHEMISTRY.

Electric cell: A permanganate —. A. W. Warrington. Chem. News, 1917, 117, 97–98.

A DILUTE solution of potassium permanganate (3.16 grms. in 250 c.c.), acidulated with 6 c.c. of sulphuric acid, is used as the depolarising agent in a porous vessel containing a carbon plate, and a strong solution of zinc sulphate (14.55 grms. in 750 c.c.) in the outer compartment containing zinc. The voltage obtained with two such two-fluid cells in series was about 4 volts, and after 3 hours, 3.7 volts, whereas two similar one-fluid cells in series gave about 3 volts after a run of 3 hours. (See also J. Chem. Soc., April, 1918.)—B. N.

PATENTS.

Electrolytic apparatus. J. T. King, Toronto, Canada. U.S. Pat. 1,254,045, Jan. 22, 1918. Date of appl., Apr. 19, 1917.

AN electrolytic vessel, which may be rotated on a suitable support, is provided with electrodes supported by two pairs of clamps, one of each pair being connected to slides actuated by springs. The rotating support is connected to a spindle carried in a bearing, the latter being adjustable vertically in a guide. The electrode circuit is provided with a shunt circuit, normally open, which includes contact plates mounted on the guide. A contact piece is carried by the bearing, and is adapted to engage the contact plates and close the shunt circuit when the support is moved a predetermined distance from the electrode clamps.—B. N.

Furnace: Electric —. F. T. Snyder, Oak Park, Ill. U.S. Pat. 1,254,077, Jan. 22, 1918. Date of appl., Jan. 19, 1914.

THE electric furnace is mounted centrally on the upper end of an arc-shaped arm, which projects through the "pouring floor," whilst the remainder of the arm is concealed beneath the floor. The pouring spout of the furnace is near the centre of the circle of which the arc is a part, and the arm may be moved along the path of the arc to elevate and tilt the furnace, by means of rotating rollers supporting and gearing with the arm. The furnace is thus tilted without moving the spout appreciably, whilst the position of the arm permits unobstructed access to the spout.—B. N.

Conduit for electric wires. D. H. Murphy, Pittsburgh, Pa., Assignor to The American Conduit Manufacturing Co. U.S. Pat. 1,254,344, Jan. 22, 1918. Date of appl., Sept. 19, 1913.

AN iron or steel conduit is provided with an acid-resisting non-corrosive coating on one or more of

its surfaces, which is obtained by electrolytically depositing a thin layer of pure lead, and covering this with a thin layer of pure zinc to fill the minute recesses in the lead, both layers being sufficiently thick to withstand chemical corrosion. A non-corrosive coating is applied over these layers to prevent electrolysis.—B. N.

Electric-furnace electrodes; Water-jacket for —. H. J. Kitchen, Luton. U.S. Pat. 1,254,510, Jan. 22, 1918. Date of appl., Mar. 7, 1917.

SEE Eng. Pat. 101,201 of 1916; this J., 1916, 1023.

Electrolytic apparatus. G. F. Jaubert, Paris. U.S. Pat. 1,255,096, Jan. 29, 1918. Date of appl., July 26, 1917.

Generation of gases [by electrolysis] for use in internal combustion engines. Eng. Pat. 113,048. See IIA.

XII.—FATS; OILS; WAXES.

Rice polishings; Oil from —. F. Garelli Annali Chim. Appl., 1917 8, 109—114.

IN commerce rice polishings are mixed with variable proportions of chaff, and used as a fertiliser or feeding stuff. Prior to the war the product was largely exported from Italy, especially to Switzerland and Germany, where it was sold on the basis of the combined fat and proteins. The best qualities contain from 24 to 26%, and inferior qualities from 15 to 16% of fat and proteins. Owing to its porous character the ground material does not keep well, and the contained fat readily becomes rancid. It yields on the average about 6.5% of oil. Oil expressed from freshly separated material had the following characters:—Sp. gr., 0.918; acid value, 13.8; saponification value, 179.4; Hehner value, 94.3; glycerol, 9.03%; and unsaponifiable matter, 0.7%. The fat extracted with petroleum spirit from another sample melted at 25° to 26° C., had acid value 90; and contained 4.95% of glycerol and 3.2% of unsaponifiable matter. The acidity of the oil varied with the kind of rice, the period of production, and the state of preservation. In order to obtain oils low in acidity and rich in glycerol it is necessary to express the rice polishings as soon as possible after their separation, or, better, to destroy the lipolytic enzymes by heat. The press-cake resembles sesame oil-cake in appearance. A sample contained: moisture, 14.60; nitrogen, 2.73; and fat, 8.68%.—C. A. M.

Soap solutions; Studies of —. II. V. Lenher and G. M. Bishop. J. Phys. Chem., 1918, 22, 68—72.

THE emulsification of various oils by the action of soap solution has been examined. Measured quantities of the oil and N/10 sodium oleate solution were mixed with water to give a total volume of 100 c.c. The mixture was heated to 100° C., violently agitated for 5 mins., and then allowed to stand for 5 mins. If oil separated on standing, the experiment was repeated with more sodium oleate solution and less water. By a process of approximation, the volume of soap solution required to bring about complete emulsification was determined. The volumes of soap solution required for the emulsification of 10, 20, 30, 40, 50, and 60 c.c. of oil respectively, under the

specified conditions, were determined in the case of cotton seed, corn (maize), olive, linseed, peanut (arachis), rape seed, castor, sesame, and sperm oils. The results show that the quantity of soap solution increases much less rapidly than the quantity of oil when the volume of this is less than about 40 c.c. For larger quantities of oil, the rate of increase in the required amount of soap solution is much greater.—H. M. D.

Seeds of Echinocystis oreana [; Oil from —.] M. R. Daughters. J. Ind. Eng. Chem., 1918, 10, 126—127.

The wild cucumber, *Echinocystis oreana*, is a common plant in waste places from British Columbia to California. Specimens of the seeds collected in three successive years had the following composition—Crude fat, 30.11 to 35.45; proteins, 20.64 to 23.71; starch, 9.20 to 12.05; crude fibre, 20.01 to 22.07; moisture, 3.90 to 4.51; and ash, 2.6 to 2.89%. Oils expressed in the cold and extracted with petroleum spirit had the following characters:—

	Sp. gr. at 25° C.	Refract. index at 25° C.	Solidif. point. °C.	Iodine value.	Saponif. value.
Extracted oil	0.9267	1.4722	+5 to -8	116.5	190.4
Expressed oil	0.9166	1.4701	+5 to -8	117.0	189.1

Freshly-ground seeds yielded an olive-green oil with a taste resembling that of olive oil. On exposure to light the colour faded in a few days to golden yellow. Hydrogenated with a nickel catalyst at 220°—240° C. it yielded a yellowish-white fat which melted at 29°—36° C. and had an iodine value of 76.6. Feeding experiments with mice showed that the original oil and the hydrogenated fat were non-poisonous.—C. A. M.

PATENTS.

Hard [hydrogenated] fats; Apparatus for manufacturing —. K. Kimura, Kobe, Japan. Eng. Pat. 113,232, Aug. 31, 1917. (Appl. No. 12,512 of 1917.)

AN unsaturated fatty oil, a catalyst such as nickel carbonate, and hydrogen gas are agitated in a vertical cylinder enclosed in a steam jacket. A central vertical shaft carries an agitator comprising a framework, star-shaped in horizontal cross-section, each radial portion being covered by metallic netting of nickel, platinum, iron, or silver. The central shaft also carries a supporting spider for the spindles of similar planet agitators which thus revolve around the central agitator. Each planet spindle carries a spur-wheel which engages with an internally toothed ring on the wall of the container. The central agitator causes a centrifugal movement of the liquid outwards, and the rotation of the planet agitators causes an intimate mixing and subdivision. Suitable inlets and outlets are provided for the oil and hydrogen.

—W. F. F.

[*Nickel catalyst suspended in oil.*] *Product of hydrogenation.* C. Ellis, Montclair, N.J. Re-issue 14,429, Jan. 29, 1918, of U.S. Pat. 1,226,620, May 15, 1917. Date of appl., Dec. 18, 1917.

XIV.—INDIA-RUBBER ; GUTTA-PERCHA.

Rubber ; Vulcanisation of — by selenium. C. R. Boggs. J. Ind. Eng. Chem., 1918, 10, 117—118.

A STANDARD 30% Para rubber compound was partially vulcanised when heated for 2 hours at 150° C. with black selenium in the equivalent proportion that sulphur would be used. The physical tests showed normal elongation, but only about 50% of the tensile strength of the analogous sulphur compound. All the samples showed but little deterioration on keeping, and after 4 years had the same elongation and about 70% of the original tensile strength. Doubling the proportion of selenium and using an organic accelerator did not give a better product, but caused the samples to become brittle on keeping, as in the case of over-vulcanised or under-vulcanised rubber. On removal from the press this product expanded 25% of its volume, which, however, became normal again when cold. This pointed to deficient vulcanisation. By using amorphous selenium and an organic accelerator some increase of tensile strength without loss of elongation was obtained. The best product obtained showed no appreciable deterioration when put on wire and left for 3 years. Accelerators were found which enabled rubber to be vulcanised by heating it with selenium at the ordinary vulcanising temperature (135° C.) for only about twice the time required with sulphur. The product showed the normal tensile strength (1100 to 1200 lb.) and elongation (2 to 10 or 12 in.) of a similar compound containing sulphur. It was somewhat soft, but did not deteriorate when heated for 1 days in the air at 70° C. It had rather low insulation resistance and dielectric strength. Chemical analysis as used with ordinary vulcanised compounds is not applicable to the selenium compounds, since black selenium is practically insoluble in acetone, and is only sparingly soluble in chloroform and carbon bisulphide. A compound to which 31.7% of rubber

had been added showed that amount of rubber when analysed by the tetrabromide method. Hence it would appear that no correction need be made for combined selenium or that the selenium is readily displaced by bromine. Rubber goods vulcanised with selenium appear to deteriorate much less with age than do sulphur compounds, so that where permanency is required it may be found advantageous to replace sulphur by selenium.—C. A. M.

XV.—LEATHER ; BONE ; HORN ; GLUE.

PATENT.

Tanning ; Compound suitable for —. O. Schmidt and A. Andres, Assignors to Badische Anilin und Soda Fabr., Ludwigshafen, Germany. U.S. Pat. 1,254,364, Jan. 22, 1918. Date of appl., Mar. 23, 1914.

SEE Addition of July 31, 1913, to Fr. Pat. 443,730 of 1912 ; this J., 1914, 209.

XVI.—SOILS ; FERTILISERS.

Soils ; Correlation between bacterial activity and lime requirement of —. F. E. Bear. Soil Sci., 1917, 4, 433—462.

THE author has studied the relation between the activities of soil bacteria concerned in nitrogen fixation or transformation and the lime requirement of certain soils, having lime requirements varying from 0 to 4600 lb. of calcium carbonate per 2,000,000 lb. of soil. Ammonification proceeded fairly satisfactorily in most of the soils without the application of lime, but the use of moderate amounts of calcium carbonate increased the rate of ammonification in most cases. The rate of nitrification was almost directly correlated with the amount of calcium carbonate supplied, soils having high lime requirements showing practically no nitrification until calcium carbonate was applied. Nitrogen fixation by non-symbiotic soil organisms was considerably increased by the addition of calcium carbonate, and the application of mono-calcium phosphate was also necessary for maximum nitrogen fixation. A good growth of soya beans was obtained on a soil having a lime requirement of 3000 lb., and well fertilised with acid phosphate (superphosphate) or manure. Nitrogen fixation accompanying the growth of soya beans took place readily in acid soils, but was increased by small applications of calcium carbonate, though decreased by large applications. The results, as a whole, indicate that small applications of calcium carbonate are, as a rule, relatively more effective than large applications as a means of increasing the bacterial activities in acid soils.—W. G.

Soils ; Moisture equivalent determinations of salt-treated — and their relation to changes in the interior surfaces. L. T. Sharp and D. D. Waynick. Soil Sci., 1917, 4, 463—469.

DUPLICATE 100-gram. portions of a clay loam soil were treated with 80 c.c. of solutions of different sodium salts. From one of these portions the salt was washed with distilled water before centrifuging, whilst a sample from the other portion was subjected to centrifuging without washing. It was found that there was a marked increase in the moisture equivalent (i.e., the water retained after centrifuging) after the treatment with saline solutions and washing, the extent of the increase

depending on the salt used. The greatest effect was obtained with sodium sulphate, followed in order by sodium hydroxide, sodium carbonate, and sodium chloride. This effect was not obtained when the washing with water was omitted. The authors consider that the salt and water treatment increased the interior surface of the soil by from 2 to 40 %, depending on the salt used.—W. G.

Soils; Relation of the mechanical analysis to the moisture equivalent of —. A. Smith. *Soil Sci.*, 1917, 4, 471—476.

MOISTURE equivalents (see preceding abstract) have been determined for the seven fractions obtained by the mechanical analysis of twelve different soils, and the values obtained were used to calculate the moisture equivalent of a number of soils from the results of their mechanical analyses. The calculated results were, on the whole, only approximations to the results obtained by actual determinations.—W. G.

Soils; Volumetric determination of sulphates in water extracts of —. A. W. Christie and J. C. Martin. *Soil Sci.*, 1917, 4, 477—479.

THE authors advocate the method of Raiziss and Dubin as used for the estimation of total sulphur in urine (see *J. Biol. Chem.*, 1914, 18, 297), the sulphates being precipitated as benzidine sulphate and the precipitate titrated with *N*/20 potassium permanganate. Not less than 15 c.c. and not more than 20 c.c. of water should be used to wash the benzidine sulphate precipitate. The average error by this method for the small amounts of water-soluble sulphates was found to be 3 % of the total.—W. G.

Nitrogen-assimilating bacteria [of soils]; Influence of nitrates on —. T. L. Hills. *J. Agric. Res.*, 1918, 12, 183—230.

SMALL quantities (up to 0.1 %) of potassium, sodium, or calcium nitrate caused a great increase in the number of *Azotobacter* in sterilised soil, but ammonium nitrate was less effective. Higher concentrations did not favour the growth of the organism. The presence of these nitrates caused an increase in the total nitrogen in the soil, but this increase was not commensurate with the increase in the numbers of *Azotobacter*. Slightly different results were obtained on agar films, calcium nitrate in this case causing a decrease in the amount of nitrogen fixed. In the presence of these nitrates marked pigmentation occurred and the volutin bodies in the *Azotobacter* cells increased in number and size. The number of *B. radicola* in sterilised soil was increased by the addition of small quantities of the three nitrates, the increase being less marked than in the case of *Azotobacter*, although the *B. radicola* appeared to be more resistant to higher concentrations of nitrates than *Azotobacter*. Unlike the *Azotobacter*, *B. radicola* does not reduce nitrate to nitrite under aerobic conditions. The presence of large amounts of the three nitrates proved detrimental to the formation of nodules on alfalfa. Nitrates in soil cultures prevented the re-formation of nodules once removed and also caused a decrease in the number of nodules already present.—W. G.

Root-nematode (Heterodera radicola); Study of the — and its control. W. P. Duruz. *Soil Sci.*, 1917, 4, 481—492.

NEMATODE activity was found to be diminished by excess of moisture, by high temperature (38.8° C.), and by treatment with formaldehyde, sphagnum moss extract, or sodium cyanide dissolved in water. The last named may be used on green-

house soils at the rate of 200 lb. per acre, dissolved in water so as to give $\frac{1}{2}$ gallon per sq. foot, the treatment being repeated at the end of one week. —W. G.

PATENTS.

Peat and muck; Process of treating — for the preparation of fertiliser. J. P. Schroeder, Washington, D.C. U.S. Pats. (A) 1,254,365 and (B) 1,254,366, Jan. 22, 1918. Dates of appl., Aug. 13 and 22, 1917. (Dedicated to the public.)

(A) RAW peat is digested with sulphuric acid, the complex, insoluble proteins of the peat being thereby hydrolysed giving simple compounds, soluble in water and available for plant use. The excess acid is then neutralised by the addition of finely ground rock phosphate. The material is thus obtained in a physical condition suitable for application to the soil. (B) Peat is made slightly alkaline with ammonia and digested under steam pressure, the insoluble proteins being hydrolysed into simple compounds soluble in water. With this material there may then be intimately mixed a small portion of ammonium sulphate and calcium carbonate, which slowly interact and generate ammonia throughout the mass, thus neutralising any tendency to revert to an acid reaction.—W. G.

XVII.—SUGARS; STARCHES; GUMS.

Sucrose; Influence of different compounds on the destruction of monosaccharides by sodium hydroxide and on the inversion of — by hydrochloric acid. III. Constitutional formulæ of the hydroxybenzoic acids and of sulphanilic acid. H. I. Waterman. *Proc. K. Akad. Wetensch. Amsterdam*, 1918, 20, 581—589.

SALICYLIC acid behaves as a monobasic acid in retarding the destruction of dextrose by sodium hydroxide, whereas *m*- and *p*-hydroxybenzoic acids behave as dibasic acids. Sulphanilic and hippuric acids behave as monobasic acids in this reaction, but exert no influence on the inversion of sucrose by hydrochloric acid. (For the constitutional formulæ see *J. Chem. Soc.*, April, 1918.)—W. G.

PATENTS.

Size and process of making the same [from starch]. A. W. H. Lenders, Cedar Rapids, Iowa. U.S. Pat. 1,253,397, Jan. 15, 1918. Date of appl., July 8, 1916.

SIZE containing a mixture of thick-boiling with thin-boiling starch or of modified starch with a lubricant, may be prepared by modifying starch with acid to produce a thin-boiling product, which, after addition of raw starch if necessary, is again modified by alkaline treatment.—J. H. L.

Production of decolorising charcoal. Eng. Pat. 106,089. See 11B.

XVIII.—FERMENTATION INDUSTRIES.

Wines; White "casse" of —. L. Moreau and B. Vinet. *Bull. Soc. Agric. France*, 1917, 267—271, 292—299. *Bull. Agric. Intell.*, 1917, 8, 1280—1281.

FROM a study of numerous wines affected by white "casse" the authors conclude that the malady is brought about by the presence of iron and phosphoric acid (cp. Laborde, this *J.*, 1917, 468). Free tartaric acid favours the development of the

disease, de-acidified wines being nearly always immune. Acid potassium tartrate, and malic and succinic acids have far less influence than free tartaric acid. The malady may be prevented in all cases by addition of 1 grm., and in some cases by addition of 0.5 grm., of citric acid per litre, but even the larger amount does not always dissolve the precipitate when it has once formed, though it promotes agglutination and deposition of the suspended ferric phosphate. In a wine affected with white "casé" the tannin present perceptibly aggravates the disease and produces a bluish colour. Such cases, however, should be distinguished from blue "casé," in which the precipitate contains no phosphoric acid or only traces. Aeration tends to promote the development of white "casé," by oxidising ferrous to ferric phosphate, which then separates from solution. The disease can be prevented or cured in two ways, viz., by treating wines of average or less than average acidity with citric acid, and by treating "green" wines with de-acidifying agents. As a preventive measure it is very desirable to practice the de-acidification of musts in years when these have a high acidity.—J. H. L.

Use of micro-organisms to determine the preservative value of spices. Bachmann. See XIXA.

Alcohol from calcium carbide. Beyer. See XX.

PATENTS.

Fermenting tun; Method of and apparatus for preventing overflow of surface bubbles in a —. R. G. Abercrombie. Alloa. Eng. Pat. 113,002, Feb. 9, 1917. (Appl. No. 1976 of 1917.)

HORIZONTAL, fan-shaped films of fluid, e.g., air, are ejected across the surface of the fermenting liquid, from a number of nozzles, e.g., four, fixed around the top of the tun and in communication with a supply of the compressed fluid.—J. H. L.

Heating and boiling liquids [e.g., wort]; Means for —. P. Robinson. Burton-on-Trent. Eng. Pat. 113,346, Mar. 7, 1917. (Appl. No. 3348 of 1917.)

An apparatus for fixing in a copper for boiling wort consists of a central hollow hub divided into two compartments one above the other, and having an inlet for the supply of live steam to the lower one and an outlet for condensed water from the upper compartment. Radial tubes project from the central hub and each is divided by a horizontal diaphragm into a lower live steam compartment and an upper condensed water compartment. Upright open tubes are fixed in holes in the diaphragm and open into the live steam compartment, and are surrounded by wider tubes with closed tops which open below into the condensed water compartment.—J. H. P.

Ferments and process of making the same. A. D. Barr. McHue, Ark. U.S. Pat. 1,253,334, Jan. 15, 1918. Date of appl., June 3, 1916.

CLAIM is made to a ferment (enzyme) containing an amino-acid, possessing proteolytic power, and capable of decomposing carbohydrates in acid, neutral, or alkaline media with production of acid substances, also to products comprising an enzyme (or a mixture of proteolytic enzymes) together with leucine, e.g., a mixture of equal amounts of pepsin and pancreatin with 5% of leucine. Products capable of decomposing carbohydrates are prepared by triturating a mixture of proteolytic enzymes, adding a small quantity of a substance containing the amino-acid group, and again triturating the mixture.—J. H. L.

Amino compounds [for foodstuffs, etc.]; Preparation of — by fermentation. G. Eberle, Stuttgart, Germany. U.S. Pat. 1,254,033, Jan. 22, 1918. Date of appl., Feb. 15, 1915.

SEE Fr. Pat. 476,693 of 1914; this J., 1916, 631.

XIXA—FOODS.

Dialysis; Gliding —. II. [Preparation of fruit syrups.] II. Thoms. Ber., 1918, 51, 42—45.

DIALYSIS can be greatly accelerated if the liquid is made to glide over the membrane. For this purpose, an apparatus may be constructed of two vessels, clamped together, with a parchment membrane between them, water being placed on one side and the liquid on the other. The apparatus is rotated or shaken in the same plane as the membrane. Such a device has been designed by the author for the preparation of stable fruit syrups, without the destruction of the enzymes, vitamins, or aroma, merely by removing the excess of acids and sugar. (See also J. Chem. Soc., 1917, ii, 561; and April, 1918.)—J. C. W.

Spices; Use of micro-organisms to determine the preservative value of —. F. M. Bachmann. J. Ind. Eng. Chem., 1918, 10, 121—123.

BACTERIA, yeasts, and mould-fungi were grown on nutrient media containing definite amounts of different brands of cloves, cinnamon, and all-spice. It was found that there was a considerable difference in the preservative effect of different brands of the same spice, and that the method could be used as a criterion of the preservative value. The results showed that cloves may be as effective a preservative as cinnamon.—C. A. M.

Haystacks; Spontaneous ignition of —. E. Jordi. Schweiz. Chem.-Zeit., 1918, 2, 7—10.

SINCE about 1913, haystack fires have been much more frequent than before in Switzerland, probably because modern mechanical appliances enable hay-making and stacking to be completed much more rapidly than was formerly the case and in consequence the hay often has less opportunity to dry. The author refers to the work of various investigators, viz., Miebe, Ranke, Schenk, and Boekhout and de Fries, on the heating of stacks, and concludes therefrom that a rise in temperature to 40° C. may occur owing to respiration of the surviving cells and also to intramolecular respiration; the activities of micro-organisms account for further heating to about 70° C., at which temperature a slow process of dry distillation may set in and eventually heat the stack to 300°—400° C. The final products of this dry distillation are combustible gases and carbon, the latter being pyrophoric owing to the fibrous nature of the original material. Various practical precautions are enumerated; e.g., care should be taken that hay is dry when stacked; stacks should be of as large cross-section as possible, and provided with means for ventilation. If the temperature in the stack should rise to 70° C. the ventilation passages should be closed. Salt may be scattered over hay which has become damaged by exposure to bad weather.—J. H. L.

Haystacks; New theory of the spontaneous firing of —. A. Tschirch. Schweiz. Chem.-Zeit., 1918, 2, 10—12.

THE author criticises the commonly accepted theory of spontaneous combustion in stacks, especially the assumption that combustible gas and carbon are produced at relatively low temperatures by "dry distillation." He proposes a

theory based on observations made on the drying of medicinal plants. The first phase of heating is regarded as due to oxidation processes under the influence of the plant oxidases and at the expense of the air present in the stack. This phase results in a small rise of temperature but ceases when the oxygen in the stack has been exhausted. After this the chief rôle is played by reductases, which act energetically between 50° and 70° C. and effect the de-oxidation and eventual carbonisation of such substances as amino-acids and carbohydrates. It is to the accumulation of oxygen withdrawn by the reductases that the danger of ignition is due, for the reduction processes themselves would not produce sufficient heat to ignite the material. The general precautionary measures recommended are, therefore, thorough drying of the hay before stacking (to minimise enzymic action), and thorough aeration of the stacks, which may be built in horizontal layers with air spaces between.

Seeds of Echinocystis oregana. Daughters. See XII.

PATENTS.

Milk; Apparatus for evaporating—. J. H. Mason, Prince Rupert, B.C., Canada. U.S. Pat. 1,254,423, Jan. 22, 1918. Date of appl. Aug. 2, 1916.

The apparatus comprises a drying chamber and an evaporating reservoir, with a pipe for conveying air from the drying chamber to the evaporating reservoir and a return pipe. The drying chamber contains a refrigerating brine coil for dehydrating the air by freezing the moisture in it. Means are provided for spraying water on to the coil, and for passing heat through it when the drying chamber is disconnected from the evaporating reservoir.—J. H. J.

Garbage; Process of converting—into food. W. H. Faust, Assignor to M. E. Faust, Los Angeles, Cal. U.S. Pat. 1,254,317, Jan. 22, 1918. Date of appl., May 16, 1917.

GARBAGE is cooked and dried for a long period at about 212° F. (100° C.), and then heated to about 400° F. (205° C.) for a short time to destroy micro-organisms. The material is then ground into granular form.—W. F. F.

Bread and the like; Process for predetermining the time necessary for the fermentation or rising of dough for—. A. Watkins, Hereford. U.S. Pat. 1,254,457, Jan. 22, 1918. Date of appl., Aug. 24, 1915.

SEE Eng. Pat. 19,487 of 1914; this J., 1915, 243.

Coffee extract; Plant for the manufacture of—. L. Etaix, Paris. U.S. Pat. 1,254,129, Jan. 22, 1918. Date of appl., Aug. 31, 1916.

SEE Eng. Pat. 2722 of 1915; this J., 1915, 1268.

XIXB.—WATER PURIFICATION; SANITATION.

Cresols; Process for the deodorisation of the—. J. F. Couch. Amer. J. Pharm., 1918, 98, 128—130.

EQUAL weights of cresol and concentrated sulphuric acid are thoroughly mixed and heated to 75°—

110° C. until a drop of the liquid mixed with water gives only a faint cloudiness. The separation of oily drops shows that the reaction is incomplete unless the cresol contains a large proportion of hydrocarbons. The length of time necessary for the reaction varies between 6 and 14 hours. On completion of the reaction, the product is poured into five volumes of cold water, any oil which separates out being removed. The mixture is neutralised with milk of lime and, after standing for 24 hours, the clear liquid is decanted off. The sediment is washed and the washings added to the decanted liquid. The solution is then evaporated to dryness on the water-bath, the residue dissolved in a little water, and if the odour still persists, the solution must be again evaporated to dryness. When the solution in water is quite odourless, it is diluted with water to twice the volume of the cresol taken, and the calcium precipitated with sulphuric acid, carefully avoiding any excess. After standing for a day, the solution is filtered and the sediment washed; the filtrate may then be made up to any desired strength. Tests with *B. coli* show that the phenol coefficient of the solution is considerably increased by this treatment, and since no addition of soap is necessary in the solution, it will not become cloudy when mixed with hard waters. It may be used in all cases in place of the *Liquor cresolis compositus* and in the same proportions.—L. A. C.

Formaldehyde; A substitute for the permanganate-formalin method of disinfection with—. C. G. Storm. J. Ind. Eng. Chem., 1918, 10, 123—124.

If formalin be poured on to crystals of potassium or sodium chlorate there is no reaction until the mixture is heated to about 65° C. The reaction which then occurs is analogous to that which takes place between formaldehyde and potassium permanganate in the cold, and appears to be in accordance with the equation:

although probably other reactions such as:

also occur. The best results for disinfection are obtained by the use of 25 grms. of chlorate to 100 c.c. of formalin; with these proportions about 23% of the formaldehyde is oxidised, and the remainder volatilised.—C. A. M.

Quinine derivatives; Disinfectant action of—on diphtheria bacilli. H. Schaeffer. Biochem. Zeits., 1917, 83, 269—314.

THE antiseptic and disinfectant properties of the alkyl derivatives of hydrocupreine increase, generally, with rise in molecular weight of the alkyl group up to the octyl derivatives, after which they diminish. The antiseptic and disinfecting actions are not always absolutely parallel. (See also J. Chem. Soc., March, 1918.)—S. B. S.

PATENTS.

Water or sewage or other liquids; Apparatus for and processes relating to purifying or treating—. C. F. Wallace, Richmond, N.Y., and M. F. Tiernan, New Rochelle, N.Y., U.S.A. Eng. Pat. 113,105, Nov. 14, 1916. (Appl. No. 16,281 of 1916.)

THE process is specially devised for the treatment of water with chlorine, a supply of which is obtained from two cylinders of the liquefied gas connected to the apparatus with flexible tubing. The water to be treated passes through a Venturi meter, from each side of which a pipe passes to a differential pressure-regulating apparatus contain-

ing either two or three diaphragm chambers. The high and low pressures respectively of the Venturi meter are transmitted by the pipes to each side of the central diaphragm. The chlorine is supplied to a drop pressure control valve (see following abstract), and the high and low pressure gas is supplied to the two outer diaphragms. The apparatus is set so that the pressure difference of the gas supply maintains the required proportion to the pressure difference of the water supply. When this is disturbed, the diaphragms react upon the stem of a needle-valve on the main gas supply pipe, the action of which permits more or less chlorine to pass to the control valve. The chlorine after leaving the control valve passes to a flow indicator and meter of the type described in Eng. Pat. 113,197 (following). From this, the gas passes through a back-pressure valve of the type described in Eng. Pat. 113,198 (following) to a diffuser in the water main. Various modifications of the apparatus are described.—J. H. J.

Liquids; Treatment of— with gases. C. F. Wallace, Richmond, N.Y., and M. F. Tiernan, New Rochelle, N.Y., U.S.A. Eng. Pat. 113,106, Nov. 14, 1916. (Appl. No. 16,282 of 1916.)

THE process refers more especially to the treatment of water with chlorine in a regulated, constant amount. The gas is supplied from compressed gas cylinders and is passed through a differential pressure-reducing valve which is a simplified form of the similar valve described in the preceding abstract. The exit pipe from the valve leads to a control valve which consists of a needle-valve under which the gas has to pass before reaching the exit tube. The stem of the needle is screw-threaded and passes through a gland nut, and engages with a sleeve screwed externally and internally with threads of slightly different pitch. The head of the sleeve is adapted to be turned by a key, a comparatively large movement being required to effect a fine adjustment of the needle-valve. The exit pipe carries a by-pass to the diaphragm of the preceding valve, the action of which regulates the pressure of the chlorine supply to the control valve, so as to maintain the drop in pressure across this valve constant. From the control valve the gas passes through a meter into an absorption apparatus, in which a solution is made for delivery to the bulk of water to be treated.—J. H. J.

Gases; Devices for indicating and measuring the flow of— C. F. Wallace, Richmond, N.Y., and M. F. Tiernan, New Rochelle, N.Y., U.S.A. Eng. Pat. 113,197, Nov. 14, 1916. (Appl. No. 6173 of 1917.)

THE apparatus consists of a pipe connected to the gas supply to be measured, the free end of the pipe being covered with a transparent cap with a constricted orifice. Over this cap is another larger, transparent cap, through which the gas passes to the exit pipe. Narrow tubes pass from the inlet and exit pipes to the two limbs of a manometer, of the pattern in which one limb is placed inside the other. The inlet pipe is connected to the wider limb and the exit pipe to the narrow limb. The latter limb carries an enlarged cup at its upper end to act as a safety reservoir for the indicating liquid, should it be forced up the narrow limb by a sudden increase of pressure. A scale is placed behind the two limbs of the manometer, indicating the pressure difference in the two pipes corresponding to the difference in level of the liquid in the two limbs, or the corresponding rates of flow. In lieu of the cap with the constricted orifice, a cap with a porous diaphragm may be used. The apparatus is specially suited for measuring the flow of chlorine when used for the purification of water.—J. H. J.

Valves employed in systems supplying gases such as chlorine to liquids such as water. C. F. Wallace, Richmond, N.Y., and M. F. Tiernan, New Rochelle, N.Y., U.S.A. Eng. Pat. 113,198, Nov. 14, 1916. (Appl. No. 6174 of 1917.)

THE apparatus consists of a casing and a cover, a diaphragm being clamped between the two. Attached to the lower side of the diaphragm is a needle-valve operating in a seating which communicates with the exit pipe. Above the diaphragm is a spring, regulated by a set screw in the cover of the apparatus. The space below the diaphragm is divided into two parts by a cup surrounding the needle-valve. The gas to be used is admitted to the space below the cup and passes through a strainer into the cup by means of holes around the rim of the cup. When the pressure of the gas in the cup is greater than that of the spring above the diaphragm, the needle-valve is opened and the gas passes into the exit pipe. The cup serves to retain any liquid flowing back through the valve. In lieu of the spring above the diaphragm, a volume of air confined at a definite pressure may be used. This has the advantage that the pressures on each side of the diaphragm are affected equally by any rise of temperature.—J. H. J.

Purifying water; Apparatus for and process of treating liquids with gases or — C. F. Wallace, Richmond, N.Y., and M. F. Tiernan, New Rochelle, N.Y., U.S.A. Eng. Pat. 113,288, Nov. 14, 1916. (Appl. No. 16,283 of 1916.)

THE process is particularly applicable to the preparation of a chlorine solution for use in the purification of water. The supply of chlorine is obtained from a cylinder of the liquefied gas, and is delivered to a differential pressure reducing valve of the type described in Eng. Pat. 113,106 (preceding). The gas at the reduced pressure passes through a back pressure valve of the type described in Eng. Pat. 113,198 (preceding) into an absorption vessel. This is made of glass with an air-tight cover, and in the centre a bell-jar is held in place, containing an inverted siphon with its exit pipe opening through the shoulder of the bell-jar. The absorption vessel is kept nearly full of water, which enters under pressure through a constricted opening in the cover. The exit pipe from the back pressure valve passes through the cover and opens into the top of the bell-jar, and the entering chlorine fills the bell-jar until the siphon comes into action, discharging the gas into the water in the outer part of the vessel. The exit pipe for the solution is placed vertically in the vessel, with its upper end slightly above the level of the top of the bell-jar. The absorption vessel being of glass, the discharges from the bell-jar can be counted.—J. H. J.

Diffusers for use in diffusing gases in liquids. [Purification of water.] C. F. Wallace, Richmond, N.Y., and M. F. Tiernan, New Rochelle, N.Y., U.S.A. Eng. Pat. 113,374, Nov. 14, 1916. (Appl. No. 6175 of 1917.)

THE diffuser consists of a shallow closed dish of porcelain, the top plate being made of alundum or other porous material. The bottom of the dish has a small disc let into it, made of material of finer porosity than the top plate. The diffuser is specially designed for use in flowing water in which chlorine is to be dissolved, as described in Eng. Pat. 113,105 (preceding). The diffuser is placed below the water level and the chlorine enters under pressure by a silver pipe passing through the top plate, and escapes through the pores of the material of the top plate. Any water collecting inside the diffuser is expelled through the porous disc in the bottom.—J. H. J.

Sewage and other liquids : Purification of —. W. Jones, Stourbridge, Worcestershire, and Jones and Attwood, Ltd., Amblecote, Staffs. Eng. Pat. 113,333, Feb. 26, 1917. (Appl. No. 2761 of 1917.)

AN improved form of tank for use in the activated sludge process consists of a long channel arranged as the outer coils of a spiral, with air diffusers arranged along its length, either in the middle of the channel or at one side or both sides. The floor is made to slope towards the air diffusers. The channel may be restricted in width at each end or at the position of the air diffusers by baffles projecting from the side walls. The channel terminates at the centre in a round tank with a conical bottom, not furnished with air diffusers, in which the sludge settles at the bottom and is returned by an air lift or other means to the crude sewage inlet of the channel. Another form of the channel consists in a to and fro rectangular arrangement with the deposit tank at one end. —J. H. J.

Activated [sewage] sludge treatment. W. C. Moor, Fort Worth, Tex., Assignor to Armour and Co., Chicago, Ill. U.S. Pat. 1,254,833, Jan. 29, 1918. Date of appl., July 9, 1917.

ACTIVATED sludge is dehydrated by heating above 30° C. and is then coagulated by addition of sulphuric acid. The gas generated on coagulation causes the coagulum to float; it is separated and dried. —J. H. J.

Activated [sewage] sludge treatment. G. B. Mulloy, Assignor to Armour and Co., Chicago, Ill. U.S. Pat. 1,254,836, Jan. 29, 1918. Date of appl., July 9, 1917.

IN treating industrial sewage by the activated sludge process, the sewage is submitted to a preliminary dilution with the effluent from previously treated sewage. —J. H. J.

Activated [sewage] sludge treatment. G. L. Noble, Assignor to Armour and Co., Chicago, Ill. U.S. Pat. 1,254,841, Jan. 29, 1918. Date of appl., July 9, 1917.

IN the activated sludge process of sewage treatment, the raw sewage is inoculated with activated sludge from previously treated sewage, which sludge has been withdrawn from the sewage and aerated for about three hours. —J. H. J.

Polysulphide solutions [insecticides]; Method of treating —. E. C. Holton, Olmsted Falls, Assignor to The Sherwin-Williams Co., Cleveland, Ohio. U.S. Pat. 1,254,908, Jan. 29, 1918. Date of appl., Dec. 1, 1915.

THE polysulphide solution is prepared of 35°–40° B. strength and 1%–5% of its weight of cane sugar or of an alkaline-earth saccharate is added to it. The solution is then evaporated to dryness and the residue is pulverised. The product contains lime-sulphur and sugar in the ratio of 8:1, and can be used as an insecticide. —J. H. J.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Alcohol from calcium carbide; Ethyl —. O. Beyer, Schweiz. Chem.-Zeit., 1918, 2, 12–13.

IT is well known that acetylene can be converted into acetaldehyde by the use of certain catalysts, and the aldehyde can be reduced to alcohol by

hydrogen in presence of finely divided nickel, platinum, or palladium. In Switzerland the production of alcohol from calcium carbide has been undertaken on a manufacturing scale, and owing to the low cost of electrical power the product is expected to compete successfully with spirit produced by fermentation. —J. H. J.

Influence of different compounds on the destruction of monosaccharides by sodium hydroxide and on the inversion of sucrose by hydrochloric acid. 111. *Constitutional formulae of the hydroxybenzoic acids and of sulphanilic acid.* Waterman. See XVII.

PATENTS.

Diallylbarbituric acid and alkaloids of the morphine series; Compounds derived from — and process of making same. P. Hüssy and W. Föhrenbach, Assignors to Soc. Chem. Ind. in Basle, Switzerland. U.S. Pat. 1,255,423, Feb. 5, 1918. Date of appl., Apr. 9, 1917.

SEE Eng. Pat. 107,409 of 1916; this J., 1917, 979. The compounds are easily soluble in hot water, alcohol, methyl alcohol, acetone, and ethyl acetate, and insoluble in petroleum spirit. The compound from diallylbarbituric acid and ethylmorphine is a white, crystalline substance melting at 285° C.

Anæsthetic bodies. Parke, Davis, and Co., Assignees of L. Thorp, Detroit, Mich., and E. A. Wildman, Indianapolis, Ind., U.S.A. Eng. Pat. 105,746, Feb. 27, 1917. (Appl. No. 2928 of 1917.) Under Int. Conv., Apr. 17, 1916.

SEE U.S. Pat. 1,193,651 of 1916; this J., 1916, 979.

Anæsthetic bodies. Parke, Davis, and Co., Assignees of L. Thorp, Detroit, Mich., U.S.A. Eng. Pat. 106,087, Feb. 27, 1917. (Appl. No. 2896 of 1917.) Under Int. Conv., Apr. 24, 1916.

Glutamic acid; Process to separate — from other amino acids. A. Corti, Dübendorf, Switzerland. U.S. Pat. 1,255,390, Feb. 5, 1918. Date of appl., Dec. 8, 1916.

SEE Eng. Pat. 106,081 of 1916; this J., 1917, 979.

XXIII.—ANALYSIS.

Permanganate solutions; Preparation of N/100 —. J. O. Halverson and O. Bergeim. J. Ind. Eng. Chem., 1918, 10, 119–120.

THE preparation of weak standard solutions of potassium permanganate by diluting stronger solutions is inaccurate, owing to the presence of organic matter in the distilled water. By means of the following method N/100 potassium permanganate solutions which will retain their strength indefinitely may be prepared. A solution of 0.4 gm. of pure potassium permanganate crystals in a litre of re-distilled water is digested for 36 hours near its boiling point in a flask which has been rinsed with the same water. After cooling, and standing over night, the supernatant liquid is filtered with the aid of suction through a Buchner funnel lined with ignited asbestos, and kept in the dark in a bottle, free from organic matter. After standing 2 to 3 days, the solution is standardised by adding 10 c.c. of 10% sulphuric acid, rendered faintly pink with permanganate, to 10 c.c. of N/50 oxalic acid solution, placing the vessel in a water bath at 65° C. for a few minutes, and titrating it with the permanganate solution. A correction is obtained by titrating 10 c.c. of the sulphuric acid diluted with the same volume of water. —C. A. M.

Standardisation of chemical stonecare. Nielsen and Garrow. See VIII.

PATENTS.

Continuous-rectification apparatus ; Cooling plates for —. E. Barbet et Fils et Cie., Paris. Eng. Pat. 105,549, Mar. 8, 1917. (Appl. No. 3444 of 1917.) Under Int. Conv., Mar. 27, 1916.

A COOLING plate for rectifying columns consists of a concave basin with a central chimney, hood, and overflow, and a superposed perforated plate. A cooling coil is immersed in the reflux liquid which collects on the upper side of the perforated plate. The perforations of the plate are confined to the neighbourhood of the cooling coil.—W. H. C.

Grinding machines. G. Bamburg, London. Eng. Pat. 113,677, Mar. 9, 1917. (Appl. No. 3492 of 1917.)

A MACHINE for grinding resinous or fatty substances, or other materials which tend to clog the machine, comprises a drum formed by mounting a number of split wooden pulley wheels of large face area close together on a shaft. Rasping plates are fixed to the outer periphery of the drum, and a wooden hopper closely surrounds the drum so that only fine particles can fall between the drum and the hopper. An inclined baffle-plate is mounted on the side of the hopper facing the direction of the revolving rasping drum. It may have a rasping surface or may be smooth, and it is heavily backed with wood to lessen vibration. The material is admitted through a door in the hopper and is forced by the revolving rasps against the fixed baffle. The powder produced passes between the drum and the hopper into a receptacle underneath.—J. H. P.

Attrition mill. E. P. Alsted, Truesdell, Wis. U.S. Pat. 1,255,845, Feb. 12, 1918. Date of appl., Sept. 13, 1916.

THE mill comprises opposed rotating plates provided with radial ribs, the working edges of which are undercut and converge towards the axis of the plates for a portion of their length and are parallel to each other at other portions of their length so as to advance the line of cutting engagement of the ribs towards the periphery of the plates for a portion of the length of the ribs and towards the axis along other portions of the ribs. Portions of the radial ribs are bevelled towards the plates. Inner and outer transverse ribs extend across the radial ribs, the inner rib being eccentric to and the outer rib concentric with the axis of the plate. During rotation the inner transverse ribs of opposite plates partly overlap each other to permit the passage of material from pockets inclosed within the ribs to pockets outside.—J. H. P.

Gases ; Evacuation and compression of —. E. S. G. Rees, Stafford. U.S. Pat. 1,252,178, Jan. 1, 1918. Date of appl., May 17, 1915.

A ROTARY air pump has its suction connected with the vessel to be exhausted and also with the water space of a sealed receptacle partly filled with water maintained at a comparatively low temperature. The evacuated air is delivered into the sealed receptacle by the pump and is withdrawn therefrom and delivered to the atmosphere by a second rotary air pump, the suction of which is connected with a second supply of water.

—W. H. C.

Separation of suspended particles from gases : Apparatus for electrical —. W. A. Schmidt and G. C. Roberts, Assignors to International Precipitation Co., Los Angeles, Cal. U.S. Pat. 1,252,183, Jan. 1, 1918. Date of appl., Sept. 9, 1913.

THE gas is passed from a flue through a number of vertical, tubular, collecting electrodes within each of which a flexible ionising electrode is suspended concentrically. The ends of the central electrodes are enlarged where they leave the tubes to reduce the surface field intensity at these points.

—W. H. C.

Dryer [for fibrous materials]. F. G. Sargent, Westford, Mass., Assignor to C. G. Sargent's Sons Corporation, Graniteville, Mass. U.S. Pat. 1,254,073, Jan. 22, 1918. Date of appl., June 4, 1917.

THE material to be dried is fed intermittently by a reciprocating feed apron on to a reciprocating conveyor within a casing. The material is fed only on the forward stroke of the conveyor. Swinging "kicker arms" are provided above the conveyor to loosen the material.—W. H. C.

Dry-kiln. H. Hunter, Assignor to The Hunter Dry Kiln Co., Indianapolis, Ind. U.S. Pat. 1,254,142, Jan. 22, 1918. Date of appl., Feb. 12, 1917.

THE kiln consists of a closed rectangular chamber having a partition, spaced from one side wall, depending from the ceiling to a point near the floor. A second partition is spaced between the first partition and the adjacent wall and extends upwards from the floor to a point near the ceiling. A heating coil is arranged in the space between the second partition and the wall. Air enters through the wall near the bottom, passes upwards over the heater and then descends between the partitions and enters the main compartment of the chamber below the inner partition. Each partition consists of a number of doors, those of the partition nearer the wall being hinged at the bottom and those of the other partition at the top.—W. H. C.

Drying apparatus. J. L. Pierce, Assignor to Pacific Commercial Co., Manila, Philippine Islands. U.S. Pat. 1,254,431, Jan. 22, 1918. Date of appl., Dec. 28, 1916.

A NUMBER of superposed conveyors, each provided with a heating unit, are arranged within a casing. Heated air is supplied to the heating units, and products of combustion are also supplied to supplement the heated air without mixing with it.

—W. H. C.

Dryer. T. G. Haney, New London, Conn. U.S. Pat. 1,255,162, Feb. 5, 1918. Date of appl., June 18, 1917.

THE material to be dried is passed through the drying chamber on a reticulated conveyor, and is dried by heated air which is passed over the upper run of the conveyor and is then prevented from coming into contact with the air entering the heater.—W. H. C.

Drying apparatus. J. B. Adt, Baltimore, Md. U.S. Pat. 1,255,843, Feb. 12, 1918. Date of appl., July 17, 1917.

A ROTARY drying drum has an inlet for the material to be dried and an air outlet at one end and a material outlet and air inlet at the opposite end. The latter end of the drum extends into an air-expansion chamber into which it opens, and a heating jacket surrounds the drum and the opening into the air-expansion chamber. The jacket is carried by the drum and rotates with it. At the end remote from the expansion chamber a header

is provided and this communicates with the jacket. Air is delivered from an air heater into the header.—J. H. P.

Refrigerating apparatus, and oil separator and condenser mechanism therefor. *Refrigerating apparatus.* B. S. McClellan, Chicago, Ill. U.S. Pats. (A) 1,254,518 and (B) 1,254,519, Jan. 22, 1918. Dates of appl., Dec. 23 and 31, 1915. Renewed Apr. 19 and Oct. 6, 1917.

(A) A CONDENSER chamber having a gas inlet communicating with the compression chamber of a compressor and a sealed outlet for refrigerating liquid, is provided with a water cooling coil and is surrounded by an outer cooling chamber through which water is circulated. (B) A compressor having an oil reservoir for lubricating the compressing mechanism, delivers a volatile fluid to a condenser, whence the condensed liquid flows to an expansion valve casing provided with an expansion chamber and thence to an expansion coil, which in turn communicates with the compression chamber of the compressor. Below the expansion chamber is a reservoir in which oil separated from the volatile fluid in the expansion chamber collects and whence it is returned to the oil reservoir of the compressor.—W. H. C.

Refrigerating apparatus. O. E. Bornhauser and J. E. Herman, Assignors to The Wagner Refrigeration Co., Sandusky, Ohio. U.S. Pat. 1,255,505, Feb. 5, 1918. Date of appl., Dec. 15, 1917.

A REFRIGERATING apparatus of the intermittent absorption type is provided with a hydraulic diaphragm, controlled by the level of the liquid in the receiver, which serves to regulate the supply of water and gas to the apparatus.—W. H. C.

Refrigerating apparatus. O. E. Bornhauser. Assignor to J. E. Herman and C. L. Wagner, Sandusky, Ohio. U.S. Pat. 1,255,286, Feb. 5, 1918. Date of appl., Feb. 19, 1917.

THE apparatus is of the intermittent absorption type and consists of an ammonia generator-absorber with a burner and gas supply, a condenser with a water circulating system for the ammonia gas, and a receiver for the liquid ammonia. A cooling coil included in a by-pass from the condenser system is placed in the liquid container of the generator-absorber. The level of the liquid ammonia in the receiver actuates a device for regulating the gas supply and for throwing the by-pass to the cooling coil out of or into action, according as the generator-absorber is acting as a generator or an absorber. The water supply in the condenser system is regulated by a thermostatic connection actuated by the temperature of the liquid in the generator-absorber. The temperature of the generator-absorber also controls a valve on the gas supply pipe which cuts off the gas when the temperature exceeds a predetermined point, and automatically locks the valve so that it cannot be reopened except by hand.—J. H. J.

Refrigerating apparatus. M. F. Ewen, Chicago, Ill. Assignor to Larsen Ice Machine Co. (Inc.), Wilmington, Del. U.S. Pat. 1,255,723, Feb. 5, 1918. Date of appl., Jan. 4, 1915.

A POSITIVELY operated valve is interposed between the condenser-receiver and the expansion chamber of the apparatus. The valve is operated by the pump which transfers the absorbent to the still at predetermined intervals.—W. H. C.

Centrifugal machine. U. F. S. Hartman and A. H. La Casse, Crockett, Cal. U.S. Pat. 1,255,007, Jan. 29, 1918. Date of appl., May 22, 1917.

THE frustum-shaped basket of the machine has segmental discharge ports formed in the base and is connected by means of a spider to a hollow

vertical shaft, driven from above, by which it is rotated. The ports are closed when the basket is rotating by a bottom piece supported by an inner shaft passing through the hollow shaft and which is raised or lowered by a lever arm.—W. H. C.

Boiler feed-water; Method of and apparatus for treating—. H. C. Heaton, Chicago, Ill. Assignor to The Babcock and Wilcox Co., Bayonne, N.J. U.S. Pat. 1,255,164, Feb. 5, 1918. Date of appl., Dec. 8, 1914.

THE feed-water is passed through the low-pressure stage of a multi-stage economiser and then withdrawn along with any air or gases into a tank where the air and gases are separated. The water is then heated by exhaust steam and passed through the high-pressure stage of the economiser into the boiler.—W. H. C.

Steam-boiler economiser and method of operating the same. D. S. Jacobus, Jersey City, N.J., Assignor to The Babcock and Wilcox Co., Bayonne, N.J. U.S. Pat. 1,255,170, Feb. 5, 1918. Date of appl., Dec. 8, 1914.

IN using artificially softened or naturally soft water in a boiler, the main supply of water is passed through a section of an economiser: it is then mixed with the hot concentrated liquid from the boiler, and the mixture is passed through another section of the economiser, at a higher pressure, into the boiler.—W. H. C.

[Agitating] barrel. J. L. Malm, Assignor to The Midwest Metals Co., Denver, Colo. U.S. Pat. 1,255,196, Feb. 5, 1918. Date of appl., Apr. 26, 1915.

A HOLLOW cylinder rotating on a horizontal axis is closed at one end and connected to a source of fluid pressure at the other end. A series of longitudinal baffles is provided on the inner cylindrical wall, the baffles being connected by filter sheets so as to form a series of chambers to receive the filtrate and then discharge it. A discharge door for solid material is provided in the cylindrical wall midway between the ends, and additional baffles converge spirally from both ends towards the discharge door to collect and facilitate discharge of the filtered material. In a modification, a number of discharge doors are provided, each having a set of converging spiral baffles on each side of it.—W. F. F.

Evaporator. G. H. Benjamin, New York. U.S. Pat. 1,255,502, Feb. 5, 1918. Date of appl., Mar. 30, 1917.

A VERTICAL cylindrical casing is provided with a feed pipe, blow-off pipe, and vapour discharge pipe. The heating element projects into the casing and is mounted on a detachable door secured over an opening in the casing, the door and heating element being supported wholly by means outside and independent of the casing.—W. F. F.

Absorbing a fixed quantity of gas by a liquid; Apparatus for—. G. Braam, Rotterdam, Netherlands. U.S. Pat. 1,256,291, Feb. 12, 1918. Date of appl., Dec. 1, 1917.

AN absorption vat provided with means for agitating the liquid therein is in open communication with a regulating vat. The liquid displaced from the absorption vat by the gas flows into the regulating vat, wherein it is measured and whence it flows back to the absorption vat at a rate dependent on the speed with which the gas is absorbed. The gas is led into the absorption vat at the part which is on top when the vat is at rest.—J. H. P.

Carboy hampers or crates. A. W. Cowburn, and W. H. Cowburn and Cowpar, Ltd., Manchester. Eng. Pat. 113,930, Oct. 31, 1917. (Appl. No. 15,866 of 1917.)

[*Nickel*] *catalytic agent.* A. Mittasch, C. Schneider, and H. Morawitz, Assignors to Badische Anilin u. Soda Fabr., Ludwigshafen, Germany. U.S. Pat. 1,256,032, Feb. 12, 1918. Date of appl. June 4, 1914.

SEE Eng. Pat. 8462 of 1914; this J., 1915, 822.

Metal heating, metallurgical and analogous heating furnaces. Eng. Pat. 113,594. See X.

Uninflammable liquids for use in insulating and other similar purposes. U.S. Pat. 1,255,618. See XI.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Effect of low-temperature oxidation on the hydrogen in — and the change in weight of coal on drying. S. H. Katz and H. C. Porter. Techn. Paper No. 98, U.S. Bureau of Mines. [15 pages.]

MOST of the work of previous investigators of the oxidation of coal as related to the hydrogen of the coal substance was at the temperature of boiling water and above. The results varied widely, probably due to the absorption of gas by the coal on drying. Mahler has given trustworthy data showing that in low-temperature oxidation hydrogen is evolved from coal in the form of water (see this J., 1910, 744, 868). In the apparatus used by the authors, nitrogen or air passed from a drying train through a large quantity of coal at room temperature, thence through another drying train which caught the water given up by the coal. The weight of water and the change of weight of the coal were then ascertained. When nitrogen was passed through the coal there was invariably a loss in weight, much less, however, than the weight of water evolved from the coal. The small amount of oxygen in the nitrogen is not sufficient to account for the discrepancy, which may be due to absorption of nitrogen by the coal. When air was passed through there was always a gain in weight despite the loss of water. Analyses of the coal before and after the experiments showed an increase in oxygen content and a corresponding decrease in other constituents, but no loss of hydrogen could be shown by these analyses. No evidence is afforded that water is produced by the oxidation of coal at ordinary temperatures.

—J. E. C.

Gas; Effect of the removal of light oils from —. L. J. Willien. Amer. Gas Inst., 1917. Gas J., 1918, 141, 442—443.

LIGHT oils may be removed from coal gas by scrubbing, compression, or cooling. The average yield is about 3 gallons per ton of coal carbonised, the following being the approximate composition: benzol, 50 to 60%; toluol, 12 to 13%; solvent naphtha, 10 to 12%; heavy naphtha and wash oil, 13%. The author gives tables showing the effects of removing light oils from coke-oven gas, coal gas, carburetted water-gas, and mixed gas, and the following conclusions are drawn:—The candle power is materially reduced (up to 50% with fairly complete removal). The heating value is reduced from 1.5 to 8%. The naphthalene content is reduced about 75% if the gas is scrubbed with a naphthalene-free oil, whilst partial scrubbing is liable to increase naphthalene stoppages. From

30 to 50% of the carbon bisulphide is removed. There is less accumulation of drip-oil in the distribution system; the gas is more permanent; the scrubbed gas is in better condition for re-enrichment, and the gas is more uniform and less liable to cause stoppage in the service pipes.

—J. E. C.

Natural gas and its constituents; Compressibility of — with analyses of natural gas from 31 cities in the United States. G. A. Burrell and I. W. Robertson. U.S. Bureau of Mines, Techn. Paper 158, 1917. Petroleum Technology No. 32. [16 pages.]

THE apparatus used for determining the compressibility of gases consisted of three water-jacketed capillary tubes, the upper ends of which were sealed, the lower ends passing through stuffing-boxes into a steel compression machine containing mercury. By means of a plunger, the mercury could be forced into the glass capillary tubes, thereby compressing the gases contained therein to any desired degree. One tube contained the gas under examination; the other two contained air and served as pressure gauges, the pressure-volume curve for air having been previously determined (Burrell and Robertson, Techn. Paper 131; this J., 1916, 955). The compressibility of pure methane, ethane, propane, and carbon dioxide and of samples of natural gas from a number of cities in the United States was determined and curves were constructed showing the percentage deviation from a perfect gas at pressures varying from 0 to over 40 atmos. The deviations per atmos. for the pure gases were found to be: CH_4 , 0.228%; C_2H_6 , 0.90%; C_3H_8 , 1.9%; CO_2 , 0.67%. To illustrate the method of calculating the compressibility of any natural gas, the following example is given: The natural gas used in Buffalo is composed of 88.1% CH_4 , 11.5% C_2H_6 , and 0.4% N_2 . The partial pressures of the three constituents at 40 atmospheres are: $\text{CH}_4 = 0.881 \times 40 = 35.2 = P_1$; $\text{C}_2\text{H}_6 = 0.115 \times 40 = 4.6 = P_2$; $\text{N}_2 = 0.004 \times 40 = 0.2 = P_3$. The formula for total deviation is, $D = aP_1 + bP_2 + cP_3 + dP_4 + \dots$, where a, b, c, d, etc., are the deviations per atmos. for the constituents. Substituting values in the formula, $D = (0.228 \times 35.2) + (0.90 \times 4.6) = 8.03 + 4.14 = 12.17\%$, or the compressibility at 40 atmospheres is 87.83 on the basis of that of an ideal gas being 100. This method gives results closely in accordance with actual determinations and can be applied to calculate the compressibility of any natural gas, provided an ordinary analysis has been made.

—L. A. C.

Tar; Water in gas —. M. Coudelou. J. Usines à Gaz. Gas. J., 1918, 141, 201.

IN order to reduce the percentage of water in tar delivered to distillers, the following means have been adopted. In place of the plentiful supply of ammoniacal liquor kept in the hydraulic main to form a hydraulic seal, and introduced under the surface of the tar, only a thin stream of clean water is admitted. The reservoir used to form a hydraulic seal in the passage of the tar from the hydraulic main to the works' tank, which helped to form an emulsion of the tar and water, has been replaced by a vertical length of pipe leading into the tank, the tar entering the tank along an inclined plane, down which it flows in a thin layer from which globules of water easily separate. A similar arrangement is used for filling the wrought-iron cylindrical vessel used for pumping the tar from the works' to the storage tank, in place of the single pipe used before both for filling and emptying the vessel. By the above means, the percentage of water in the tar has been reduced from 15—30% to an average of 5%.—L. A. C.

Petrol; [Determination of] calorific value of —.
B. Blount. Analyst, 1918, 43, 89.

THE bomb calorimeter method is preferable for determining the calorific value of petrol, but it is necessary to enclose the petrol in a combustible envelope the calorific value of which is known; collodion may be used for the purpose.—W. P. S.

Petrol: Determination of sulphur in —. B. Blount. Analyst, 1918, 43, 89.

THE Carius method is the most reliable for the purpose. Burning the petrol under a tower down which a solution of ammonia and ammonium carbonate trickles is untrustworthy, as only a portion of the sulphur is retained. The use of a calorimeter bomb rarely gives good results. The sulphur in petrol cannot be oxidised by heating with concentrated nitric acid under a reflux condenser. The quantity of sulphur in petrol is usually less than 0.10%.—W. P. S.

PATENTS.

Pulverised fuel and air feeder and mixer. G. W. Clendon, N.Y., Assignor to Locomotive Pulverized Fuel Co. U.S. Pat. 1,254,393, Jan. 22, 1918. Date of appl., July 17, 1914.

AN air conduit with an annular orifice discharges a hollow column of air into a mixing chamber. Pulverised fuel is conveyed through this hollow column by a screw conveyor and the air and fuel are mixed by a series of non-retarding rotating vanes in the mixing chamber.—J. E. C.

Coke oven. P. Plantinga, Cleveland, Ohio. U.S. Pat. 1,255,047, Jan. 29, 1918. Date of appl., July 26, 1916.

AN inclined coking chamber is combined with a set of parallel combustion chambers arranged one above the other and adjacent to one side of the coking chamber.—J. E. C.

Coke-oven. F. A. Bredel and J. Bergmann, St. Louis, Mo. U.S. Pat. 1,255,579, Feb. 5, 1918. Date of appl., Aug. 22, 1916.

A COKE-OVEN consists of an inclined coal chamber, the bottom wall being straight and the top wall being provided with an offset between the upper and lower ends of the chamber. The gas outlet is in the offset portion.—J. E. C.

Gaseous fuel; Process of manufacturing —. J. R. Rose, Edgeworth, Pa. U.S. Pat. 1,254,360, Jan. 22, 1918. Date of appl., May 19, 1916.

METHANE is supplied to one end of an elongated line filled with refractory material and heated to at least 2200° F. (1200° C.). A preheated liquid hydrocarbon is supplied to an intermediate portion, and the mixture is dissociated giving a gas of high heating efficiency and of low carbon content.—J. E. C.

Gas-producer. E. A. W. Jefferies, Assignor to Morgan Construction Co., Worcester, Mass. U.S. Pat. 1,255,015, Jan. 29, 1918. Date of appl., Dec. 14, 1914.

THE fuel receptacle of the producer is supported by the ash-pan and rotates therewith, the supporting means being so arranged that the surface of the ash-pan from the centre to the periphery and the annular spaces between the wall of the fuel receptacle and the wall and bottom of the ash-pan are entirely unobstructed.

Gas-cleaner. J. Ruddiman, Hastings-upon-Hudson, N.Y. U.S. Pat. 1,254,438, Jan. 22, 1918. Date of appl., Apr. 25, 1917.

A GAS cleaner comprises a chamber, with means for maintaining a supply of wash water in the lower portion, a gas inlet and outlet, and a pair of rotary perforated baffles dipping in the wash water and interposed between the inlet and outlet. The gases passing through the perforations of one plate are directed by nozzles against the inter-spaces between the perforations of the adjoining baffle.—J. E. C.

Gas burners. Fletcher, Russell and Co., Ltd., T. W. Fletcher, and W. Banks, Warrington. Eng. Pat. 113,355, Mar. 27, 1917. (Appl. No. 4413 of 1917.

IN a gas furnace burner, a single removable and renewable nozzle is fitted on the top of an enlarged rectangular box-shaped chamber connected to the mixing tube. The nozzle may be open at its lower end, or closed and provided with slits or saw-cuts, whilst sliding plates are provided for regulating the opening to the passage of the mixture chamber.—J. E. C.

Oils and gases; Process and apparatus for separation of —. P. Jones, Santa Maria, Cal. U.S. Pat. 1,255,018, Jan. 29, 1918. Date of appl., Mar. 30, 1916.

A MIXTURE of oil and gas flowing from a well under pressure is introduced into a receiving chamber and maintained under pressure. The oil separates by gravity and passes away through a restricted outlet, whilst the gas passes away, by an outlet controlled by a valve, at a rate which is varied according to the rate of separation of the oil, so as to maintain the gas under pressure.—J. E. C.

Petroleum; Treatment and refining of —. R. Cross, Kansas City, Mo. U.S. Pat. 1,255,138, Feb. 5, 1918. Date of appl., Jan. 8, 1917.

HEAVY petroleum hydrocarbons are heated to a temperature not exceeding 450° C., and the vapours led over a body of the same material in a tank, which serves as a supply tank, on their way to a condenser. A pressure is maintained over both bodies of liquid which is equal to or greater than the normal vapour pressure of the gases in equilibrium with the liquid phase at the temperature of the oil at the entrance to the condenser. Oil is fed to the supply tank at a rate corresponding to the combined withdrawal of vapour from the supply tank and of residual oil from the still.

—L. A. C.

Hydrocarbon oils; Apparatus for vaporising —. C. B. Forward, Urbana, Ohio. U.S. Pat. 1,255,149, Feb. 5, 1918. Date of appl., Feb. 5, 1916.

A NUMBER of horizontal retorts of different elevations are contained in a furnace chamber, each consisting of an inner tube for oil and an outer tube for steam. The inner tubes extend beyond the furnace walls and are connected one with the other; the outer tubes terminate at the walls. Packing is provided between the ends of the two tubes; the inner tube is free to slide in the packing and the corresponding end of the outer tube is supported on rollers to allow for uneven expansion. The pipes from the jackets of the retort sections discharge into the jacket of a tubular steam-jacketed oil heater, the oil and steam from which pass into the corresponding parts of the upper retort sections.—L. A. C.

Pressure-still [for producing light oils from gas oils]. J. J. Curran, Augusta, Kans. U.S. Pat. 1,255,714, Feb. 5, 1918. Date of appl., May 25, 1917.

A BATTERY of stills with a common feed pipe discharge through individual valved pipes into a

common drum in which light and heavy distillates are separated. Connected with the drum is a condenser for light hydrocarbon vapours. The heavy distillate passes by gravity from the drum to a separate still which is connected by a valved pipe to the same condenser. Steam is passed into all the stills.—L. A. C.

[Gaseous] fuel: Apparatus for producing combustible —. J. R. Rose, Edgeworth, Pa., U.S.A. Eng. Pat. 113,585, Feb. 28, 1917. (Appl. No. 16,126 of 1917.)

Distilling [carbonaceous matter]: Apparatus for —. W. P. Perry, South Woodford, Essex. Eng. Pat. 113,373, May 1, 1917. (Appl. No. 6140 of 1917.)

CARBONACEOUS material is distilled in a suitable vessel, the non-volatile portion being burnt in the lower section, giving off gas, which rises through the upper layers and drives off the volatile matter. This is collected by a series of pipes arranged at varying heights across and within the vessel, and having slots with upturned lips or conical openings on the underside. The slots or openings are at the centre of the vessel.—J. E. C.

Distilling combustible materials. C. Foxwell, Baltimore, Md. U.S. Pat. 1,255,593, Feb. 5, 1918. Date of appl., Feb. 23, 1917.

IN order to recover benzol and ammonia, combustible materials are treated with a solution of calcium chloride and borax and then distilled in a by-product oven.—J. E. C.

Vapour electric device [lamp]. D. McF. Moore, East Orange, N.J., Assignor to General Electric Co. U.S. Pat. 1,255,549, Feb. 5, 1918. Date of appl., June 16, 1915.

A GASEOUS conduction device, such as a gas electric lamp, comprises a tubular receptacle containing a column of rarefied gas, electrodes within the receptacle, and a source of constant current connected to the electrodes to produce an electrical luminous discharge through the rarefied gas. A material, which evolves gas when heated, is contained in a second receptacle, in communication with the first one but removed from the path of the discharge, and a heating coil, in a closed circuit arranged as a shunt to the main circuit, is embedded in the material evolving gas. The resistance of this shunt circuit is so adjusted that the current flowing therein will vary in such a way as to keep the density of the gas in the receptacle substantially constant.—B. N.

III.—TAR AND TAR PRODUCTS.

Crude benzols; Comparative values of coke-oven —. B. W. Haigh and H. Lamb. Coke-Oven Managers' Assoc. Gas J., 1918, 141, 201–203.

THE authors have investigated the retort test for

crude benzol and have endeavoured to devise a satisfactory method whereby in working up low-grade crude benzols, the results may be expressed on the standard 65% basis. A series of samples were submitted to two methods of distillation. In the first, the apparatus consisted of a 250 c.c. retort with a shortened neck fitted into a Liebig condenser. The thermometer was graduated in half degrees from 90° to 200° C., the bulb being $\frac{3}{8}$ in. from the bottom of the retort. Corrections for barometric pressure and exposed stem were applied to all readings, the latter being obtained from the formula $C=0.000154(T-t)N$, where T and t are respectively the observed temperature and the mean temperature of the exposed stem and N is the number of degrees in the exposed column. The rate of distillation was two drops per second and the interruption points 120° C. and 160° C. In the second method the retort was replaced by a 150 c.c. distillation flask, the bulb of the thermometer being placed just below the side tube. The thermometer was graduated to $\frac{1}{2}^{\circ}$ from 70° to 130° C. The interruption points were 84°, 90°, 100°, 120°, and 130° C. The results showed that the retort test is trustworthy if carried out under uniform conditions and corrections applied to the thermometer readings; however, it has limitations in that it fails to show in what respect a particular benzol is abnormal and gives little insight into the relative proportions of benzene, toluene, and xylene in the sample. The flask test should therefore be adopted generally as supplementary to the retort test. For comparing crude benzole, samples were fractionally distilled to 200° C., using a Young's rod and disc column with twenty discs, the residue being a creosote oil of b.pt. about 205° C., and having a high naphthalene content. The residue was found to be larger the poorer the quality of the benzol, and from the results obtained, a graph was drawn whereby the values of low-grade benzols in terms of normal 65% benzol could be calculated for the particular plant from which the samples were obtained. Sufficient samples were not available from other works to draw any conclusions as to variations in quality of the products of other plants.—L. A. C.

Trichlorobenzenes; The three — and their reaction with sodium methoxide. A. F. Holleman. Rec. Trav. Chim. Pays-Bas, 1918, 37, 195–204.

THE three trichlorobenzenes when heated with sodium methoxide in a sealed tube at 180° C. reacted as follows:—1,2,3-trichlorobenzene gave 2,3- and 2,6-dichlorophenols with the corresponding anisols; 1,2,5-trichlorobenzene gave 2,5-dichlorophenol and a little 2,5-dichloroanisole; 1,3,5-trichlorobenzene yielded 3,5-dichloroanisole and a little 3,5-dichlorophenol. (See also J. Chem. Soc., May, 1918.)—W. G.

Nitro compounds; Reaction of aromatic —. S. C. J. Olivier. Rec. Trav. Chim. Pays-Bas, 1918, 37, 241–244.

THE twelve aromatic nitro compounds examined all gave an orange-red coloration with aluminium bromide in benzene solution, the colour disappearing on the addition of water. In the absence of a solvent, or on replacing the benzene by carbon bisulphide, the colour reaction was not obtained in most cases. (See also J. Chem. Soc., May, 1918.)—W. G.

Bromination of *p*-nitrotoluene. J. F. Brewster. J. Amer. Chem. Soc., 1918, 40, 406–407.

p-NITROBENZYL bromide, a useful agent for characterising phenols and carboxylic acids, is prepared by adding bromine gradually to a boiling solution of *p*-nitrotoluene in carbon tetrachloride, containing a crystal of iodine and exposed to sunlight.—J. C. W.

Tolane chlorides from calcium carbide, chlorine, and benzene. C. Davidson. J. Amer. Chem. Soc., 1918, 40, 397—400.

By adding calcium carbide, free from iron, to a saturated solution of chlorine in benzene, tolane di- and tetra-chlorides have been obtained. It is supposed that the primary dichloroacetylene condenses with benzene to form tolane, thus: $\text{CCl} : \text{CCl} + 2\text{C}_6\text{H}_6 \rightarrow \text{C}_6\text{H}_5\text{C} : \text{C} \cdot \text{C}_6\text{H}_5 + 2\text{HCl}$. (See also J. Chem. Soc., May, 1918.)—J. C. W.

PATENTS.

Benzol; Process of purifying crude —. H. B. Kipper, Muskegon, Mich. U.S. Pat. 1,253,048, Jan. 8, 1918. Date of appl., Apr. 27, 1917.

CRUDE benzol is purified from carbon bisulphide by treatment in a finely divided form with a counter-current of a solution containing caustic soda and cellulose.—F. W. A.

[*Dimethylphenylbenzyl ammonium zinc chloride; Dimethylaniline, benzyl chloride, and zinc chloride; Manufacture of a difficultly soluble complex compound from* —. F. B. Dehn, London. From Chemical Works Rohner & Co., Pratteln, Switzerland. Eng. Pat. 104,676, Feb. 7, 1917. (Appl. No. 1905 of 1917.)

BENZYL chloride and dimethylaniline in molecular proportions are mixed with an aqueous solution of zinc chloride containing a slight excess above half a molecular proportion of zinc chloride; after prolonged stirring the separation of the difficultly soluble crystals of the double compound of zinc chloride and dimethylphenylbenzyl ammonium chloride is complete. (Reference is directed in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pat. 24,695 of 1914; this J., 1916, 248.)—F. W. A.

β -Naphthol benzoate; Process of making —. G. Bieberger, Assignor to Anthony-Hammond Chemical Works, Inc., New York. U.S. Pat. 1,251,970, Jan. 29, 1918. Date of appl., Dec. 5, 1916.

To produce β -naphthyl benzoate, benzoyl chloride is allowed to drop on to 110 grms. of heated β -naphthol with stirring until about 170 grms. has been added, any evaporated benzoyl chloride being condensed and returned, and the hydrogen chloride allowed to escape.—F. W. A.

Beta aminoanthraquinone; Process for the manufacture of —. P. Dutoit, Monthey, Assignor to Soc. of Chem. Ind. in Basle, Switzerland. U.S. Pat. 1,255,719, Feb. 5, 1918. Date of appl., Apr. 26, 1917.

β -ANTHRAQUINONEMONOSULPHONIC acid is heated with ammonia and an aromatic nitro-compound, yielding β -aminoanthraquinone and an aromatic amino-compound.—L. A. C.

IV.—COLOURING MATTERS AND DYES.

1,4,6-Trihydroxyanthraquinone. M. L. Crossley. J. Amer. Chem. Soc., 1918, 40, 401—406.

WHEN 4-aminophthalic anhydride is heated with quinol and concentrated sulphuric acid at 170°—190° C., the chief product is 1,4,6-trihydroxyanthraquinone. This has no particular value as a mordant dye. (See also J. Chem. Soc., May, 1918.)—J. C. W.

Phthalic acid derivatives. Constitution and colour. XII. Tetrachlorophthaloxime and some of its derivatives. D. S. Pratt and C. H. Miller. XIII. Tetra-iodophthaloxime and some of its derivatives. D. S. Pratt and T. B. Downey. J. Amer. Chem. Soc., 1918, 40, 407—412, 412—415.

THE oximes mentioned are prepared by the action of hydroxylamine salts on the substituted phthalic anhydrides in the presence of alkali carbonates, and their ethers and esters through their silver salts. They differ from unsubstituted phthaloxime in occurring in only one colour, this forming two chromo-isomerides. Some of the tetrachlorophthaloxime ethers, $\text{C}_6\text{Cl}_4 \langle \text{CO} \text{---} \text{C}(\text{N} \cdot \text{OR}) \rangle \text{O}$

are unique in existing in two interchangeable crystalline forms, cotton-like masses, and stable, stout prisms. (See also J. Chem. Soc., May, 1918.)

—J. C. W.

PATENTS.

Azo dyestuffs; Manufacture of new copper compounds of substantive —. O. Inray, London. From Soc. of Chem. Ind. in Basle, Switzerland. Eng. Pat. 113,141, Feb. 8, 1917. (Appl. No. 1950 of 1917.)

A SOLUTION of a direct azo dyestuff obtained by combining 1 mol. of a tetrazo compound of a *para*-diamine derived from the diphenyl nucleus and having in *ortho*-position to an amino group at least one alkyloxy group, with 1 mol. of 2-amino-5-naphthol-7-sulphonic acid or an alkyl, aryl, or acetyl derivative and 1 mol. of a 1,8-amino-naphtholsulphonic acid or a derivative thereof, or with 2 mols. of 2-amino-5-naphthol-7-sulphonic acid or a derivative thereof, is treated with copper or a copper compound, and the soluble copper compound of the dyestuff is isolated. In addition to dyeing cotton direct shades which, without any after-treatment, are of excellent fastness to light, alkali, and washing, the new copper compounds dye like substantive dyestuffs, wool, silk, mixed fabrics, straw, wood, paper, leather, and the like, and may, moreover, be used in printing and for making lakes fast to light.—F. W. A.

[*Azo*] *colouring matter; Manufacture of a* —. E. F. and H. W. Ehrhardt, Birmingham. Eng. Pat. 113,181, Apr. 5, 1917. (Appl. No. 4939 of 1917.)

DIAZOTISED picramic acid is combined with pure *p*-cresol or with the solution resulting from the fractional combination of diazotised picramic acid with a mixture of cresols, when the *o*-cresol couples first to give Metachrome Brown Y. The new *ortho*-azo dyestuff gives a chocolate-brown shade on unmordanted wool, and on chrome mordant gives an olive-brown shade, fast to milling and to light.—F. W. A.

Disazo colouring matter; Production of a mixed —. E. F. and H. W. Ehrhardt, Birmingham. Eng. Pat. 113,195, Apr. 30, 1917. (Appl. No. 6117 of 1917.)

DIAZOTISED *p*-phenylenediamine-azo-salicylic acid is combined with β -naphthylamine free from impurities soluble in or destroyed by caustic soda. The product is insoluble in water, but if ground to a uniform gelatinous mass forms a colloidal solution which may be used for dyeing unmordanted cotton pink to red shades or for dyeing wool by the metachrome process bright red shades.

—F. W. A.

N-Dihydro-1,2,2',1'-anthraquinoneazine [Indanthrene]; *Manufacture of* —. British Dyes, Ltd., J. Turner, and D. Segaller, Huddersfield. Eng. Pat. 113,489, Feb. 26, 1917. (Appl. No. 2776 of 1917.)

CRUDE N-dihydro-1,2,2',1'-anthraquinoneazine

(Indanthrene) is treated with oxidising agents (of which the following salts are suitable: sodium, potassium, calcium, strontium, and barium salts of hypochlorous, chloric, permanganic, and persulphuric acids) in aqueous solution and in such proportion and concentration that the yellow colouring matter present as an impurity is oxidised, the Indanthrene itself not being attacked. For example, one part by weight of crude 10% N-dihydro-1,2,2',1'-anthraquinoneazine paste is boiled with four parts of sodium hypochlorite solution (sp. gr. 1.15) for six hours with vigorous stirring. After cooling, the blue dyestuff is filtered off and washed free from sodium hypochlorite.—L. A. C.

Yellow colouring matter [tetrachlorotartrazine]; Process for the production of—L. B. Holliday and A. Clayton, Huddersfield. Eng. Pat. 113,510, Mar. 7, 1917. (Appl. No. 3372 of 1917.)

Two mols. of 2,5-dichlorophenylhydrazine-1-sulphonic acid or its salts react with one mol. of dihydroxytartaric acid or its salts, in either acid or neutral medium, to give a colouring matter which dyes wool and silk an intense yellow, and is assumed to be identical with tetrachlorotartrazine of Eng. Pat. 3373 of 1908 (see Fr. Pat. 387,245 of 1908; this J., 1908, 801). Example: 518 lb. of 2,5-dichlorophenylhydrazine-1-sulphonic acid is intimately mixed with 1500 lb. of water containing 80 lb. of sodium hydroxide. 190 lb. of sodium dihydroxytartrate is dissolved in a mixture of 300 lb. of water and 380 lb. of hydrochloric acid (sp. gr. 1.16). The first solution is added slowly to the second and the two thoroughly mixed. The temperature is then raised to about 80° C., and maintained at that point for half an hour or more. The dyestuff settles out and is filtered off.—L. A. C.

Vegetable dye, and method of preparing same. I. Kitsee, Philadelphia, Pa. U.S. Pat. 1,251,914, Jan. 29, 1918. Date of appl., Nov. 26, 1915.

Fast dyes are produced from a "vegetable base" by addition of zinc chloride and ammonium copper chloride.—F. W. A.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

PATENTS.

Fireproof composition [for fabrics]. J. Truro, Redditch. Eng. Pat. 113,162, Mar. 5, 1917. (Appl. No. 3195 of 1917.)

A FIREPROOF composition consists of substantially 25% of ammonium phosphate, 50% of ammonium chloride, and 25% of alum made up in liquid, powder, or tablet form, vinegar being added in case the solution is to be applied to fabric, to prevent it from affecting the dye.—F. W. A.

Cellulose; Digesters for use in the manufacture of—and like operations. E. Schaufelberger, London. Eng. Pat. 113,191, Feb. 28, 1917. (Appl. No. 2982 of 1917.)

A CELLULOSE digester is constructed with an external system comprising a heater, a circulating device, and one or more separators to purify the liquid during circulation. In the case of a vertical digester the liquid is preferably caused to enter at the bottom and is forced upwards through the material. An arrangement may be provided in the form of a float attached to a flexible connection, whereby the outlet pipe at the top of the digester descends as the level of the liquid falls during the course of the digestion. The separator may consist of a vessel into which the liquid enters through the bottom by way of a projecting bell-mouthed orifice, which reduces the velocity

of the flow, whereby the floating impurities are collected in the upper part of the vessel while the heavy impurities settle at the bottom and the liquid passes on into the circulating system through a strainer situated in the vessel.—J. F. B.

Paper-makers' [mechanical] pulp; Manufacture of—W. Fennell, Wotton, S. D. Lane and W. O. Garbutt, Gloucester. Eng. Pat. 113,621, July 15, 1916. (Appl. No. 9963 of 1916.)

Dryer [for fibrous materials]. U.S. Pat. 1,251,073. See I.

Machine for impregnating fabrics with rubber. U.S. Pat. 1,255,192. See XIV.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Cotton yarn; Experiments on the mercerisation of—by caustic soda lye. T. Nakata, Kōgyō-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1917, 20, 1224—1231.

TWO-PLY 60's cotton yarn was boiled out in dilute caustic soda and soap solution and portions were mercerised without previous drying. Samples from which the mercerising soda was merely removed by squeezing had only 66% of the tensile strength of samples similarly treated and thoroughly purified by washing and drying. When moist yarn was mercerised in caustic soda of 53° Tw. (sp. gr. 1.265) without tension at 25° C., maximum shrinkage (18.61%) was recorded in the case of yarn containing 75% of additional moisture calculated on the weight of the dry, boiled yarn. Under these conditions of moisture the mercerisation process exerts its maximum effect. The strength and elongation of mercerised yarns are important factors in their textile value. These depend largely on the amount of stretching to which the yarn is subjected during mercerisation. The elongation of the finished yarn in tensile tests increases largely with the shrinkage allowed and decreases if the mercerised yarn is stretched beyond its original dimensions. No definite rule can be stated as the results are greatly influenced by the count and ply of the yarn. A 2-ply 60's yarn with an original hank-circumference of 54 ins., and 52.44 ins. after boiling, can be mercerised under tension at 30° C. in a lye of 50° Tw. (sp. gr. 1.25) so as to give a length of 51—51.5 ins. without loss of elasticity and with an increase of about 20% in tensile strength as compared with the original.—J. F. B.

PATENTS.

Bleaching and like treatment of cotton, cotton waste, wool, and similar materials; Means for circulating bleaching and other liquors in the—T. Taylor, Stockport. Eng. Pat. 112,969, June 26, 1917. (Appl. No. 1323 of 1917.)

IN the steam ejector employed, additional steam is admitted into the delivery nozzle to heat the induced fluid, giving simultaneous circulation and heating of the bleaching or other liquor. (Reference is directed, in pursuance of Sect. 7 Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 2869 of 1883, 15,174 of 1893, and 5744 of 1915.)—F. W. A.

Textile fibres; Machines for dyeing and finishing—F. F. Larivei, Bradford. Eng. Pats. (A) 113,453 and (B) 113,451, June 7, 1916. (Appl. Nos. 8050 and 8051 of 1916.)

(A) A MACHINE adapted for experimental work is

constructed with rollers for supporting hanks or bunches of textile fibre over a dye vessel or vat which is divided into a number of separate and independent casings each corresponding to a particular roller. The whole vat is mounted on gear to be lifted or lowered relatively to the rollers, or the rollers may be moved relatively to the vat. Each separate chamber of the vat has its own independent inlet and outlet and separately adjustable heating arrangement, and means may be provided whereby the speed of the rollers may be adjusted independently of each other. (B) A machine of the same general type as the foregoing is constructed with two or more vats which can be controlled independently, each provided with several rollers which may be driven either independently or together.—J. F. B.

[Aniline] *Black upon vegetable fibres; Production of* —. The Calico Printers' Association, Ltd., and E. A. Fourneaux, Manchester. Eng. Pat. 113,484, Feb. 28, 1917. (Appl. No. 2610 of 1917.)

THE process described in Eng. Pat. 7345 of 1908 (this J., 1909, 701) is modified in that the use of aluminium chloride is discontinued and the proportion of *p*-phenylenediamine is reduced to $\frac{2}{5}$ — $\frac{1}{6}$ of the weight of aniline employed. The presence of a certain amount of formic acid is necessary. When organic acids only are used, the proportion of formic acid should not be less than 2 mols. and may be as high as 4 mols. per mol. of aniline. The organic acids may be partly replaced by mineral acids to an extent not exceeding 0.3 mol. per mol. of aniline. When mineral acids are employed as well as organic acids, the proportion of formic acid should not fall below 1 mol. and may be as high as 2.5 mols. per mol. of aniline. The formic acid may be replaced by acetic, lactic, or glycollic acid to an extent not exceeding one-fifth. When organic acids only are used, formic acid should be employed in conjunction with tartaric acid. The proportion of copper salt employed should be between $\frac{1}{5}$ and $\frac{1}{8}$ mol. per mol. of aniline. Example: Aniline oil, 63.5; 90% formic acid, 125; tartaric acid, 18.25; *p*-phenylenediamine dihydrochloride, 5.5; sodium chloride, 33.75; copper chloride, 13, made up to 1000 parts by weight. The copper chloride is added immediately before use.—J. F. B.

Yarns in the form of hanks, skeins, or bundles; Method of and machines for dyeing or similarly treating —. J. Annick, Manchester. Eng. Pat. 113,575, Aug. 31, 1917. (Appl. No. 12,511 of 1917.)

THE dry yarn is packed into a rectangular tank with perforated side walls and perforated central chamber, the threads being laid horizontally in approximately the same direction as the flow of the liquor; pressure is then applied, *e.g.*, not less than 20 lb. per sq. in., sufficient to expel as far as possible the air from the packed bundles before the liquid is introduced, such pressure being controllable by the amount of dry yarn packed into the tank, which is fitted with extension plates, and by means of suitable pressure devices applied to the lid before it is screwed down. For instance, the yarn is piled horizontally in the vat to a height which is above the normal position of the lid. The lid is placed on the top of the pile and is guided by extension plates held in position between the packed yarn and the ends of the tank and passing through slots in the lid. The lid is forced down by screw clamps, compressing the yarn, until it can be bolted down; the extension plates are then removed and the slots covered, and liquor is circulated through the perforated sides of the chambers by means of a pump.—J. F. B.

Fibres; Process and apparatus for treating —. H. R. Anders, Perth Amboy, N.Y., Assignor to The Roessler and Hasslacher Chemical Co., New York. U.S. Pat. 1,252,986, Jan. 8, 1918. Date of appl., Dec. 21, 1914.

A ROTARY container with encased heating means near the centre is divided by partitions into a number of chambers preferably of substantially equal size, connected by a channel encasing the heating means, in order to heat the liquid. The chambers are completely packed with the fibres wetted-out with the liquid with which they are to be treated. Only one of the chambers is filled with liquid, which passes through the chambers in diagonally opposite directions and is filtered consecutively through the goods in each chamber when the container is rotated.—F. W. A.

Dyeing apparatus. D. M. Hey, Assignor to Vacuum Dyeing Machine Co., Chattanooga, Tenn. U.S. Pat. 1,254,006, Jan. 15, 1918. Date of appl., Dec. 13, 1915.

A DYEING apparatus consists of a vat connected at its lower portion and at the top (by a spray head above the dye liquor) with the discharge side of a pump which is connected at the suction side by means of an elbow-jointed pipe (with air-inlet in elbow) to a heating chamber into which passes the overflow from the vat. Valves are arranged so that when in one position the dye liquor circulates through the heating chamber, entering the lower part of the vat and leaving at the upper part, and when in another position the circulating path does not include the heating chamber, the liquor leaving the lower portion of the vat and entering through the spray head in the upper portion.—F. W. A.

Printing fibrous substances; Machine for —. A. Amrein, Amsterdam, N.Y. U.S. Pat. 1,252,985, Jan. 8, 1918. Date of appl., May 9, 1917.

THE face of a rotary printing drum is made up of a series of platen and pattern index faces, index tongues of determined colour values being arranged on the index faces in accordance with a predetermined pattern. The printing rolls are engaged by the index tongues of corresponding colour values, and have their axes in constant spaced relation with the axis of the printing drum. Means are provided for transferring colour to the printing rolls, and for rendering certain of the indexes inoperative to actuate predetermined printing rolls.—F. W. A.

Printing fabrics; Process of —. G. Prifold, Linwood, Pa., Assignor to The Congoleum Co., Philadelphia, Pa. U.S. Pat. 1,255,049, Jan. 29, 1918. Date of appl., Apr. 24, 1917.

WOVEN fabrics are printed with a mixture of an aniline colour capable of dyeing the fabric and a starchy vehicle capable of being dried and dusted out of the fabric, and are then steamed to cause the colouring matter to enter the body of the fabric, dried, brushed to remove the vehicle from the coloured fabric, and finally sized on the back.

—F. W. A.

Manufacture of a difficultly soluble complex compound [dimethylphenylbenzylammonium zinc chloride] from dimethylaniline, benzyl chloride, and zinc chloride. Eng. Pat. 104,676. See III.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphur in pyrites; Determination of —. Z. Karaoglanow, and P. and M. Dimitrow. Z. anal. Chem., 1917, 56, 561—568.

ABOUT 0.5 gm. of the finely powdered sample is oxidised with nitric and hydrochloric acids, or is

fused with a mixture of sodium carbonate and potassium nitrate, and after separation of silica in the usual way, the sulphuric acid is precipitated directly from the hydrochloric acid solution without previously removing the iron. The solution, which should contain from 30 to 50 c.c. of 6*N* hydrochloric acid, is diluted to 700 c.c., heated to boiling, and 40 c.c. of 10% barium chloride solution diluted with 100 c.c. of boiling water is added slowly while the mixture is stirred. After 15 hours, the barium sulphate is collected, washed with water containing hydrochloric acid and barium chloride, then with hot water, dried, ignited, and weighed. Under these conditions, the presence of ferric chloride does not affect the accuracy of the results obtained.—W. P. S.

Chlorates and hypochlorites; Determination of —. E. Rupp. *Z. anal. Chem.*, 1917, 56, 580—586.

A SUITABLE quantity, e.g., 10 c.c. of a solution containing about 0.5% of potassium chlorate and calcium hypochlorite, is diluted to 100 c.c. in a large stoppered flask, 2 grms. of potassium iodide is added, the solution is acidified with dilute acetic acid and, after 5 mins., titrated with thiosulphate solution; this titration gives the amount of hypochlorite. Another portion of 10 c.c. of the solution is treated in a stoppered flask with 1 gm. of potassium bromide and 30 c.c. of concentrated hydrochloric acid; after 15 mins., 15.0 c.c. of 1% potassium iodide solution is added, the mixture is shaken, and titrated with thiosulphate solution. The difference between the two titrations is a measure of the amount of chlorate present.—W. P. S.

Hypobromite and bromate, or hypoiodite and iodate; Determination of — in mixtures. E. Rupp. *Z. anal. Chem.*, 1918, 57, 16—19.

THE solution containing a hypobromite and bromate, or a hypoiodite and iodate, is treated with hydrogen peroxide and sodium hydroxide solution, the reaction proceeding according to the equation: $\text{NaBrO} + \text{H}_2\text{O}_2 = \text{NaBr} + \text{H}_2\text{O} + \text{O}_2$. The excess of hydrogen peroxide is then destroyed by boiling the mixture, potassium iodide and sulphuric acid are added, and the liberated iodine is titrated with thiosulphate solution. Another portion of the original solution is treated directly with potassium iodide and sulphuric acid and then titrated with thiosulphate solution. The difference between the two titrations gives the quantity of hypobromite present, whilst the second titration gives the hypobromite and bromate together.—W. P. S.

Iodates; Determination of — in the presence of bromates. E. Rupp. *Z. anal. Chem.*, 1918, 57, 19—21.

BROMATES are converted gradually by dilute hydrochloric acid into hydrobromic acid and hypochlorous acid is formed at the same time, but iodates are not affected. An aliquot portion of a solution containing an iodate and bromate is treated with potassium iodide and sulphuric acid, and, after a few minutes, the mixture is titrated with thiosulphate solution; this gives a measure of the iodate and bromate together. Another portion of the solution is diluted to 50 c.c., treated with 20 c.c. of 12.5% hydrochloric acid, placed aside for 1 hour, 25 c.c. of 3% hydrogen peroxide and 15 c.c. of 15% sodium hydroxide solution are then added, the mixture is boiled for 10 mins., cooled, potassium iodide and sulphuric acid are added, and the liberated iodine is titrated with thiosulphate solution. The difference between the two titrations corresponds with the amount of bromate present.—W. P. S.

Sodium manganate; Manufacture of crude —. F. Wartenweiler. *J. Chem., Met., Min. Soc. S. Africa*, 1918, 18, 161—162.

ON account of the scarcity of permanganate, the manufacture of crude sodium manganate was attempted in a four-hearth muffled calcining-furnace used for roasting zinc-gold precipitate. One part of finely powdered ferruginous pyrolusite (Mn 40%) was heated for 2 hours to 650°—750° C. with 1.44 part of caustic soda; the product assayed 18.2% Na_2MnO_4 . By introducing the charge into the furnace heated to 450° C., slowly raising the heat to 560° C., and maintaining it for 8 hours, then cooling for 4 hours, and withdrawing the charge, the grade of the product rose to 28% Na_2MnO_4 . The latter method has been adopted for supplying the mines.—W. R. S.

Prussian blue; Retardation of the formation of — and other reactions in aluminium hydroxide sols. J. Reitschötter. *Kolloid Zeits.*, 1917, 21, 197—200.

THE reaction between potassium ferrocyanide and ferric chloride is greatly retarded if the ferrocyanide solution is added to a colloidal solution of aluminium hydroxide with the subsequent addition of the ferric chloride to the coagulated system. Similar retardation effects are obtained with other pairs of substances and experiments are described which seem to offer an explanation of the phenomenon. (See also *J. Chem. Soc.*, Apr., 1918.)—H. M. D.

Dolomite; Decalcification of —. J. W. Mellor. *Trans. Ceram. Soc.*, 1917—1918, 17, 119.

THERE is no difficulty in separating the two main components of dolomite by chemical processes, but these are too costly to enable the product to compete with native magnesite. Separation may possibly be effected by a process based on the difference in the densities of the two constituents after calcination at high temperatures, or on the greater inertness of the magnesite when the calcined mass is exposed to water. The separation of the lime by washing the calcined product with water was patented in 1907 by Auzies and Segollin (*Fr. Pat.* 374,216; this *J.*, 1907, 761).—A. B. S.

Antimony dioxide. J. von Szilagy. *Z. anal. Chem.*, 1918, 57, 23—28.

ANTIMONY dioxide may be obtained by heating the pentoxide at bright redness, or by oxidising antimony with concentrated nitric acid and heating the resulting oxide at dull redness. Antimony dioxide dissolves in a hydrochloric acid solution of potassium iodide, an equivalent quantity of iodine being liberated: $2\text{SbO}_2 + 6\text{HCl} + 2\text{HI} = 2\text{SbCl}_3 + 4\text{H}_2\text{O} + \text{I}_2$. The iodine may be separated by distillation, collected in potassium iodide solution, and titrated. Although metastannic acid does not liberate iodine under these conditions, the reaction is of little use for the determination of antimony in the presence of tin, owing to the interfering action of even small quantities of other metals usually present in antimony-tin alloys.—W. P. S.

Radioactive substances; Colloidal state of —. H. Zachs. *Kolloid Zeits.*, 1917, 21, 165—176.

SOLUTIONS of certain radioactive substances show the characteristic properties of colloids, and these properties have been examined in the case of radium A, B, and C in different solvents. (See also *J. Chem. Soc.*, Apr., 1918.)—H. M. D.

PATENTS.

Bleaching powder: Manufacture of —. Castner-Kellner Alkali Co., Ltd., London, and J. W. Moore, Runcorn. Eng. Pat. 113,457, Nov. 23, 1916. (Appl. No. 16,822 of 1916.)

A CONTINUOUS stream of lime is carried, by gravity, through an inclined, rotary cylinder about 80 ft. long and 20 ins. wide, against a counter-current of chlorine. The flow of gas is maintained, and leakage prevented, by means of suction applied at the upper end of the cylinder. —W. E. F. P.

Tungstates: Process of obtaining —. J. B. Ekeley and W. B. Stoddard, Boulder, Colo. U.S. Pat. 1,255,111, Feb. 5, 1918. Date of appl., June 28, 1916.

TUNGSTEN ores are ground and fused in a bath containing sodium chloride or other halide of an alkali metal, sodium carbonate or other alkali, and silica or sodium nitrate. —C. A. M.

Lime: Method of slaking —. Apparatus for hydrating lime. A. Zimmerman, Assignor to L. M. Palmer, Brooklyn, N.Y. U.S. Pats. 1,255,268 and 1,255,682, Feb. 5, 1918. Dates of appl., Aug. 18, 1916, and Feb. 12, 1915.

In a continuous process, quicklime and a large excess of water are fed into the uppermost of a series of horizontal, cylindrical, rotary containers, maintained at the proper slaking temperature by external heating. The mixture is caused to traverse each cylinder in turn against a counter-current of air, so that the product is completely dried before being discharged from the apparatus. —W. E. F. P.

Nitre-cake: Method of recovering from —, products useful in the arts. L. T. Sherwood, Connellsville, Pa. U.S. Pat. 1,255,174, Feb. 5, 1918. Date of appl., Feb. 8, 1917.

THE heat of combustion of sulphur is utilised to convert nitre-cake into normal sodium sulphate and sulphur trioxide. The former product is recovered as such, and the latter, with the sulphur gases, as sulphuric acid. —W. E. F. P.

Alumina: Purification of —. J. W. Hornsey, Summit, N.J., Assignor to Mineral Products Corporation, New York. U.S. Pat. 1,255,749, Feb. 5, 1918. Date of appl., Aug. 11, 1917.

IMPURE alumina, obtained by calcining alumina and leaching the product, is mixed with water to form a pulp which, after the addition of oil, is subjected to froth flotation; pure alumina is recovered from the froth. —W. E. F. P.

Phosphorus [from basic slag]: Manufacture of —. H. O. H. Wennam, Bishop's Castle, Salop. Eng. Pat. 113,584, Nov. 2, 1917. (Appl. No. 15,982 of 1917.)

MOLTEN basic slag is charged direct from a steel furnace into an electric furnace; carbon and silica are then added and the mixture heated. —W. E. F. P.

Method and apparatus for treating liquid [to produce colloidal tungstic oxide] for curative and therapeutic purposes. Eng. Pat. 113,505. See XX.

VIII.—GLASS; CERAMICS.

Silica bricks: Inversions in —. A. Scott. Trans. Ceram. Soc., 1917—1918, 17, 137—152.

SECTIONS of unused silica bricks and those made at the same time, but subsequently subjected in the crown and other parts of furnaces, to temperatures between 1000° C. and 1600° C., were examined by customary micro-petrological methods. In the kiln-fired condition and ready for use, silica bricks are composed of fragments of crystalline quartz cemented by a glass rich in calcium silicates. The greater part of the quartz is unaltered, but there has usually been some reaction between the bond and the smaller quartz grains, resulting in the formation of a glass and partial reprecipitation of silica as cristobalite. In no British bricks was there so much conversion into cristobalite and tridymite as found by Seaver (this J., 1915, 1209) in American bricks. Bricks which have been used, even in the cooler parts of a furnace, show much more conversion. The silica of the matrix is usually converted completely to a little cristobalite and much tridymite; some of the quartz is converted, but the centres of the fragments remained unaltered. The alteration is greatest in those fragments which are in contact with the bond. Bricks which have undergone very intense heating when in use generally show a very high proportion of tridymite, the original quartz and cristobalite having disappeared. Some sections show nothing but aggregates of minute overlapping hexagonal plates of tridymite enclosed in a network of interstitial glassy material, each aggregate representing an original crystal of quartz. When cristobalite occurs in these tridymite-bricks it forms well-developed skeletons in the glassy bond between the original rock-fragments. In other bricks composed largely of tridymite, the latter is of the simple twinned form and fairly large crystals occasionally develop. Pseudo-hexagonal tridymite never occurs in bricks which have proved bad in practice, but the simple twinned form is common in such bricks. Repeated heating at temperatures varying from cones 13 to 16 (1380° to 1460° C.) and prolonged heating at temperatures varying between 1500° and 1600° C. both yield tridymite as the end-product. The author supports Le Chatelier (this J., 1917, 961) and disagrees with Fenner (this J., 1913, 22); he is of the opinion that tridymite is stable at temperatures above 1400° C. When cristobalite occurs in bricks which have been heated for long periods to 1600° C., it always occurs in the matrix or along the margins of tridymite grains and has probably been formed by partial solution of the tridymite in the matrix (which is molten at 1500°—1600° C.) and reprecipitation as the brick cools. Quartz is probably stable up to 870° C., tridymite up to 1570° C. (its melting point), but any dissolved silica which is reprecipitated as cristobalite may invert to either quartz or tridymite according to the temperature. Cristobalite appears to have no stable range below 1300° C. The nature of the bond used in the manufacture of silica bricks may affect the rate of inversion. It is desirable to convert as much of the quartz as possible into tridymite, because this is the most stable form at high temperatures and because the volume-change from α - to β -tridymite is less than that from α - to β -cristobalite. The changes in the volume

of bricks are often much greater than would be expected from a consideration of the changes from one form of silica to another. Thus, instead of the theoretical increase of 13 to 16%, the author has observed an increase of over 30%. The excess is probably due to the newly-formed crystals not being oriented so as to occupy the minimum space. W. D. Ross (Trans. Amer. Ceram. Soc., 1917, 19, 83—93) has found that on heating a silica brick to 1500° C. the average volume expansion was 9.7%, but the reduction in sp.gr. only 2.8%. The pseudohexagonal tridymite was found in bricks with a low expansion in use. The occurrence of this type of volume increase is an additional reason for carrying the conversion as near completion as possible in the manufacture of the bricks.—A. B. S.

Silica bricks; Estimation of proportions of quartz, tridymite, etc., in —. A. Scott. Trans. Ceram. Soc., 1917—1918, 17, 188—191.

Owing to the impurities present, the determination of the sp.gr. of silica bricks only gives a very rough idea of the proportion of the various forms of silica present. The same is true of the separation of the constituents by means of dense liquids. Sorby's method of measuring the area of the various crystals when seen under the microscope is accurate, but tedious. Rosiwal has improved it by measuring the intercepts which the particles of each constituent make with a number of arbitrary lines, but the method is difficult to apply to the determination of more than one constituent of silica bricks owing to the fineness of the grains of cristobalite and tridymite; it, however, gives excellent results in about an hour, in estimating the percentage of unaltered quartz, with an error of less than 1%. Details of the method of measurement are given. It is desirable to measure intercepts totalling about 1500 units.—A. B. S.

Chemical stoneware; Standardisation of —. H. Nielsen and J. R. Garrow. Chem. Trade J., 1918, 62, 157—158, 179—180, 225—227. (See this J., 1918, 57 A.)

STONEWARE pressure vessels (montejus, acid-eggs, and vacuum receivers) should as far as possible be spherical, flattened curves being avoided. A maximum wall-thickness of 2½ ins. is suggested, several small vessels being preferred to one larger one. Such vessels should be sunk in wooden boxes filled with sand. An armour of cast iron, steel, or lead should be avoided, its use giving rise to a false sense of security. For a spherical vessel,

the theoretical wall-thickness required is $W = \frac{dp}{2U}$,

where W = the wall-thickness in ins., d = the internal diameter in ins., p = the pressure in lb. per sq. in., and U = the tensile strength of the material. A margin of safety of 2 is regarded as sufficient, i.e., the actual wall-thickness should be twice the theoretical value. Illustrations showing the relative dimensions of the various parts are given. For large montejus, egg-ended cylinders of the same internal diameter and over-all height as the spherical ones, but with double the capacity, are suggested. The use of thin necks for liquid inlets and outlets on heavy vessels is condemned, a square boss into which is ground a standard pipe with a standard taper being preferable. In the boss are two longitudinal holes; a bolt is passed through each of these holes and these bolts serve to keep in position four eye-bolts passing through the bolt holes in the iron armature of the vessel. Maximum sizes for bosses used for montejus are suggested. Storage and transport jars should not exceed 2 tons capacity. Suggestions are made as to the thickness of the walls and other dimensions. The bottoms of the jars should be slightly arched inwards. Outlets should be the same as for

montejus. To prevent the vessels from sweating, they may be filled with a strong solution of sodium silicate, and after a week or more the solution discharged and the vessel treated with strong acid. The diameter of cylindrical jars should be chosen so that the dies used for making large stoneware pipes or towers may be used. Socketed pipes are suitable for fumes or gases under low pressures, but not for liquids. The pipes used for corrosive fumes should be of the best stoneware, vitrified throughout, with thin walls. The jointing material should be soft and should always remain semi-plastic to facilitate alterations and repairs. The socket should be provided with an asbestos ring slightly less in diameter than the inside diameter of the socket and of slightly larger bore than the pipe; this ring acts as a cushion and forms a good base for the cement. When very hot gases are to be conveyed, care must be taken to prevent the pipes being subjected to sudden changes in temperature. Water-cooling should not be applied to pipes at a temperature above 110° C. Suggested dimensions for standard sizes of pipes and bends are given. Condensing and reaction towers should be of the best material, vitrified as fully as possible and salt-glazed. All fume inlet and outlet sockets should be of ample size and should not impede draught. The bottom of the lowest piece in a tower should be arched inwards. Filling-material should not rest on the arched bottom but should be carried by the sides and by a perforated plate (with square holes) in each section. Each section should be supported by a wooden framework. The liquor outlet should be of the boss type as described for "montejus." For towers of large diameter the perforated plates should be in three parts. The plates should always rest on a thick asbestos cord and not directly of the supporting ledges. The perforations should be so arranged that any cross section along a diameter of the plate will show a sufficient proportion of solid material to provide the requisite strength for carrying the filling material. An average of 50% of perforations in plates up to 3 ft. diameter is suggested, with a smaller percentage for larger sizes. The covers of towers should be domed and should contain the liquor inlet and fume outlet. The expression "stoneware" should be restricted to dense, acid-resisting material used in chemical plant, the term "earthenware" being used for more porous bodies. Stoneware may be regarded as a form of porcelain and should resemble the latter in texture, vitrification, non-porosity, independence of glaze (except for appearance), resistance to chemical corrosion and changes of temperature. No single natural clay will produce an ideal chemical stoneware, but many British clays can be satisfactorily blended with other materials. Glazed fireclay should not be used for chemical stoneware except under scientific control, as its body is essentially porous and hence too much reliance must be placed on the glaze. Economy in manufacture should be sought in a proper arrangement of the kilns and in protecting them from the weather.—A. B. S.

Weathering-products of bricks. S. Nagaya. Kōgyō-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1917, 20, 1183—1204.

THE needle-like crystals which form an efflorescence on bricks are due to sodium sulphate, sodium carbonate, and calcium sulphate. The alkali is derived from the clay of which the bricks are made, the sulphur trioxide is chiefly absorbed from the gases used to heat and afterwards to cool the bricks during the process of burning, and the carbon dioxide is absorbed from the atmosphere. As the growth of the crystals accelerates the composition of the bricks, they should be washed off with water or dilute hydr. chloric acid.

THE needle-like crystals which form an efflorescence on bricks are due to sodium sulphate, sodium carbonate, and calcium sulphate. The alkali is derived from the clay of which the bricks are made, the sulphur trioxide is chiefly absorbed from the gases used to heat and afterwards to cool the bricks during the process of burning, and the carbon dioxide is absorbed from the atmosphere. As the growth of the crystals accelerates the composition of the bricks, they should be washed off with water or dilute hydr. chloric acid.

The author advises an examination of the clay with regard to its fineness and its content of soluble salts, sulphur trioxide, and sulphur; observation of the growth of the weathering products during the drying of moulded brick; determination of the porosity of the bricks; determination of the sulphur-content of the fuel; the use of a reducing as well as an oxidising atmosphere in burning the bricks; and the avoidance of sulphur dioxide in gases in contact with cooling bricks.—A. B. S.

Bone china body: Study of —. Part I. Colour. W. H. Yates and H. Ellam. Trans. Ceram. Soc., 1917—1918, 17, 120—122.

BODIES composed of china clay, bone ash, and Cornish stone in various proportions were cast into cups or pressed into slabs, and fired at Seger cone 9 in a china biscuit oven. The colours of the products varied from very pale cream to yellow and reddish-brown and a deep greenish-blue. Mixtures of china clay and bone ash (without stone) yielded brown colours, but a mixture containing 40% of clay and 60% of bone gave a bluish-green colour. Mixtures of china clay and Cornish stone gave yellowish-brown colours. Mixtures of bone ash and Cornish stone were pale in colour, one containing 40% of the former and 60% of the latter giving the darkest tint. In mixtures with 60% china clay, the brown colour diminished as the proportion of stone increased. In mixtures with 40% china clay, the colour changed from green to blue-green, yellow, and brown as the proportion of bone ash diminished. The greenish-blue became reddish-brown on keeping and other mixtures low in stone also tended to turn brown in time, apparently because of oxidation. A subsequent glost fire tended to clear the colours, but firing in an enamel kiln intensified them. Glazes on bodies deficient in stone and giving greenish-blue and reddish-brown colours tended to craze. The contraction of bodies with excess of stone was high and they tended to blister.—A. B. S.

Bone-china body: Microscopical study of —. H. B. Cronshaw. Trans. Ceram. Soc., 1917—1918, 17, 153—158.

THE series of samples prepared by Yates and Ellam (see preceding abstract) showed, under the microscope, a preponderance of an isotropic and glassy base containing swarms of crystallites, small angular fragments of quartz, relatively large pores, but no minerals having fully developed crystalline forms. The brown colour of some of the pieces appears to be due to a clear brownish glass scattered irregularly through the mass.—A. B. S.

Tiles; Effect of pressure on the subsequent contraction, tensile strength, and crazing of —. E. W. Wain. Trans. Ceram. Soc., 1917—1918, 17, 111—115.

TEST-PIECES made of an ivory body composed of ball clay, china clay, flint, and Cornish stone were subjected to various pressures up to 1220 lb. per sq. in. and were then fired in a biscuit oven at Seger cone 5a. The results obtained show that the greater the pressure, the less the contraction. The tensile strength increases with increasing pressure. Using a glaze with a strong tendency to craze, it was found that the tendency to crazing is lessened when the articles are made under great pressure.—A. B. S.

Chrome-tin pink. E. W. T. Mayer. Trans. Ceram. Soc., 1917—1918, 17, 101—105.

To mixtures of tin oxide, lime, and silica in various proportions was added a constant proportion (3%) of potassium bichromate. The mixtures were heated in unfired cups in a china biscuit oven, crushed, re-heated, wet-ground,

washed, and dried. The products were banded and dipped in lead and leadless glaze respectively. The colours produced were as follows: Mixtures free from lime were lilac, the tint diminishing as the proportion of tin oxide decreased. Mixtures containing no tin oxide were light green. The remaining mixtures were chrome-tin pink, those corresponding to the innermost positions in a triangular diagram of which the corners represented SnO_2 , CaO , and SiO_2 respectively being the most promising. This confirms Seger's previous observations. Good pinks were produced by a mixture containing 20 lime, 50 tin oxide, and 30 silica, with 3% potassium bichromate, to which were added various proportions of calcium fluoride, borax, boric acid, Cornish stone, felspar, and alumina respectively. Calcium fluoride darkens the tint; borax and boric acid respectively increase the richness of the tints. Felspar gives lighter tints than Cornish stone. Alumina inclines the colour to rose pink.—A. B. S.

Magnesian glazes; Effect of — on underglaze colours. C. P. Shah. Trans. Ceram. Soc., 1917—1918, 17, 106—110.

THE effect of a magnesian glaze containing 0.1 equiv. MgO in its formula on various underglaze colours was studied and it was found that the colour of light browns due to iron oxide and potassium bichromate is destroyed. Victoria greens are completely altered in tone and other greens are modified. Crimson colours are entirely destroyed and most of the colour in pinks is destroyed. Cobalt blues are not affected. Bluish-greens containing cobalt and chromic oxides are slightly changed. A black composed of cobalt, nickel, iron, manganese, and chromic oxides is greatly improved. Yellow and orange are not affected; fawn is altered when printed, but not when aerographed.—A. B. S.

PATENTS.

Glass and glass tubing; Apparatus for drawing cane —. J. Gray, London. From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 113,892, June 12, 1917. (Appl. No. 8400 of 1917.)

THE patent relates to improved mechanism for operating the gripping, cooling, chilling, and cutting devices of the apparatus described in Eng. Pat. 105,285 (this J., 1917, 551), whereby the speed of drawing and the output of the machine are considerably increased without materially increasing the percentage of breakage.

[Sheet] glass manufacture. T. J. McCoy, Kane, Pa. U.S. Pat. 1,255,450, Feb. 5, 1918. Date of appl., Apr. 4, 1912.

AN apparatus for making sheet glass comprises a tank to contain the molten glass, this tank having an extended end portion with its bottom inclined upwards to form an outer wall and adapted to form the glass flowing over it into a sheet of progressively reduced thickness. A movable carrier diverts the glass from a vertical to a horizontal plane and conveys it away. The thickness of the sheet may be regulated by means of a refractory body placed above the extended portion of the tank and movable vertically. The extended portion is suitably heated.—A. B. S.

Grindstones [Composition for —]. C. Assirate, London. Eng. Pat. 113,557, June 11, 1917. (Appl. No. 8317 of 1917.)

GRINDSTONES are made of a mixture of 1 lb. of emery powder of any grade, 4 oz. of water-glass, and $\frac{1}{2}$ oz. of cobalt oxide powder, baked at a temperature of 450°—600° F. (about 230°—320° C.) for from 3 to 6 hrs. The cobalt oxide is added for hardening purposes.—A. B. S.

Dryer [for bricks]. E. B. Ayres, Assignor to The Philadelphia Textile Machinery Co., Philadelphia, Pa. U.S. Pats. (A) 1,255,685 and (B) 1,255,686, Feb. 5, 1918. Dates of appl., May 3, 1916, and Mar. 16, 1917.

(A) THE dryer is divided into sections in each of which air is circulated independently by a fan. The final section has a separate supply of heated air which is directly discharged from this section in order that the bricks may be thoroughly dried. (B) The chambers of the dryer are separated by movable curtains, so that the bricks can be transferred from one chamber to another. Hot air is supplied to the last chamber and passes from chamber to chamber through connecting flues, the moist air being discharged from the first chamber to an exhaust flue. The bricks are supplied to the first chamber and moved forwards in the opposite direction to the air.—W. H. C.

Enamel; Composition and process for making —. P. Eyer, Halberstadt, Assignor to R. Koepf und Co., Oestrich, Germany. U.S. Pat. 1,256,455, Feb. 12, 1918. Date of appl., July 21, 1915.

SEE Eng. Pat. 100,777 of 1916: this J., 1918, 124A.

Enamel composition and process of manufacturing it. P. Eyer, Halberstadt, Assignor to R. Koepf und Co., Oestrich, Germany. U.S. Pat. 1,256,456, Feb. 12, 1918. Date of appl., Feb. 14, 1917.

SEE Eng. Pat. 101,802 of 1916: this J., 1917, 388.

IX.—BUILDING MATERIALS.

Portland cement; Le Chatelier's boiling test for —. T. Hattori and K. Fujisawa. Kōgyō-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1917, 20, 1205—1212.

IT is difficult to obtain concordant results in Le Chatelier's boiling test for cement on account of the error due to the moulds. The expansion due to dipping in water immediately after moulding should be noted, as it may exceed the expansion due to boiling. The former may be reduced by aeration; the latter increases with the time of boiling up to a certain limit. The authors consider that it is not necessary to boil for 6 hrs., the time usually specified; in one case the same expansion was observed after boiling for 3 hours as after 10 hours.—A. B. S.

Portland cement; Grit in —. T. Hattori. Kōgyō-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1917, 20, 1212—1221.

THE grit which passes through a sieve with 900 meshes per sq. cm., but is retained on a 2500-mesh, consists chiefly of irregular particles which may cause the cement to expand in the boiling test. On replacing the grit by sand particles of the same size, no expansion occurs. The flour-cement is richer in sulphur trioxide than the grit, owing to the extreme minuteness of the calcium sulphate present. By removing the grit the soundness of the cement is improved. Insoluble residues of sand and raw clay and free lime would be removed simultaneously.—A. B. S.

Brick and mortar in the Great Wall of China; Composition of —. J. C. Witt. Philippine J. Sci., 1918, 12 A, 257.

SAMPLES of brick and mortar, apparently part of the original structure of the Great Wall of China (3rd century B.C.), had the following composition:—

	Loss on ignition.	SiO ₂ .	Al ₂ O ₃ + Fe ₂ O ₃ .	CaO.	MgO.	Na ₂ O + K ₂ O.
Brick	0.10	73.02	18.06	1.23	1.05	5.73
Mortar	43.88	2.12	0.44	48.83	4.03	0.85

The bricks had apparently been sun-dried only, since the material turned red on ignition. The results indicated that no sand had been mixed with the mortar.—C. A. M.

Dolomite; Rate of hydration of calcined —. C. Edwards and A. Rigby. Trans. Ceram. Soc., 1917—1918, 17, 116—119.

SAMPLES of dolomite were calcined at various temperatures between 850° and 1750° C. and then kept in desiccators over water, over 20% sulphuric acid, and over 50% sulphuric acid respectively and weighed every day for ten days. The samples calcined at 1150° C. and above hydrated rapidly until about 20% of water had been absorbed, but afterwards more slowly. The authors suggest that this is due to the lime hydrating rapidly and the magnesia more slowly.—A. B. S.

Inversions in silica bricks. Scott. See VIII.

Estimation of proportions of quartz, tridymite, etc., in silica bricks. Scott. See VIII.

Weathering-products of bricks. Nagaya. See VIII.

PATENTS.

Heat insulation and other purposes; Porous composition of matter for —. H. S. Ashenhurst, Chicago, U.S.A. Eng. Pat. 113,810, Mar. 2, 1917. (Appl. No. 3080 of 1917.)

SEE U.S. Pat. 1,230,085 of 1917: this J., 1917, 880.

Method of slaking lime. Apparatus for hydrating lime. U.S. Pats. 1,255,268 and 1,255,682. See VII.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Steel; Hardening and tempering of —. C. A. Edwards. Manchester Assoc. of Engineers, Feb. 9, 1918. Engineering, 1918, 105, 267—270.

THE principles of hardening and tempering are briefly outlined, and special reference is made to nickel, chromium, tungsten, and chromium-tungsten steels. Stress is laid on the importance of the initial temperature and rate of cooling in dealing with nickel and other alloy steels; and it is pointed out that by carburising the surface of a nickel steel containing Ni 7 and C 0.1%, and allowing it to cool slowly, the same effect is produced as by carburising and quenching an ordinary mild carbon steel. The influence of the time factor is particularly important in the case of chromium steels; the great diversity of opinion as to the function of chromium in steel, which existed until recently, was due to the non-appreciation of this fact. Investigation with a steel containing Cr 6 and C 0.63% showed that, by increasing the initial temperature, the rate of cooling could be decreased considerably without detriment to the hardening of the metal; this suggested the possibility, subsequently realised, of producing case-hardening effects in steel containing Cr 6 and C 1% by decarburising the surface to below 0.6% C and carefully adjusting the rate of cooling. The influence of chromium and tungsten, separately and together, on the tempering properties of steel are also discussed in connection with the manufacture and treatment of high-speed cutting tools.

W. E. F. P.

[Silver ore] milling practice at the Buffalo Mines, Cobalt, Ont. R. E. Dye. Trans. Canadian Min. Inst., 1917, 20, 11—27.

MILLING practice in the Cobalt district varies: at some mills gravity concentration is still used, the slime tailing being discarded and the sand tailing stacked for future treatment; at others the whole of the ore is converted into slime, which is cyanided. At the Buffalo Mine, up to the time of introduction of flotation, the ore was treated on jigs and tables and the slime cyanided, the sand tailing (with 5—6 oz. Ag) being reserved. An experimental 50-ton Callow unit for the treatment of the accumulated tailings was installed in 1915; this was followed by a 600-ton plant, which is now successfully treating the old tailings as well as those produced at present: no final tailing is discharged except from the flotation plant. The jig and table concentrates are sold to smelters, the tailings being re-ground and subjected to flotation. The cyanide plant treats all the mine and mill slimes and the high-grade plant and flotation cleaner tailings. In the high-grade plant the flotation concentrate and the cyanide precipitate are treated by chloridising roasting; the roasted product is leached with acid which removes copper, and the residue is treated with cyanide. The silver solution is precipitated with sodium sulphide, and the silver sulphide melted down in an oil-fired reverberatory furnace.—W. R. S.

[Silver] ores; Present flotation practice on Cobalt —, J. M. Callow and E. B. Thornhill. Trans. Canadian Min. Inst., 1917, 20, 28—37.

THE first flotation plant at Cobalt was put in operation at the Buffalo Mine in September, 1916, (see preceding abstract). At the present time, seven plants have adopted flotation and use machines of the Callow type. The process as applied to Cobalt ores has not replaced gravity concentration, but is a useful adjunct for saving the friable silver minerals and fine leaf silver. Fine grinding (to -100 mesh) is required to separate the values from the gangue. The oil mixture used contains pine oil, coal tar creosote, and coal tar (this J., 1918, 93 A). The recovery varies with the plants; at the McKinley-Darragh-Savage Mines, Ltd., the average for two months was 82.13%. With the exception of the Buffalo Mine, the flotation concentrates produced are shipped to U.S. smelters at a heavy marketing charge, but efforts are now being made towards local treatment.—W. R. S.

Cyaniding flotation concentrate. J. G. Parmelee. Min. and Sci. Press, Sept. 15, 1917, 387. J. Chem., Met., Min. Soc. S. Africa, 1918, 18, 165—167.

CONFLICTING opinions have been expressed on the effect of oil in cyaniding. Laboratory tests proved that it had no effect on the cyanide solution or on the cyaniding of ores in which the metals are not present as sulphides. Sulphides, however, become coated and are thus protected from the action of the cyanide. The oil can be removed by treating the concentrate with alcohol or gasoline, or by roasting at a low temperature. With gold ores, simple roasting is effective, but silver ores require a chloridising roast.—W. R. S.

Copper castings for electrical purposes. G. F. Comstock. Amer. Electrochem. Soc., Oct., 1917. [Advance proof.] 6 pages.

CASTINGS of pure copper of high electrical conductivity are very difficult to obtain as the metal absorbs oxygen with formation of blow-holes and films of copper-cuprous oxide eutectic between the metal grains. Zinc is most usually employed as a deoxidiser; it produces sound castings, but the conductivity is often reduced to 40—50%. The

Titanium Alloy Manufacturing Co. (Niagara Falls) have succeeded in applying silicon as a deoxidiser; large and complicated sand castings have thus been made, the conductivity of which is 75—85% that of pure copper.—W. R. S.

Copper; Analysis of —. W. H. Woodcock. Analyst, 1918, 43, 88.

A METHOD for the analysis of commercial copper containing 99% or more Cu consists in removing about 99% of the copper by electrolysis a solution of 10 grms. of the metal, and then determining the residual copper and impurities in the electrolyte. Nickel is determined in the filtrate from the hydrogen sulphide precipitate, after removal of the arsenic by boiling the solution, by treating the filtrate with bromine, nearly neutralising the solution with ammonia, boiling it for a few minutes, then cooling to 50° C., and adding sodium acetate and dimethylglyoxime dissolved in alcohol. The nickel precipitate is collected after standing for 30 minutes at 50° C., and the iron is determined in the filtrate after the excess of dimethylglyoxime has been decomposed by boiling with an excess of hydrochloric acid and then oxidising with bromine.—W. P. S.

Zinc ferrite; Formation of — [in roasting zinc ores]. E. H. Hamilton, G. Murray, and D. McIntosh. Trans. Canadian Min. Inst., 1917, 20, 168—179.

MOLECULAR proportions of pure zinc oxide and ferric oxide were ground to pass a 120-mesh sieve, intimately mixed, and heated to temperatures ranging between 590° and 870° C. The ground products were leached with hot ammonia and ammonium chloride solution. It was thus found that no combination took place within 8 hours at 590° C., while at 870° C. the combination was complete in one hour. At intermediate temperatures the time factor had a distinct effect on the speed of the reaction. Zinc ferrite ($\text{Fe}_2\text{O}_3 \cdot \text{ZnO}$) is yellowish-brown, magnetic, soluble in hydrochloric acid, insoluble in dilute sulphuric acid. The action of alumina on zinc oxide was similar, but aluminium silicate (e.g., fireclay) was found not to react. Tests in which zinc blendes were roasted at measured temperatures showed that for ores poor in iron, the amount of ferrite formed can be calculated with a fair degree of accuracy, since each unit of iron combines with 0.58 unit of zinc, and the reaction is 90% complete after 4 hours at 760° C. With ores showing a zinc-iron ratio of about 1:1, the amount of ferrite formed was much smaller than that calculated.—W. R. S.

Zinc; The hydrometallurgy and electrolytic precipitation of —. F. D. James. Univ. of Missouri Bull., Aug., 1917. 28 pages.

DATA on roasting and sulphuric acid leaching of blende and electrolysis of the zinc sulphate solution on a laboratory scale are given. The zinc sulphate liquor must undergo careful purification prior to electrolysis. The iron, present mostly in the ferrous state, is removed by adding manganese peroxide followed by lime and roasted ore. The ferric hydroxide carries down arsenic and antimony. The other impurities (copper, cadmium, etc.) are then precipitated by metallic zinc, generally in the form of zinc dust. The purified solution is electrolysed with lead anodes and aluminium cathodes. The zinc deposit is stripped from the latter with a cold chisel, and the clean smooth cathode can be used repeatedly. The effect of impurities is as follows: Very small quantities of arsenic and antimony suffice to prevent the formation of a coherent deposit. Iron contaminates the deposit. Copper deposits on the cathode, then drops off in spongy form; if its quantity is small, it causes black spots and

prevents deposition. Cadmium deposits along with the zinc. Only manganese is beneficial, and if not present it must be added to eliminate iron; it is re-oxidised during electrolysis.—W. R. S.

Zinc extraction; Electrolytic — at Trail, B.C. E. H. Hamilton. American Electrochem. Soc., Oct., 1917. (Advance proof.) 3 pages.

THE electrolytic plant of the Canadian Mining and Smelting Co. was started in April, 1916; it treats ore containing Zn 19–21, Pb 14, Fe 23–31, and S 21–29%. The ore is finely crushed (72% to –200 mesh), roasted in Wedge furnaces until the sulphur is reduced to 5%, and then treated first with partly neutralised spent electrolyte until the latter is neutral. The sulphuric acid used is derived from the gases produced on roasting the ore. Leaching is conducted in a series of Dorr classifiers and thickeners; copper and cadmium are precipitated from the solution by "atomised" zinc, with subsequent filtration. Each electrolytic tank (82 in. long, 27 in. wide, 42 in. deep) has 17 lead anodes, and 16 aluminium cathodes with a total area of 10 sq. ft. The current density is 24 amp. per sq. ft., with a potential difference of $3\frac{1}{4}$ volts across the tanks. The electrolyte contains Zn 7.5, Fe 0.014, Cd 0.003–0.008, Cu 0.0003%, and sometimes Mn, Ca, and Mg; when spent, it assays Zn 3–5, Fe 0.013, and H_2SO_4 5–7%. The cathode zinc is stripped off the aluminium and melted in a reverberatory, giving spelter 99.92% pure. The daily production is about 50 tons.—W. R. S.

Aluminium; Metallography of —. *Preparation and etching of microsections.* R. J. Anderson. Met. and Chem. Eng., 1918, 18, 172–178.

For preparing aluminium and light aluminium alloys for etching, the metal surface is treated with dry, coarse emery paper and then with dry No. 0 French Hubert paper. This is followed by successive treatments with Nos. 00, 000, and 0000 French Hubert papers—all thinly coated with paraffin wax (to prevent the entrance of fine particles of emery into the metal)—and the surface is then polished, first with tripoli on a duck-covered board, and finally with a good, non-alkaline metal polish, or with No. 3 levigated alumina, on fine broadcloth or old, well-washed calico. Only light rubbing or pressure is required, owing to the softness of the metal. For etching, satisfactory results may be obtained by the use of sodium or potassium hydroxide, provided the black deposit produced is removed by means of chromic acid; but, in the author's opinion, hydrofluoric acid is the best reagent. With a 15% aqueous solution of the latter, the structure of cast aluminium is developed in about one minute; the metal surface becomes darkened as the etching proceeds, but the darkening is readily removed by immersion in strong nitric acid for a few seconds. Typical microstructures of aluminium as cast, rolled, annealed, etc., and of cast aluminium-copper and manganese-aluminium alloys are shown in a series of twenty photomicrographs.

W. E. F. P.

Lead; Determination of — as phosphate, and its separation from antimony. G. Vortmann and A. Bader. Z. anal. Chem., 1917, 56, 577–580.

A METHOD, which is useful for the analysis of hardened lead, depends on the quantitative precipitation of lead as phosphate from an ammoniacal solution containing a tartrate. The solution, containing about 0.5 gm. of lead nitrate, is treated with 5 grms. of tartaric acid, then made slightly ammoniacal, heated to 80° C., and treated with 100 c.c. of 10% ammonium phosphate solution (sodium or potassium phosphate must not be used). The mixture is maintained at

about 75° C. for 16 hours, cooled, the precipitate collected, washed with dilute ammonium nitrate solution, dried, ignited at a low temperature, and weighed. If a sufficient quantity of tartaric acid is present, antimony is not precipitated under these conditions and may be separated as sulphide from the filtrate from the lead phosphate.

—W. P. S.

Metal colouring. III. "Hirogane." S. Miyazawa. Kogyō-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1917, 20, 1102–1114.

"HIROGANE" is the name applied to a blood-red coloured metal prepared either by treatment of copper with an aqueous solution of copper sulphate and verdigris or by heating a copper alloy with a paste containing a salt of copper, borax, and some water. The coloration of various kinds of alloys known as "Shakudo" and "Shibuichi" (this J., 1916, 884) has been shown to be due to the formation of a thin layer of cupric oxide on the surface of the alloy in consequence of a local electric circuit which causes the cupric ion to be produced and the solubility limit of cupric hydroxide to be exceeded. In this case the layer nearest the surface of the alloy may consist mainly of cuprous oxide produced by the reduction of precipitated cupric hydroxide by metallic copper in the boiling solution of the salt. If, instead of an alloy, metallic copper is treated, the local electric circuit will be absent and the formation of the cupric ion very restricted, with the production of an extremely thin layer corresponding to the layer of cuprous oxide nearest the surface of the metallic copper, as in the case of "Shakudo." Any further formation of the layer of cupric oxide takes place with difficulty. Thus the blood-red colour of "Hirogane" may be due to the colour of mixed cuprous and cupric oxides. In the dry method, the salt of copper changes to cupric oxide and this coating of oxide is removed by polishing until the layer of cuprous oxide nearest the metal is reached, giving the metal a dark red colour. The author, without polishing the coating of oxide, obtained a brighter red colour by heating the metal with the paste on its surface and placing it in water or boiling it in the same solution of salt as is used for colouring "Shakudo." This result is possibly due to the partial reduction of cupric to cuprous oxide.—J. F. B.

Manufacture of crude sodium manganate. Wartenweiler. See VII.

PATENTS.

Ingot-iron and steel; Manufacture of —. Deutsch-Luxemburgische Bergwerks- und Hütten-A.-G., Bochum, and A. Klinkenberg, Dortmund, Germany. Eng. Pat. 113,512, Mar. 7, 1917. (Appl. No. 3398 of 1917.) Addition to Eng. Pat. 105,548 (this J., 1917, 1277).

PEAT and brown coal or other combinations of carbon, hydrogen, and oxygen, which on heating generate gas and do not part with more than 50% of their total carbon, are used instead of the carbohydrates prescribed in the chief patent, to deoxidise iron and steel baths rich in oxygen. The materials mentioned may also be used for the treatment of iron and steel baths free from oxygen and of iron alloy baths for the purpose of carbonising them.—T. H. B.

Iron and steel; Process of producing —. S. McDonald, Alhambra, Cal. U.S. Pat. 1,255,191, Feb. 5, 1918. Date of appl., Dec. 6, 1916.

A QUANTITY of iron ore is melted on the top of a molten charge of iron or steel in a crucible, and a combustible gas or a non-oxidising gas mixed with powdered carbonaceous material is blown

downwards against the iron ore. Some of the ore is carried below the surface of the metal and is reduced to iron or steel.—W. F. F.

Wrought-iron; Manufacture of — J. Ashton, Assignor to A. M. Byers Co., Pittsburgh, Pa. U.S. Pat. 1,255,499, Feb. 5, 1918. Date of appl., Aug. 18, 1917.

DISINTEGRATED refined iron is heated to welding heat in a bath of molten slag having a lower melting point than the iron, and the mingled slag and iron then subjected to squeezing and rolling.—W. F. F.

Ores; Method and apparatus for concentrating by flotation — G. Gröndal, Djursholm, Sweden. Eng. Pat. 108,308, July 7, 1917. (Appl. No. 9852 of 1917.) Under Int. Conv., July 26, 1916.

A GASEOUS fluid carrying oil is introduced in the form of a large quantity of very small bubbles at the bottom of a vessel into which the ore pulp is also delivered. The mixture flows through an opening into an adjoining narrow chamber in which the froth forms a high column which overflows into a discharge conduit for concentrate whilst the gangue sinks to an outlet at the bottom. Sets of chambers and receptacles are combined for passage of the liquid and mineral particles through them in succession.—T. H. B.

Ilmenites or titanite iron ores; Process for the treatment of — P. Raffin et Fils, Nice, France. Eng. Pat. 111,668, Nov. 19, 1917. (Appl. No. 17,036 of 1917.) Under Int. Conv., Nov. 21, 1916.

CONCENTRATION to a high content of titanite oxide is effected by adding an agglutinant such as tar or carbonaceous oil to a mixture of ilmenite and pulverised carbon, heating to between 900° and 1100° C., and subjecting the product to the action of dilute sulphuric or hydrochloric acid to dissolve iron. The ilmenite is previously deprived of silica and other impurities by magnetic separation.—T. H. B.

Ores; Electro-chemical process for the treatment of metallic — C. O. Griffith, Wormit, Fife. Eng. Pat. 113,508, Mar. 6, 1917. (Appl. No. 3285 of 1917.)

IN the production of metallic sulphides, e.g., of antimony, along with by-products such as sodium hydroxide or other compounds, an electric current is passed through a cell containing an electrolyte of sodium or other chloride, the anode being formed of a metallic ore or concentrate, whilst the cathode is of any suitable material. The necessary sulphur is supplied by the decomposition of a sulphide ore used as the anode, or by the cathode having a layer, block, or cake of sulphur near or in contact with it, or by adding a thiosulphate or other sulphur compound to the electrolyte, the cathode in the latter case being enclosed in a separate compartment by means of a porous partition.—B. N.

Furnaces; Metal heating, metallurgical and analogous heating — The Richmond Gas Stove and Meter Co., Ltd., Warrington, and J. Thompson, Sheffield. Eng. Pat. 113,591, May 14, 1917. (Appl. No. 276 of 1918.)

A METAL-HEATING furnace has a stationary heat-guard of asbestos held between metal plates, at its front and working face. There is an opening in the guard, closed by a movable transparent screen (e.g., of mica), through which articles or instruments can be passed into the furnace, and the interior of the heating chamber can be seen. By means of a pipe with a row of holes in its upper surface an upward stream of air under pressure is delivered between the furnace front and the guard.—T. H. B.

Zinc; Recovering — from its solutions. F. Laist and J. O. Elton, Assignors to Anaconda Copper Mining Co., Anaconda, Mont. U.S. Pat. 1,255,433, Feb. 5, 1918. Date of appl., June 16, 1916.

ZINC is deposited electrolytically on a cathode of metal, e.g., pure aluminium, which is electropositive to zinc, and is substantially free from impurities which are electronegative to zinc, until a deposit suitable for stripping is formed.—W. F. F.

Zinc-bearing solutions; Method of purifying — F. Laist and J. O. Elton, Assignors to Anaconda Copper Mining Co., Anaconda, Mont. U.S. Pats. (A) 1,255,434 and (B) 1,255,435, Feb. 5, 1918. Date of appl., June 16, 1916.

(A) A SOLUTION containing zinc is agitated with finely divided zinc to precipitate a portion of the copper, and then further purified by contact with moving zinc surfaces in a tube mill. The zinc-bearing material carried forward by the solution is collected and returned to the purifying system at the first stage. (B) An electric current is passed through the solution from an anode surface of electrolytically deposited zinc sponge to produce a deposit of zinc sponge, and the solution is then agitated in contact with finely-divided zinc. Zinc may then be deposited electrolytically from the purified solution.—W. F. F.

Zinc; Process of recovering — from ores. F. Laist and J. O. Elton, Assignors to Anaconda Copper Mining Co., Anaconda, Mont. U.S. Pats. (A) 1,255,436 and (B) 1,255,439, Feb. 5, 1918. Dates of appl., June 16 and July 10, 1916.

(A) IN a cyclical process of recovering zinc from ores also containing arsenic or antimony, the ore is alternately leached with an acid solvent for zinc, and the zinc deposited electrolytically from the resulting solution. An acid solution containing a ferrous salt is oxidised by means of a manganese compound which is more highly oxidised than the corresponding manganous compound. The resulting ferric and manganous solution is added to the leach solution subsequently to the electrolysis, in proportion sufficient to eliminate arsenic and antimony. The ferric compound is then removed by precipitation together with the arsenic and antimony prior to the succeeding electrolysis. (B) Zinc ore is leached with an acid solvent for zinc, iron is precipitated from the solution as a ferric compound, and the solution then treated with finely-divided zinc to precipitate metals electronegative to zinc. Zinc is deposited electrolytically in spongy form from portions of the solution with zinc anodes for use in the earlier stage of the process and further quantities of zinc are deposited as reguline metal with insoluble anodes. The resulting acid solution is used for the preliminary leaching operation.—W. F. F.

Metals [e.g., zinc]; Electrodeposition of — F. Laist and J. O. Elton, Assignors to Anaconda Copper Mining Co., Anaconda, Mont. U.S. Pat. 1,255,437, Feb. 5, 1918. Date of appl., June 16, 1916.

IN the deposition of metals, e.g., zinc, by electrolysis, in which a purifying system, storage system, and main electrolytic system are combined, the solution flows through an "indicator cell" between the purifying and storage systems.—W. F. F.

Zinc ores; Process of treating — Process of treating complex ores or concentrates therefrom. F. Laist, Assignor to Anaconda Copper Mining Co., Anaconda, Mont. U.S. Pats. (A) 1,255,438 and (B) 1,255,440, Feb. 5, 1918. Dates of appl., July 10 and Nov. 3, 1916.

(A) ZINC ore containing iron is calcined and leached with dilute sulphuric acid. The iron is precipitated from the solution by a material con-

taining zinc oxide and the precipitate separated from the solution. The precipitate is calcined at a temperature below that of the first calcination, but at which the ferric compounds are rendered insoluble whilst the zinc sulphate is not decomposed. The latter is then extracted from the mixture. (B) Ores or concentrates containing zinc, lead, copper, and precious metals, are roasted and then leached with dilute sulphuric acid. The solution containing zinc is separated and purified, and the zinc deposited electrolytically. The residue containing the remaining metals and some zinc is smelted so that oxides of lead and zinc are volatilised, and a matte containing copper and precious metals is produced. The volatilised product is treated with dilute sulphuric acid to extract zinc, leaving a residue rich in lead, and the copper and precious metals are recovered from the matte.—W. F. F.

Blast-furnace stoves; Gas burners for—S. Sugimoto, Honkeiko, S. Manchuria. Eng. Pat. 113,740, July 31, 1917. (Appl. No. 11,032 of 1917.)

Plating ferrous metals [with tin]; Method of—W. E. Watkins, New York, Assignor to The Metals Plating Co. U.S. Pat. 1,256,084, Feb. 12, 1918. Date of appl., Nov. 11, 1914.

SEE Eng. Pat. 18,932 of 1914; this J., 1916, 53.

Titanium ores; Concentration of—M. R. Raffin, Assignor to P. Raffin et Fils, Dunkirk, France. U.S. Pat. 1,256,368, Feb. 12, 1918. Date of appl., July 6, 1917.

XI.—ELECTRO-CHEMISTRY.

Sulphur dioxide; Depolarisation by—M. de K. Thompson and A. P. Sullivan. Met. and Chem. Eng., 1918, 18, 178—179.

IN continuation of previous work on the electrolytic oxidation of sulphurous acid (this J., 1917, 81), experiments have been made on the use of sulphur dioxide as a depolarising agent. Constant currents were passed through an electrolytic cell of special design (containing an anode compartment through which sulphur dioxide could be passed when required), and the anode potentials under the various conditions were measured against a standard electrode. In 10% and 16.5% solutions of sulphuric acid and copper sulphate, sulphur dioxide was found not to depolarise a smooth platinum anode at current densities above 10 and 6.2 amp. per sq. dm., respectively. In both solutions, the voltage of the anode was decreased by about 1.5 volts unless certain limits of current density were exceeded; this limit was between 7.5 and 10 amp. per sq. dm. for the sulphuric acid, and less than 7.5 amp. for the copper sulphate solution. These results are not in agreement with those obtained by M. R. Thompson (Met. and Chem. Eng., 1917, 16, 178) who found that with an anode of platinum black in a solution of copper sulphate, sulphuric acid, and sulphurous acid, sulphur dioxide ceased to depolarise at a current density of 3.23 amp. per sq. dm. Further results indicated that the current density at which depolarisation ceases is largely dependent on the metal of the electrode.—W. E. F. P.

Insulation; Electrical—W. T. Cushing, Assignor to The Cutler-Hammer Manufacturing Co., Milwaukee, Wis. U.S. Pat. 1,255,139, Feb. 5, 1918. Date of appl., Sept. 9, 1915.

AN electric insulating composition comprises an asbestos base, and a binder including a varnish of East India gum, China wood oil, and rosin, with a mixture of two parts of stearin pitch and one part of coal tar pitch for retarding oxidation of the varnish.—B. N.

[Electrolytic] cell. J. L. Malm, Assignor to The Midwest Metals Co., Denver, Colo. U.S. Pat. 1,255,197, Feb. 5, 1918. Date of appl., Apr. 26, 1915.

THE cell chamber is provided with a central trough-like well opening out through the cell wall: a metal cathode fills the well, so that the upper surface only of the cathode is in contact with the electrolyte, and the end portion extends through the side wall of the chamber. The anode substantially fills the horizontal section of the chamber and also extends through the wall. To ascertain the height of the electrolyte and the deposit of metal, an opening is provided in the anode, fitted with an insulating sleeve, and an opening is provided in the cover in alignment with the insulating sleeve so that a bar may be inserted to touch the bottom of the cell.—W. F. F.

Battery; Electric—R. C. Benner and H. F. French, Fremont, Ohio, Assignors to National Carbon Co. U.S. Pat. 1,255,283, Feb. 5, 1918. Date of appl., July 13, 1916.

THE negative element of the battery consists of copper oxide containing an oil holding sulphur in solution, within a perforated container, in an alkaline electrolyte. The sulphur is incorporated with the depolarising mass by soaking the latter in a hot saturated solution of sulphur in oil, whereby sulphur crystallises out on cooling.—B. N.

Electrolyte. J. Coulson, Wilksburg, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,255,391, Feb. 5, 1918. Date of appl., Apr. 5, 1917.

AN electrolyte for electrolytic condensers, lightning arresters, rectifiers, and the like, comprises an aqueous solution containing not more than 2% of potassium arsenate.—B. N.

Electric furnace-control apparatus. A. D. Keene, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,255,613, Feb. 5, 1918. Date of appl., Sept. 5, 1917.

THE furnace comprises two movable electrodes and a stationary conductor, with an electrical circuit connected to the electrodes for operating several arcs in series between the movable electrodes and the stationary conductor. Means, operated by a motor, are arranged for adjusting one of the movable electrodes in response to variations of the current in the circuit. A resistance, as a shunt to the arc from the current-controlled electrode, and a motor-operated means are arranged for adjusting the second electrode in response to variations of voltage in the circuit.—B. N.

Uninflammable liquids adapted for use in insulating and other similar purposes. G. Lépine, Neuchâtel, Switzerland, U.S. Pat. 1,255,618, Feb. 5, 1918. Date of appl., June 29, 1917.

A MIXTURE of 80 parts of pentachloroethane, 18 parts of pentachlorobenzene, and 2 parts of hexachlorobenzene, with the addition of 1 part of toluidine.—B. N.

Electric transformers, especially suitable for use in connection with electric furnaces. J. Bibby, London. Eng. Pat. 113,899, June 22, 1917. (Appl. No. 9014 of 1917.)

XII.—FATS; OILS; WAXES.

Valenta tests [of fatty oils]; Modified acetic acid reagent for—. A. E. Parkes. Analyst, 1918, 43, 82—85.

THE inconvenience caused by the crystallisation of acetic acid in cold weather may be overcome, as regards the use of the acid in the Valenta test, by employing a mixture of acetic acid and other lower fatty acids together with a small proportion of water. Such a mixture is conveniently prepared by adding 10% of propionic acid or butyric acid and from 1 to 2% of water to glacial acetic acid. The solidifying point of acetic acid is lowered by the presence of water and certain fatty acids, whilst the turbidity temperature in the Valenta test is raised by water and lowered by fatty acids, and by adding 10% of propionic or butyric acid to 99% acetic acid and then water in small quantities (1—2% is generally necessary) a reagent may be obtained which gives the turbidity temperature required when standardised against pure butter or other fat. This mixture of acids remains liquid when cooled to 0° C.—W. P. S.

Cherry-kernel oil. H. L. Maxwell. Chem. News, 1918, 117, 122—124.

THE kernels from dried cherry stones, *Prunus cerasus*, yielded on extraction with ether 37.6% of an amber-coloured oil with an odour of almonds. It gave a deposit at -5° C., became solid at -20° C., and had sp. gr. 0.922 to 0.925, and saponification equivalent 276.8. Amygdalin was present in the residue, which contained 4.2% of nitrogen.

Comparison of linseed oil and lumbang oils as paint vehicles. Aguilar. See XIII.

PATENTS.

Oil from seeds and like oleaginous materials and substances; Apparatus for the extraction of—. C. Downs and R. A. Bellwood, Kingston-upon-Hull. Eng. Pat. 113,530, Apr. 2, 1917. (Appl. No. 4711 of 1917.)

THE solvent for the extraction of oil from seeds, etc., is passed through a preliminary heater where it is heated by means of vapours coming from the evaporator, and then passes through a second heater in which it is heated by steam to the required temperature before introduction into the extraction vessel. The preliminary heater is preferably arranged between the evaporator and the condenser, and may be provided with means whereby the solvent may be conducted to the evaporator without passing through the second heater. It may also be connected directly with the condenser by means of a pipe provided with a trap.—C. A. M.

Catalyser [for hydrogenation processes] and process of making same. C. Ellis, Montclair, N.J. U.S. Pat. 1,255,590, Feb. 5, 1918. Date of appl., Sep. 21, 1916.

A CATALYST for use in the hydrogenation of organic substances consists of a compound of a metalloid element and a catalytic metal (e.g., nickel boride), which is protected from atmospheric oxidation (e.g., by means of a seal of oily material) prior to the hydrogenation. An active base may be used as the vehicle for the non-oxidised catalytic compound.

—C. A. M.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Acroplane dopes. G. J. Esselen, jun. J. Ind. Eng. Chem., 1918, 10, 135—137.

THE specification of the Bureau of Standards, U.S.A., requires the tensile strength of linen fabrics to be increased by at least 25% and that of cotton fabrics by at least 15% after treatment with a dope. The average weight of a suitable fabric for aeroplane wings is about 3½ to 4 oz. per sq. yd., and the tensile strength about 90 to 100 lb. per inch width. As a rule the dope when dry adds about 2 to 2½ oz. per sq. yd. to the weight, but in certain types of war machines the combined weight of fabric and dope does not exceed 6 oz. The dopes used consist essentially of a solution of cellulose nitrate or of cellulose acetate (about 8 oz. per gall.) in mixtures of amyl acetate and acetone, or (for cellulose acetate) in acetone or mixtures of tetrachloroethane and alcohol. In Europe only acetate dopes are used, but in America pyroxylin dopes are also used, whilst some manufacturers attempt to reduce the inflammability by applying coats of acetate dope above the pyroxylin coats. A dope has better penetration, adheres better, and offers greater resistance to the atmosphere when applied to unsized fabrics than to sized fabrics. Dopes are usually tested by applying them to linen stretched on frames about 12 to 15 in. square, which are then exposed on a roof. This test varies with the season of the year, and although the length of time before the flexibility of the fabric disappears affords a measure of the relative value of different dopes, the conditions are not quite parallel with those which obtain in service since the effect of vibration is wanting. If, however, a dope remains flexible, vibration alone would not cause it to crack. The Bureau of Standards requires a dope to retain its flexibility for at least 60 days when exposed to the weather. The exposed fabric shows a certain amount of weakening, which is more pronounced with nitrate than with acetate dopes, and with cotton than with linen fabrics. In one case a cotton fabric treated with a nitrate dope had its tensile strength reduced to 48.5% of the original after 3 weeks' exposure, whilst linen coated with the same dope showed a reduction to 68% of its original strength. With an acetate dope the corresponding reductions in the strength of cotton and linen were 87.2 and 84.8% respectively of the original values. The presence of tetrachloroethane in a dope gives a resilience to the aeroplane wing which no other constituent does, but owing to the poisonous character of the vapour its use is prohibited in England. It is contended, however, that efficient ventilation would eliminate this danger. Cellulose acetate in sheets 10/1000 in. thick, and weighing about 9 oz. per sq. yd., is strong enough for aeroplane wings, and owing to its transparency is almost invisible at a height. It has the drawback, however, that a tear when once started spreads very rapidly.—C. A. M.

Linseed oil and lumbang oils as paint vehicles: Comparison of —. R. H. Aguilar. Philippine J. Sci., 1917, 12A, 235—243.

FRESHLY expressed samples of lumbang bato (batu) oil from *Aleurites moluccana* (candle-nut oil) and of lumbang banucalag oil from *A. trisperma*, had the following characters:—

Oil.	Sp. gr. at 15° C.	Saponif. value.	Acid value.	Iodine value.
Lumbang bato	0.9252	192.95	1.05	150.36
Lumbang banucalag	0.9368	197.74	8.70	145.25

Fresh lumbang bato oil increased 11.03% in weight in 4 days in a drying test, and formed a film which was dry and firm in 4 to 6 days, whilst fresh banucalag oil increased 8.92% in weight, and formed a film which was dry but slightly opaque in 4 days. Boiled and old oils dried much more rapidly than the fresh samples. Paint films were prepared by Gardner's method of applying the paint to paper sized with glue, and when dry removing the film by immersion in water at 40° C., washing it free from glue, and suspending it on a glass rod to dry. The "paint" consisted of 15% of precipitated silica incorporated with the oil, and the films were made by applying 3 coats of 2.5 grms. each to 400 sq. cm. of sized paper. The strength and elasticity of the films were tested by means of a modification of the machine of Gardner and de Horvath (Gardner, "Paint Technology and Tests," New York, 1911, p. 79), in which a mercury manometer was used for measuring the pressure. The oil-silica films became soft and tacky, and were greatly reduced in strength after 60 days. In the case of films prepared from a mixture of 40 grms. of red lead with 25 grms. of oil, the maximum strength was reached between the third and fourth month, and subsequently there was a gradual decrease in the strength. The mixture of lumbang banucalag oil and red lead became thick and pasty in 15 mins., whereas lumbang bato oil did not behave in this way. Hence, banucalag oil by itself is not a satisfactory paint medium, although when mixed with lumbang bato oil in the proportion of 1:1 to 3 parts, it yields a rapid-drying and satisfactory paint. Mixtures of the two oils containing 50 to 75% of lumbang bato oil do not "set" as in the case of linseed or lumbang bato oil when incorporated with red lead, and do not dry into a paste in the containers. The moisture-excluding capacity of the films was determined by fastening pieces with Canada balsam over the mouths of 200 c.c. bottles containing calcium chloride or strong sulphuric acid, and determining the percentage increase in weight of the drying agent after an exposure of from 5 to 60 days. It was found that the moisture-excluding property of lumbang bato oil-red lead paint films was not as high as that of the corresponding linseed oil-red lead films. For example, in the case of sulphuric acid the increases in weight with the linseed oil and lumbang bato oil films after 5 days were 0.24 and 0.42%, and after 40 days 1.67 and 3.03%, respectively. Mixtures of lumbang bato and lumbang banucalag oils in the proportions of 75 and 50% of the former yielded red-lead paint films which excluded moisture almost as well as linseed oil films, and such mixtures therefore appear to be suitable paint media.—C. A. M.

7-Alkali resin soaps; Colloidal nature of the —. L. Paul. Kolloid Zeits., 1917, 21, 176—191.

SOLUTIONS of the alkali resin soaps behave like highly disperse colloidal systems. The colloidal

soaps combine with basic dyes to form coloured resin lakes and are also characterised by the readiness with which they combine with petroleum hydrocarbons. (See also J. Chem. Soc., Apr., 1918.) —H. M. D.

Brewers' pitch. Eckhardt. See XVIII.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber: Testing of—. A. van Rossem. Communications of the Netherlands Govt. Inst. for Advising the Rubber Trade and the Rubber Industry. Int. Assoc. for Rubber Cultivation in the Netherland Indies, 1917, Part V., 125—175.

It has been found that different plantation rubbers, mixed with sulphur in the proportion 92½:7½, show with a certain vulcanisation coefficient approximately the same stress-strain curve. Raw rubber should therefore be judged by its rate of vulcanisation and by its mechanical properties in comparison with the average values corresponding with the vulcanisation coefficient obtained under the standard method of vulcanisation. Rubber goods on the other hand should be tested as far as possible from the point of view of their intended application. For example, to test vulcanised rubber cylinders as to their behaviour under compression, a sample cylinder is enclosed in a steel cylinder of slightly greater diameter and then compressed by a steel piston, the pressure and corresponding compression being recorded in the form of a hysteresis loop on a chart. An examination has been made of the relative quality of Tjipetir gutta-percha collected from twigs and leaves respectively, the composition, specific insulating resistance, and puncture voltage of each quality being tested as well as the viscosity in benzene and carbon tetrachloride; both qualities were found to contain a high percentage of pure gutta-percha and to compare very favourably with the wild product, the leaf variety being slightly the better of the two. In testing the insulating material of so-called "normal-rubber-insulated wire," rigid adherence to the specified composition, viz., a minimum of 33.3% rubber and maxima of 6% resins, 66.7% filler (including sulphur), and 1% alcoholic potash extract is considered essential, and the further reduction of the maxima for resins and alcoholic potash extract to 5% and 0.5% respectively is suggested, together with additional mechanical tests as to the tensile qualities in order to check the use of reclaimed rubber.

Details are given of the standard vulcanisation method employed for testing raw rubbers, the rubber-sulphur mixture being finally heated by steam for 1½ hours at 52 lb. pressure or 148.25° C. It has been found more convenient, however, to dispense with steam as a source of heat. Vulcanised specimens free from porosity can easily be obtained by other methods if the surrounding pressure during vulcanisation is maintained above the vapour tension of water at the temperature of the rubber; an apparatus is described in which discs of the rubber-sulphur mixing 7.5 cm. in diameter and 5 mm. thick, enclosed with a little water in small moulds, are vulcanised by being suspended in a bath of liquid paraffin at 147° C. for 1½ hours, this temperature giving the same chemical and physical results as the steam treatment at 148.25° C. The new method also has the advantage that further samples may be introduced at any time without appreciably affecting

the temperature of the bath, and that the transference of heat occurs more rapidly than in the older method. For the determination of the coefficient of vulcanisation, the combined sulphur in an acetone-extracted sample is estimated by Rothe's method with magnesium nitrate; the free sulphur in the acetone extract is estimated by Frank and Marckwald's method, but if the amount exceeds 1%, its calculation from the difference between the combined sulphur and total sulphur is preferred. As the amount of resinous matter that can be extracted by acetone is practically unaffected on vulcanisation, it is often convenient to determine the free sulphur merely by making comparative acetone extracts on the raw rubber and on the vulcanised mixing and then, knowing the percentage of sulphur added to the rubber, to obtain the figure for combined sulphur by difference. Numerous experiments made by the Institute lead to the important conclusion that for rubber-sulphur mixtures there is a close connection between the vulcanisation coefficient, the breaking load, the stress necessary to produce an elongation of 850%, and the percentage permanent deformation. As the result of an examination of various tensile methods for determining the mechanical properties of rubber, the conclusion is drawn that the Schopper-Dalen machine possesses marked advantages over the Schwartz machine and still more over the Breuil apparatus. Using the Schopper machine with a standard mixing of 92.5% rubber and 7.5% sulphur, the stress-strain curves only very rarely intersect, and although the breaking strength of various rings of a normally vulcanised rubber may differ considerably the curves are usually coincident; it is therefore possible and advantageous to determine the position of the stress-strain curve by the position of one definite point and this is arbitrarily fixed at the stress in kilos. per sq. cm. necessary to produce an elongation of 850%; the figures for this stress are decidedly more constant than the final tensile strength of different rings made from the same mixing and there is generally a close relationship between them and the coefficient of vulcanisation of the rubber. One ring is usually sufficient for this method of testing. Rubbers which exhibit deviations from the probable curve expected from their coefficient of vulcanisation are classed as abnormal. The method of judging the mechanical properties of a rubber by the product of the breaking load and the elongation at break (Eaton and Grantham, this J., 1915, 989) is regarded as of no advantage whatever, because the position of the maximum value in this case coincides with that of the maximum tensile strength. A comparison of first latex Hevea rubber with Brazilian rubber supports the common view that the latter is more uniform in its rate of vulcanisation, and with the same coefficient of vulcanisation the latter is found to offer a greater resistance than the average plantation rubber to stretching. Permanent set is measured by the Institute by placing Schopper rings over a glass plate with rounded edges for 24 hours, the dimensions being such that the ring is stretched to 400% of its original length; the permanent set generally decreases with an increasing coefficient of vulcanisation. For testing the resiliency of rubber an apparatus is used in which a pendulum with a fall of 205 mm. strikes at its lowest position against a rubber sample placed vertically, the rebound being recorded on a vertical piece of paper which rotates about a vertical axis; the resiliency decreases with an increased vulcanisation coefficient, the decrease becoming much more rapid when the coefficient exceeds 4.5. Such "elastometer" tests are probably of considerable value for examining the effect of "fillers" on the resiliency of rubber but are not considered essential in connection with raw rubber.—D. F. T.

PATENTS.

Rubber ; New agents for accelerating the vulcanisation of — and method of producing the same. S. J. Peachey, Stockport. Eng. Pat. 113,570, Aug. 23, 1917. (Appl. No. 12,085 of 1917.)

PRODUCTS of the interaction of *p*-nitrosodimethylaniline (or its homologues) and sulphur are used to accelerate the vulcanisation of rubber. By heating the substances to about 130° to 135° C. a red vapour is evolved, which condenses, on cooling, to a yellowish-red product, whilst a dark reddish-brown mass is left, which when extracted with acetone or chloroform yields, on evaporating the extract, a dark brown viscous resin. Both the condensed yellowish-red product and the resinous mass may be used as accelerators in the vulcanising process. (See also Eng. Pat. 4263 of 1914; this J., 1915, 368.)—C. A. M.

Impregnating fabrics with rubber ; Machine for —. I. S. McGiehan, New York. U.S. Pat. 1,255,192, Feb. 5, 1918. Date of appl., May 20, 1916.

THE impregnating vat containing rubber solution is provided with drums or rollers for alternately and transversely bending the fabric while it is passing through the solution. The impregnated fabric passes through a compressing machine having spring-pressed rollers with rubber surfaces, geared so as to avoid slipping, which press the rubber into the fabric without distortion of the threads. The static parts of the machine are arranged so that the fabric does not come into contact with them. The fabric finally passes through a drying or semi-vulcanising device.—W. F. F.

Scrap rubber or other like material ; Machines for the treatment of —, known as scrap washers. F. Niblock, Singapore. Eng. Pat. 113,876, May 10, 1917. (Appl. No. 6636 of 1917.)

Vulcanisation of india-rubber and other similar substances. H. Olivier, Paris. U.S. Pat. 1,256,496, Feb. 12, 1918. Date of appl., May 21, 1915.

XV.—LEATHER ; BONE ; HORN ; GLUE.

Gelatin ; Effects of electrolytes on — and their biological significance. I. Effects of acids and salts on the precipitation of gelatin by alcohol. W. O. Fenn. J. Biol. Chem., 1918, 33, 279—294.

THE volume of alcohol required to precipitate gelatin increases with increasing concentration of salts in the solution. In the case of acids and alkalis, the presence of very small quantities entirely prevents the precipitation of the gelatin, whilst with larger quantities the amount of alcohol required slowly diminishes as the concentration of electrolyte increases. The effects of the ions on the precipitation of gelatin by alcohol bear a general resemblance to the effects produced on the viscosity, imbibition, and other properties of gelatin. (See also J. Chem. Soc., Apr., 1918.)—H. W. B.

PATENTS.

Tanning processes. O. Röhm, Darmstadt, Germany. Eng. Pat. 104,338, Feb. 14, 1917. (Appl. No. 2197 of 1917.) Under Int. Conv., Feb. 21, 1916. Addition to Eng. Pat. 103,827.

MODIFICATIONS of the processes of the principal patent (this J., 1918, 14 A) are described. Iron-aldehyde tannage may be advantageously combined with treatment of the unhaired hides with neutralising materials or precipitants of iron, such as alkalis, phenols, vegetable tanning materials, soap, or sulphides. The advantage of a combined

iron-aldehyde tannage may also be obtained by carrying out the aldehyde tannage simultaneously with or after the neutralisation of the leather which follows the metal tannage. This also applies to chrome tanning. The use of mixtures of salts, e.g., a mixture of iron and chromium chlorides, for tanning is also advantageous.—F. C. T.

Tanning or tawing by means of aluminium salts.

O. Röhm, Darmstadt, Germany. Eng. Pat. 110,750, Oct. 13, 1917. (Appl. No. 14,862 of 1917.) Under Int. Conv., Oct. 27, 1916.

THE partial removal of tanning substance with the excess of alum from the hide may be obviated by using an aluminium salt of a lower fatty acid, such as formic or acetic acid, or a mixture of one of these acids with an inorganic aluminium salt, in place of alum as the tanning agent; or the moist leather coming from a tanning liquor containing an aluminium salt may be treated with a solution of a salt of a lower fatty acid, such as formic or acetic acid; or a salt of this kind may be added to the water used for washing leather which has been tanned with an aluminium salt and then dried.

—C. A. M.

Tanning of hides; Apparatus for the —.

G. D'Angelo, Turin, Italy. Eng. Pat. 113,108, Sept. 11, 1917. (Appl. No. 13,036 of 1917.)

A MASONRY vat is provided with heated pipe coils in compartments formed by partitions which act as baffle-plates. The liquor is circulated over the coils, and also through the main part of the tank, by means of a paddle-wheel.—F. C. T.

Hides; Apparatus for treating —. J. E. Vorel, Milwaukee, Wis. U.S. Pat. 1,251,179, Jan. 22, 1918. Date of appl., Mar. 6, 1917.

A TANK for treating hides with liquids is provided with devices for keeping the liquid in motion.—F. C. T.

Production of a nitrogenous fertiliser from leather waste. U.S. Pat. 1,255,643. See XVI.

XVI.—SOILS; FERTILISERS.

Determination of phosphoric acid. Modification of the citrate method. Grossfeld. See XXIII.

PATENTS.

Fertilisers [: Manufacture of —]. G. A. R. Borghesani and G. Stampa, Rome. Eng. Pat. 113,493, Feb. 27, 1917. (Appl. No. 2924 of 1917.)

CRUSHED leucite and phosphorite are mixed with small quantities of nitre-cake and pyrites ash, placed in an electric furnace and fused at 1200°–1400° C. The product is removed, cooled, and ground. The powder is soluble in a 2% solution of citric acid.—J. H. J.

Straw and other vegetable substances; Treatment of — for manurial purposes. E. H. Richards, Harpenden, Herts. Eng. Pat. 113,571, Aug. 24, 1917. (Appl. No. 12,186 of 1917.)

STRAW is mixed with chalk and placed in a horizontal cylinder of wire netting which can be rotated. The lower part of the cylinder dips into a trough containing water to which chalk and a culture of *B. lactis aerogenes* and *B. azotobacter* have been added. The apparatus is maintained at about 25° C. and the cylinder rotated from time to time. Fermentation is allowed to proceed for some weeks until the pentosans have been destroyed. The mass is then transferred to a tank with a conical bottom, and excess of water and a small quantity of liquid manure are added. The temperature is

maintained at 25°–30° C. by means of a heating coil in the bottom of the tank. When the mass has become liquefied, dry material from the first part of the process is added to absorb the liquid, and the product is raised by an endless lift from the tank. It may be used as a manure directly or after filter-pressing.—J. H. J.

Leather waste; Production of a nitrogenous fertiliser from —.

R. P. Rose, Pittsburgh, Pa. U.S. Pat. 1,255,643, Feb. 5, 1918. Date of appl., July 31, 1914.

LEATHER waste is hydrolysed with dilute sulphuric acid and 1% of an oxidising agent under a steam pressure of 50 lb. per sq. in.—J. H. J.

Superphosphate; Process of making —.

H. Blumenberg, jun., Los Angeles, Cal., Assignor to H. F. Stewart, South Pasadena, Cal., F. Blumenberg, New York, and G. D. Robertson, Los Angeles, Cal. U.S. Pat. 1,255,829, Feb. 5, 1918. Date of appl., Oct. 16, 1917.

GROUND calcareous phosphate material is mixed with acid hydrocarbon sludge, and heated until all the volatile matter is driven off and the residual carbon is left in a finely divided state. The mass is then heated with ground calcareous phosphate rock. The product contains acid calcium phosphate, gypsum, and finely divided carbon, and has fertilising properties.—J. H. J.

XVII.—SUGARS; STARCHES; GUMS.

Plant juices; Preservation of — for determination of sugar content. D. O. Spriestersbach. J. Amer. Chem. Soc., 1918, 40, 431–436.

THE preservation of sweet juices for subsequent analysis requires an agent which will not only prevent fermentation but also inversion, and at the same time will not interfere with the usual analytical processes. Good results are obtained with toluene and potassium mercuri-iodide combined, and it is possible that mercuric nitrate may even be better. A definite volume of the juice is neutralised with calcium carbonate, boiled, mixed with 2 grms. of anhydrous sodium carbonate per litre and also with the preservative, and then made up to the original volume again.—J. C. W.

Sugar solutions; A special "nomon" for calculating the purity of —. A. F. Blake. Intern. Sugar J., 1918, 20, 73–78.

IN order to obviate the calculation involved in determining the purity of mill juices and other liquors from the density and the polarisation, the so-called "nomographic reckoner" devised by H. G. Deming (J. Amer. Chem. Soc., 1917, 39, 213), which enables one to obtain almost instantly results to four figures with an error of one unit in the last place, may be used with advantage. Instead of the general series of scales as originally published, the author has compiled a special series adapted to the calculation of the purity value, in which unnecessary data are eliminated, the exponents expressed clearly with decimal points properly placed, and the ranges set forth for the greatest accuracy and ease of operation.—J. P. O.

White sugar and molasses; Method for the manufacture of —. E. Haddon. Bull. Soc. Chim. de Maurice, 1917, 8, 45–47. Intern. Sugar J., 1918, 20, 88–89.

SYRUP is boiled to grain, and the resulting masse-cuite centrifuged with the addition of a little poor after-product, whilst the sugar obtained is mixed either with rich after-product or with syrup and affined in small centrifugals. The after-product from this affining treatment is diluted to 30° B.

(sp.gr. 1.262) and sulphited, being subsequently used as syrup; and the poor after-product from the first centrifuging is similarly diluted and sulphited, being afterwards boiled to grain and treated in crystallisers, yielding sugar and molasses. Before centrifuging it, some molasses at 30°–35° Brix is added to facilitate the operation, and the second sugar obtained is mixed with that from the first centrifuging, the whole being affined at the same time in small centrifugals. This process is claimed to be superior to so-called "double turbinage" in that the yield is higher and there is no repeated returning of after-products to increase the viscosity of the products.

—J. P. O.

Water: Determination of — in molasses and other sugar factory products by the distillation method. T. van der Linden, M. Kauffman, and F. Leistra. *Archief Suikerind. Ned.-Indië*, 1917, 25, 951–962. *Intern. Sugar J.*, 1918, 20, 89–90.

The direct determination of the water in cane-molasses by distillation with xylol gives very satisfactory results, provided a certain rate of distillation is observed; if heating be prolonged some decomposition of the product with the formation of water occurs. It is necessary to make a "meniscus correction" in measuring the volume of water passing over (this amounted to 0.16 c.c. under the conditions obtaining, xylol and not air being above), and also a correction for loss of water, either by volatilisation or absorption by the liquid distilled (for the apparatus used this was found to be 0.3 c.c.). Fifty grms. of the sample of molasses or other product with 350 c.c. of xylol are placed in a copper distillation flask connected with an upright condenser, the lower end of which discharges into a 250 c.c. measuring cylinder, graduated to twentieths of a c.c. Heating is so regulated that about 100 c.c. of distillate passes over in $\frac{3}{4}$ hour; after this the distillation is accelerated, so that in the fourth $\frac{3}{4}$ hour another 100 c.c. distils over; the receiver is removed immediately when 200 c.c. has been collected. Other volatile immiscible liquids, as benzene, toluene, kerosene, and mixtures of these, gave less satisfactory results.—J. P. O.

Acetic acid and its compounds: The sugar factory as a source of supply for —. P. Coxon. *Intern. Sugar J.*, 1918, 20, 70–71.

It is suggested that the bagasse of cane sugar factories might be used as a gas producing fuel in a standard producer, the gas being burnt under the boilers after the separation of its by-products by condensation and washing. In the case of factories operating with a surplus of bagasse the latter might be submitted to destructive distillation for the preparation of calcium acetate and acetone.

—J. P. O.

PATENT.

Cane-juice filler: Automatic —. B. Salinas y Souza, Assignor to A. C. Smith, Habana, Cuba. U.S. Pat. 1,251,160, Jan. 22, 1918. Date of appl., Mar. 23, 1916.

A WIDE, slightly tapering, rotary, tubular screen is mounted with its axis horizontal. Juice is introduced at the narrower end, and the solid matters retained by the screen travel towards the wider end and are there discharged. The rotation of the screen is effected by the weight of the inflowing juice, the latter being delivered into buckets, a ring of which is mounted on the screen inside its narrower end. These buckets discharge their contents into the body of the screen when in their lowest position.—J. H. L.

XVIII.—FERMENTATION INDUSTRIES.

Hops; Behaviour of the bitter substances of — during wort boiling. W. Wöllmer. *Z. ges. Brauw.*, 1917, 40, 372.

THE bitter flavour of hopped wort and beer is attributed chiefly to the α -resin, humulone, or its transformation products. The β -resin, lupulone, has a less intense flavour, dissolves less readily in wort, and has a much greater tendency to separate from solution with the proteins coagulated during wort boiling. Humulone also separates to some extent with the coagulated protein, so that the more of the latter a wort contains the greater will be the loss of bitter flavour. During wort-boiling both resins undergo, more or less, transformation into more soluble products of intensely bitter flavour. In the case of humulone, the transformation is favoured by low wort acidity, hence relatively alkaline brewing waters tend to give beers of very bitter flavour. The corresponding transformation of lupulone depends more on the presence of air than on the reaction of the wort. (See also this *J.*, 1916, 648.)—J. H. L.

Yeast: Action of arsenic compounds on —. F. Boas. *Z. Gärungsphysiol.*, 1917, 6, 1–12. *Z. ges. Brauw.*, 1917, 40, 199.

FROM experiments with sodium and potassium arsenates and sodium meta-arsenite it is concluded that the sensitiveness of living yeast towards these compounds varies considerably according to the type of yeast and its physiological condition and also to the temperature. Low temperatures accentuating the toxic action. Yeast appears to be capable of recovering from the toxic influence of quantities of arsenic compounds which at first inhibit both reproduction and fermentation. Sodium meta-arsenite retards fermentation. In media containing nitrogenous nutriment the initial toxic influence of arsenates on the zymase of living yeast may become transformed, after some hours, into a pronounced stimulating action. (For the influence of arsenates on fermentation by yeast juice see Harden and Young, this *J.*, 1911, 705.)—J. H. L.

Yeast from thin beers: Microscopic appearance of —. H. Will. *Z. ges. Brauw.*, 1917, 40, 209–211, 217–220.

YEAST crops obtained in the production of bottom-fermentation "war-beers," from worts of 3–6 gravity, were found to show signs of imperfect nutrition. The yeast deposited in the young beers during storage was in better condition, and might be used in pitching. Yeast employed for such thin worts should be periodically refreshed by cultivation in a small quantity of wort of high gravity.—J. H. L.

Beer: De-ionisation of iron in wort and —. A. Reichard. *Kolloid-Zeits.*, 1917, 20, 39–46. *Z. ges. Brauw.*, 1917, 40, 231.

BEER left in contact with iron for 24 hours in presence of air, reacted positively to direct tests for iron in the ferrous and ferric states, but no longer did so after being shaken to remove carbon dioxide. Subsequent addition of hydrochloric acid restored the iron present to its normal reactive state. A similar masking of small quantities of iron in wort or beer may take place whenever the liquid contains suspended matters, e.g., substances coagulated by heating, gluten particles formed on chilling, or even dead yeast cells. Particularly effective in this respect are the particles which separate from beer as the result of intimate contact with air, and which are often so minute as to be detected only by their "Tyndall effect." In all these cases dissolved iron tends to be adsorbed by the suspensoid

matters, and thereupon ceases to respond to the usual tests except after treatment with acid.

—J. H. L.

Beer; Influence of shaking on the biological stability of — H. Will. Z. ges. Brauw., 1917, 40, 249—252.

THE results of some experiments on the effect of shaking on beer in bottles, indicate that when there is some air in the bottles agitation may hasten the appearance of cloudiness or turbidity due to the development of wild yeasts. In the complete absence of air, shaking appears to have little or no influence on the period during which the beer remains bright.—J. H. L.

Saccharin; Non-decomposition of Peligot's during alcoholic fermentation. Some optical properties of this saccharin. H. Pellet. Bull. Assoc. Chim. Sucr., 1917, 34, 327—330.

CANE molasses diluted ten-fold was treated with a small quantity of Peligot's saccharin (see Berichte, 1880, 13, 196) and fermented by a quantity of yeast equal to that of the sugar present; the rotatory power of the fermented liquid indicated that no destruction of the saccharin had occurred. The rotatory power of Peligot's saccharin ($[\alpha] = +93.5$, according to Peligot) is greatly reduced in presence of basic lead acetate and even entirely annulled by a sufficient excess of the latter, but it is restored to its normal value after acidification with hydrochloric acid. Contrary to the statement of Cuisinier, the rotatory power of the saccharin is not modified in solutions containing 10% of acetic acid. The treatment described by Muller (this J., 1916, 858), which destroys dextrose, levulose, glucose, arabinose, xylose, and mannose (but not raffinose), reduces the rotatory power of Peligot's saccharin by about one-third, or more if the heating is prolonged beyond 15 mins.—J. H. L.

Wines; New methods of determining the concentration of hydrogen ions in acid liquids; application to — M. Duboux. J. Chim. Phys., 1917, 15, 473—501.

THE methods of determining hydron concentration based on catalysis of sucrose hydrolysis (cp. Paul, this J., 1915, 1150), or of the decomposition of ethyl diazoacetate (Fränckel, Z. physik. Chem., 60, 202) are tedious and require considerable skill. The second method is much more sensitive than the first, and has the further advantages that it can be applied to darkly coloured liquids and at ordinary temperatures. The hydron concentration in liquids like wine and beer cannot be calculated from a single determination of electrical conductivity owing to the presence of conducting salts. If the progressive change in the conductivity of a wine in the course of neutralisation is investigated, by means of a series of conductivity determinations after addition of successive increments of alkali, and represented as a curve, the original hydron concentration may be found approximately by a graphical method. It is shown, however, that more accurate results may be obtained by diluting the wine with four volumes of water, and determining the conductivity before and after addition of half the volume of standard alkali required for neutralisation (to litmus paper), the results being calculated with the help of certain factors which are given in tables. The results for 30 wines show an average error of 5% when compared with those by the diazoacetate method, which is regarded as the best standard. It is claimed that determinations by the new method can be completed in ten minutes, and that the principles on which the method is based could be applied to other liquids of fairly uniform composition.—J. H. L.

Soy ("shoyu"); Yield of products in the preparation of Japanese — A. Kinoshita. Kōgyō-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1917, 20, 1121—1112.

THE proportions of ingredients employed are as follows:—soya beans, 0.5 koku; wheat, 0.5; common salt, 0.5, and water 1.0 koku (1 koku = 180.39 litres). The beans, when washed, steeped, and steamed, gain about an equal amount in weight and volume as compared with the original. The wheat, when perched and crushed, increases to about 1.8 times its original volume and loses about 0.16 of its original weight. The mixture of beans and wheat is transformed into "koji," the yield of koji being about 1.6 by volume and 0.9 by weight. The koji is mixed with a salt solution (sp. gr. 1.143—1.152) and stirred occasionally. When the summer comes, active fermentation sets in and after one year, finished "moromi" is obtained, its weight being 85 kwan (1 kwan = 3.75 kilos.). This moromi is pressed, and the liquor is pasteurised, yielding about 1 koku (180.39 litres) of Japanese soy.—J. F. B.

"Shoyu-moromi" [Japanese soy]; Stimulating actions of neutral salts on the enzymic actions of — T. Tadokoro. Kōgyō-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1917, 20, 1114—1124.

THE enzymic activities of Japanese soy have a very important effect on the formation of its proper odour and taste during fermentation. These activities are very much checked by the presence of a large quantity of common salt, such as is usually added in the preparation of the "shoyu." They may, however, be stimulated either by decreasing the quantity of salt or by increasing the temperature during fermentation. The author has found yet another method whereby the inhibitive effect of the salt may be controlled, by the antagonistic action of other neutral salts. Potassium chloride, aluminium chloride, calcium chloride and magnesium chloride are good antagonistic agents; aluminium chloride and calcium chloride, show a powerful stimulating effect on amylase and pepsin in "shoyu-moromi." Better results are obtained by using a mixture of two or more salts together than with a single salt. When the concentration of common salt is 3N, a beneficial result is obtained by adding 0.0001—0.002% of a mixture of antagonistic salts to the common salt, whereby the enzymic activities of the shoyu-moromi are increased by 20%.—J. F. B.

Mucor Boulard; Influence of different agents on the saccharifying and fermenting powers of — [in distilleries]. Bettinger. Bull. Assoc. Chim. Sucr., 1917, 34, 251—258. (Cp. Grove, this J., 1914, 562.)

EXPERIMENTS made with Mucor Boulard No. 5 (see Fr. Pat. 464,601, this J., 1914, 497) have shown that the development of acidity is greater the larger amount of sugar present and the lower the temperature. The acidity increases also with access of air, for a time, and then diminishes owing to utilisation of the acids by the mould itself. Succinic acid is the only non-volatile acid produced. The volatile acidity is due chiefly to acetic acid, which appears to be formed when the mould is submerged but disappears in surface cultures. Under industrial conditions, i.e., in distillery mashes, added nitrogenous matter at first retards saccharification but later this effect is more than compensated by acceleration of the process. Peptone and asparagine give the best results in respect of saccharification and fermentation by the Mucor. Vegetative growth is also greatly promoted by peptone and to an almost equal extent by asparagine and ammonium phosphate, but ammonium sulphate has a relatively slight

effect on growth or saccharification. The influence of added phosphates on saccharification appears to depend chiefly on the nature of the base present; the calcium and potassium salts, and to a smaller extent the ammonium salt, accelerate saccharification, whilst sodium phosphate has scarcely any effect. Potassium phosphate increases vegetative growth much more than the sodium and calcium salts.—J. H. L.

Pitch: Brewers' —. F. Eckhardt. Z. ges. Brauw., 1917, 40, 273—276, 281—284, 289—291, 297—300, 306—309, 313—317.

THE author deals at length with the characters required in a brewers' pitch, the methods of examination, the changes which resin and pitch undergo on heating, and many practical points in the pitching of casks. The addition of paraffin wax to pitch made from resin and resin-oil improves the quality in several respects; it raises the flash-point, renders the pitch more fluid at temperatures below that of the pitch-kettle, and thus prevents too rapid thickening in the casks and consequent waste of pitch. Paraffin also reduces the loss which pitch undergoes on continued heating. This loss may be considerable when a large surface is exposed; it is due to evaporation of the more volatile constituents, including some of the resin oil, and has the effect of raising the softening point of the pitch and increasing its viscosity. It cannot be entirely prevented, since the resin itself undergoes slow decomposition at the temperatures employed in pitching, and yields, amongst other products, resin-oil and more volatile substances. For this reason a pitch cannot be completely freed, once for all, from volatile matters likely to affect the flavour of beer. If resin is heated under conditions which permit the more volatile decomposition products, but not the resin-oil, to escape, the softening-point of the residual product becomes lowered, and by heating in this way, say at about 300° C., old pitch or resin itself may be converted into a product possessing the physical characters of brewers' pitch made from resin and resin-oil.—J. H. L.

Notes on alcohols [in microscopy]. Garnett. See XXIII.

Yeast: Process for the production of a blended —. J. A. Stevenson, Burton-on-Trent. Eng. Pat. 113,486, Feb. 23, 1917. (Appl. No. 2683 of 1917.)

BREWERS' yeast is washed and freed from bitterness and pressed. This yeast is then re-fermented in a grain wort, 1 lb. of the yeast being used to 2—2½ lb. of wort prepared from grain of 336 lb. standard, of which at least 50% should be malt. Distillers' yeast is also re-fermented in a separate vessel in a similar manner. After re-fermentation, the surplus wort is removed from each yeast and the two yeasts are then blended in the proportion of about 40% of brewers' yeast to 60% of distillers' yeast and finally pressed.—J. F. B.

"Beer": Non-intoxicating — and process of brewing the same. A. Hadley, Bristol. Eng. Pat. 113,560, June 16, 1917. (Appl. No. 8677 of 1917.)

A BEVERAGE closely resembling beer, but containing less than 2% of alcohol, is prepared by boiling a solution of glucose or invert sugar, or both, with hops and yeast, cooling the solution by means of refrigerators, fermenting with brewers' yeast at an initial gravity of about 1016 (6 brewers' lb.), cooling by means of attenuators when the gravity has fallen to about 5 lb., and clarifying the liquid with "finings."—J. F. B.

Cooling plates for continuous-rectification apparatus. Eng. Pat. 105,549. See I.

XIXA.—FOODS.

Milk: New constituents of —. III. A new protein, soluble in alcohol. T. B. Osborne, A. J. Wakeman, C. S. Leavenworth, and O. L. Nolan. J. Biol. Chem., 1918, 33, 243—251.

WHEN caseinogen is separated from milk, it is usually accompanied by another protein. The latter can be extracted from the caseinogen precipitate by treatment with alcohol, in which it is readily soluble. The composition and properties of the new protein are such as to differentiate it from all known types of proteins of vegetable or animal origin. The amount present in milk appears to be too small to be of much technical significance. (See also J. Chem. Soc., Apr., 1918.)—H. W. B.

Butter and margarine; Detection of artificial colouring matters in —. A. E. Parkes. Analyst, 1918, 43, 87.

AFTER the Valenta number has been ascertained, the mixture of fat and acetic acid is treated with a few drops of dilute sulphuric acid and allowed to stand until the fat has separated. The lower acid layer is coloured in the presence of artificial colouring matters; red, orange, and yellow are the most common colours used. Natural butter fat under the same conditions gives a colourless or at times a faint blue or green acid layer, the colour of which fades quickly.—W. P. S.

Inulin: Degradation of — and of the "inulides" in chicory root. B. Geslin and J. Wolff. Comptes rend., 1918, 166, 428—430.

DURING storage the inulin and the "inulides" undergo degradation, the inulin being gradually converted into the more complex inulides and these being converted into the less complex inulides. (See also J. Chem. Soc., May, 1918.)—W. G.

Bread: Process of making —. D. Chidlow, Ridgefield, Conn., Assignor to J. F. and W. S. Strachan, Montreal, Canada. U.S. Pat. 1,255,292, Feb. 5, 1918. Date of appl., Jan. 4, 1917.

THE bread is made from whole grain by first removing the outer skin of the grain without injuring its germinating property. The grain is then germinated, and whilst still moist from the germinating process is crushed to form a dough, which is afterwards baked.—J. H. J.

Bread: Process and machine for making —. D. Chidlow, Ridgefield, Conn., Assignor to J. F. and W. S. Strachan, Montreal, Canada. U.S. Pat. 1,255,293, Feb. 5, 1918. Date of appl., June 12, 1917.

THE bread is made from whole grain which has its outer skin first removed and is then germinated in tanks in presence of liquid, from which it is afterwards separated and conveyed to crushing machines, where it is crushed to a dough in presence of 15%—25% of its weight of the liquid used in the germinating tanks.—J. H. J.

Aerated waters; Manufacture of — J. Wilson, Acreington, Lancs. Eng. Pat. 113,542, Apr. 17, 1917. (Appl. No. 5381 of 1917.)

THE water to be aerated is placed in a closed tank, the charging tube of which is perforated at its lower end with a large number of holes, $\frac{1}{4}$ in. in diameter. The bottom of the tube is closed by a valve. The carbon dioxide used for aerating escapes slowly through the small perforations, the valve being kept closed by the gas pressure during the aeration. When aeration is completed, the pressure in the tank opens the valve, and the water is discharged through the full bore of the tube which is adapted, externally to the tank, to act as a siphon.—J. H. J.

XIXB.—WATER PURIFICATION ; SANITATION.

Water; Colloid-chemical methods for estimating the hardness of — L. Berczeller. Biochem. Zeits., 1917, 84, 149—155.

POSSIBLY a method of estimating the hardness of water might be based on the facts that the surface tension of soap solutions is diminished by addition of alkalis, but increases again on subsequently adding small amounts of calcium or magnesium salts. (See also J. Chem. Soc., April, 1918.) —S. B. S.

Vanadium; Detection of small quantities of — in water. V. L. Meaurio. Anal. Soc. Quim. Argentina, 1917, 5, 185—189.

A SOLUTION of 0.2 gram. of diphenylamine in 100 c.c. of water in presence of hydrochloric acid gives a violet coloration with aqueous solutions of vanadium compounds. The coloration is unaffected by the presence of nitrates, iron, or titanates, and the test will detect the presence of vanadates in solutions of 0.0002% strength. (See also J. Chem. Soc., Apr., 1918.)—A. J. W.

Disinfectant action of quinine alkaloids on pathogenic bacteria. R. Bieling. Biochem. Zeits., 1918, 85, 188—211.

THE alkaloids investigated were quinine, optochine, eucupine, and iso-(etyl-, decyl-, and dodecyl-)hydrocupreines. These have a specific disinfectant action on bacilli of diphtheria, splenic fever, and tetanus. Eucupine and iso cetylhydrocupreine are generally the most effective. (See also J. Chem. Soc., May, 1918.)—S. B. S.

PATENTS.

Water; Process of softening — Water-softening apparatus. G. H. Uecke, Minneapolis, Minn. U.S. Pats. (A) 1,255,358 and (B) 1,255,359, Feb. 5, 1918. Dates of appl., Feb. 19 and Mar. 21, 1917.

(A) A SUBSTANCE which has been used for water softening is regenerated by displacing the water in which it is immersed by a rising column of a regenerating solution which is denser than pure water. The regenerating solution is used at first weak and subsequently strong. (B) The apparatus consists of a tank holding the softening material and of a tank holding a regenerating solution such as brine. There is a pipe connection from the brine tank to the bottom of the softening tank, so that the brine may be applied as a rising column through the softening material. An independent draw-off pipe for the brine is situated at the upper level of the softening material.—J. H. J.

AN account of tests applicable to the alkaloids pseudo-morphine, protopine, tritopine, cryptopine, laudanine, laudanidine, and laudanoline. (See also J. Chem. Soc., Apr., 1918.)—A. J. W.

Ilex paraguayensis [yerba maté] and its mixtures with other varieties of ilex and herbs not containing caffeine; Volumetric method of identifying — A. Sabatini. Anal. Soc. Quim. Argentina, 1917, 5, 192—198.

THE power of caffeine to reduce ferric salts is the basis of a volumetric method for detecting adulteration of *Ilex paraguayensis*, ammonium thiocyanate being employed as indicator.—A. J. W.

Adonis vernatis; Examination of the leaves of — F. W. Heyl, M. C. Hart, and J. M. Schmidt. J. Amer. Chem. Soc., 1918, 40, 436—453.

TINCTURE of *Adonis vernatis*, or false hellebore, has been used in medicine in recent years. The activity is usually assigned to a digitalis-like glucoside, "adonidin," which Merck's factory has placed on the market, obtaining this principle from the root, according to their latest report. A large consignment of leaves, from Leipzig, has now been examined. The tincture is slightly more toxic than digitalis tincture, but no appreciable quantity of adonidin or any glucoside is present. Most of the toxicity is due to an unknown base, precipitable by phosphotungstic acid, whilst considerable quantities of adonitol, which is the pentitol corresponding with ribose, are present as well. (See also J. Chem. Soc., May, 1918.)

—J. C. W.

Oxalyl chloride as a reagent in organic chemistry. II. Preparation of aromatic acid anhydrides. Reaction with alcohols. R. Adams, W. V. Wirth, and H. E. French. J. Amer. Chem. Soc., 1918, 40, 424—431.

A VERY good method for the preparation of aromatic acid anhydrides consists in adding oxalyl chloride (1.2 mol.) to a boiling benzene solution of the acid (2 mols.). Examples are given. Just as phenols react with oxalyl chloride in the presence of pyridine at 0° C. to give oxalates, so primary and secondary alcohols give these esters in 50% yields on an average. Tertiary alcohols scarcely react at all. The preparation of oxalates of such complicated alcohols as benzooin and piperonoin may therefore be achieved. (See also J. Chem. Soc., May, 1918.)—J. C. W.

Acetic, propionic, and butyric acids; Determination of — R. D. Crowell. J. Amer. Chem. Soc., 1918, 40, 453—460.

THE method depends on the fact that most of the butyric acid, and some propionic acid, can be extracted by means of kerosene after saturating the solution with a mixture of calcium chloride and a little potassium chloride. (See also J. Chem. Soc., May, 1918.)—J. C. W.

"White precipitate"; Preparation, properties, and analysis of — I. M. Kolthoff. Pharm. Weekblad, 1918, 55, 208—218.

A COMPARISON of the methods for preparing "white precipitate" given in the Dutch, German, English, Belgian, Swiss, and U.S. Pharmacopœias. The author is of opinion that the Dutch method is the most satisfactory.—A. J. W.

PATENTS.

Acetic aldehyde [from acetylene]: Manufacture of —. H. Dreyfus, Basle, Switzerland. Eng. Pat. 105,064, Mar. 6, 1917. (Appl. No. 3272 of 1917.) Under Int. Conv., Mar. 6, 1916.

ACETYLENE, freed from impurities such as hydrogen sulphide, hydrogen phosphide, and ammonia, is passed under an increased pressure of about 0.5 atmos. into dilute sulphuric acid containing a compound of mercury, *e.g.*, the oxide, under the following conditions: The solution contains between 10 and 15% total acid and between 1 and 10% (preferably between 3 and 6%) of mercury, the compound having been brought completely into solution by heating the liquid; the acetylene is introduced with strong agitation between 25° and 40° C., slowly at first until the mercury compound precipitated has become grey or greyish-black, and then as rapidly as possible, but avoiding non-absorption; the acetaldehyde formed is distilled off at intervals by raising the temperature to not above 50°–60° C.; the temperature is then reduced again for further absorption, and the process repeated until the absorbing power of the solution has diminished considerably, when the solution is heated above 60° C. to distil off the last traces of acetaldehyde. The mercury residue may be regenerated by treatment with oxidising agents. A suitable absorption apparatus consists of a cylindrical iron vessel, *e.g.*, of 1000–5000 litres capacity, having its inside covered with lead which is treated by heating with sulphuric acid, and, preferably, an oxidising agent, *e.g.*, nitric acid, thus forming a layer of compounds of lead which protects the lead against amalgamation with the mercury and does not dissolve in the absorbing liquid. The stirrer is covered with lead treated in a similar manner. For heating the solution, the apparatus may be provided with a double bottom, with a tank or bath, or pipes of lead treated as above may be introduced into the interior. Yields of 90–95% or more of acetaldehyde can be obtained from the acetylene introduced, amounting to 5–10 times or more the weight of mercury compound employed.—L. A. C.

Physiologically active substance and new compounds containing nitrogen from ovaries, corpus luteum, or placenta: Manufacture of new —. O. Inray, London. From Soc. Chem. Ind. in Basle, Switzerland. Eng. Pat. 113,311, Feb. 13, 1917. (Appl. No. 2151 of 1917.)

PHYSIOLOGICALLY active hormones can be extracted from the tissue of the ovaries, *corpus luteum*, or placenta by several methods, as illustrated by the following example: Pieces of human placenta are dried in a vacuum at a low temperature and powdered, and 5000 grms. of the product extracted with ether or a similar solvent in a continuous extraction apparatus. The solvent is evaporated off and phosphatides precipitated from the residue by the addition of four times its volume of acetone. The liquid separated from the precipitate is freed from acetone in a vacuum. The residue is mixed with cold methyl or ethyl alcohol (*e.g.*, about half a litre) and the insoluble portion (the greater part of

the cholesterol and its esters) separated. The alcohol is evaporated off from the filtrate and the residue purified by fractional distillation under high vacuum. Under a pressure of 0.06 mm. of mercury, a mixture of hormones and cholesterol and its esters distils over between 190° and 210° C. This is purified by further treatment with cold alcohol (*e.g.*, 100 c.c.), and redistillation. The product is a light viscid oil containing only carbon, hydrogen, and oxygen, and showing the typical reactions of cholesterol. Analysis gave C=81.33–81.62%, H=11.32–11.49%. It is not soluble in water, but is absorbed by the colloidal aqueous solution of the phosphatides. The substance promotes the growth of the uterus, of the ovaries, of the oviducts, and of the vagina, and increases the secretion of the mammary glands. The phosphatides isolated appear to be pentamino-diphosphatides; they react with permanganate as unsaturated compounds and contain nitrogen and phosphorus in the proportion of 5:2. They are distinct from the substances extracted from the *corpus luteum* as described in Eng. Pat. 10,877 of 1915 (this J., 1916, 943).—L. A. C.

Quinine group; Manufacture of therapeutically valuable compounds of the —. O. Inray, London. From Soc. of Chem. Ind. in Basle, Switzerland. Eng. Pat. 112,974, Jan. 29, 1917. (Appl. No. 1441 of 1917.)

AN alkaloid of the quinine group or a derivative thereof is allowed to interact in molecular proportions with CC-diallylbarbituric acid or a CC-allylalkylbarbituric acid in the form of the free acid or a salt, in presence or absence of a suitable solvent or diluent, when therapeutically valuable compounds are produced.—F. W. A.

Arsenobenzene derivatives: Preparation of aqueous solutions of —. A. Mouneyrat, Paris. Eng. Pat. 112,984, Feb. 1, 1917. (Appl. No. 1650 of 1917.)

STABLE aqueous solutions of arsenobenzene derivatives are obtained by dissolving their soluble salts in aqueous solutions of reducing sugars, such as glucose (dextrose), levulose, mannose, galactose, etc., contained in bottles filled with nitrogen; the solutions are preserved in sealed capsules in absence of light, if necessary with addition of local anaesthetics. The presence of these reducing substances avoids the oxidation of the arseno compound, with the resulting increased toxicity. The use of dextrose solutions permits of the administration by the intra-muscular method.—F. W. A.

Rendering liquids radio-active; Means for —. O. A. Elias, London. Eng. Pat. 113,483, Feb. 22, 1917. (Appl. No. 2600 of 1917.)

A CARTRIDGE or other receptacle made of cotton or other absorbent material which has been treated with a radio-active salt, is rendered impervious to water by means of a coating of varnish consisting of a condensation product of formaldehyde and phenol in equimolecular proportions dissolved in alcohol. After stoving for 2 hours at a suitable temperature, the cartridge is ready for introduction into the bottle of aerated water, etc., and is preferably attached to the glass tube of a siphon bottle. A coating of fluorescent zinc sulphide may be applied to the cartridge to indicate the presence of the radioactive emanation by being made luminous.—C. A. M.

Treating liquid [to produce colloidal tungstic oxide]; Method of and apparatus for — for curative and therapeutical purposes. W. S. Simpson, Westminster. Eng. Pat. 113,505, Mar. 5, 1917. (Appl. No. 3244 of 1917.)

DISTILLED water or other liquid is exposed to the action of the light and emanations from an arc

struck between a pair of tungsten electrodes. The tungsten is slowly converted into tungstic oxide (WO_3) in such a fine state of division that it remains in permanent suspension in the liquid. The apparatus consists of a casing in the lower part of which is a circular opening having walls extending above and below the bottom of the casing, and under which is placed the arc feeding mechanism holding the tungsten electrodes. Inside the casing and above the arc is a hollow vertical spindle provided at its lower end with a hollow circular perforated cup and connected at its upper end with a reservoir. The spindle is rotated by a motor which also drives a circulating pump. The spindle on being revolved causes a film of liquid coming from the reservoir to be propelled by centrifugal force against the sides of the casing and it flows down forming a curtain of liquid directly over the arc. From the bottom, the liquid is pumped back to the reservoir and is continuously circulated until sufficiently impregnated, when it is drawn off. It may then be aerated. A current of fifteen amperes and a flow of ten galls. per hr. gives a satisfactory result.

—L. A. C.

Isovaleric acid; Manufacture of derivatives [esters] of —. G. B. Ellis, London. From Chem. Fabr. von Heyden A.-G., Radebeul, Saxony. Eng. Pat. 113,983, Dec. 9, 1916. (Appl. No. 17,759 of 1916.)

ESTERS of isovaleric acid with hydroxy acids of the fatty series (*e.g.*, glycollic acid, lactic acid, or those containing an aryl group, such as mandelic acid) are prepared by treating the fatty acids with isovaleric acid (preferably in the presence of dehydrating agents), or with isovaleric anhydride or chloride, or by treating salts of isovaleric acid with the halogen-fatty acids or their salts. Instead of isovaleric acid and its derivatives, halogen-isovaleric acids (especially α -bromoisovaleric acid) may be used. The esters may be neutralised with inorganic or organic bases, *e.g.*, sodium or calcium carbonate, morphine, quinine, etc. Methods of preparation of isovalerylinactive-mandelic acid, both from isovaleric chloride and from isovaleric acid, its calcium and quinine salts; of isovalerylglycollic acid, both from glycollic acid and from sodium chloroacetate, and of α -bromoisovalerylmandelic acid are given as examples.—L. A. C.

Pharmaceutical product [p-benzylphenyl carbamate]. W. Kropp, Elberfeld, Germany., Assignor to Synthetic Patents Co., New York. U.S. Pat. 1,252,452, Jan. 8, 1918. Date of appl., July 21, 1915. Renewed Nov. 23, 1917.

CARBONYL derivatives of phenols containing in the nucleus a substituent, R, which has more than one carbon atom, and having the following general formula: $\text{R.C}_6\text{H}_4\text{.O.CO.R'}$, in which R' is $\text{OC}_6\text{H}_4\text{R}$ or XXX' , X and X' representing hydrogen or an alkyl group, are white, practically tasteless and odourless powders, generally soluble with difficulty in water, and are valuable anthelmintic remedies. *p*-Benzylphenylcarbamate, which separates from alcohol in crystals of m. pt. 144°C ., is particularly claimed.—F. W. A.

Iodine and iodine compounds [tetra-iodohexamethylenetetramine]; Method and means for applying —. G. B. Pegram, New York. U.S. Pat. 1,255,335, Feb. 5, 1918. Date of appl., June 23, 1917.

AN addition compound of iodine and hexamethylenetetramine (tetra-iodohexamethylenetetramine) may be brought into solution by the addition of an alkali halide (potassium iodide) to the solvent. One part of tetra-iodohexamethylenetetramine and three to seven parts of potassium iodide may be mixed to form a dry tablet.—L. A. C.

Acetylsalicylic acid; Process of forming methyl ester of —. L. Thorp, Detroit, Mich. U.S. Pat. 1,255,950, Feb. 12, 1918. Date of appl., Aug. 21, 1916.

ONE equivalent of methyl salicylate and slightly more than one equivalent of acetic anhydride are heated with an alkali acetate to 90° – 100°C . for 10–20 hrs.; alcohol is added, and then hot water until a slight permanent turbidity is produced. The solution is cooled and the product separated by filtration.—L. A. C.

Ethyl-isopropyl-barbituric acid. L. Thorp, Detroit, Mich. U.S. Pat. 1,255,951, Feb. 12, 1918. Date of appl., Jan. 20, 1917.

ETHYLISOPROPYLBARBITURIC acid (ethylisopropylmalonylurea) $(\text{C}_2\text{H}_5)(\text{C}_3\text{H}_7)\text{C}(\text{CO}\cdot\text{NH})_2\text{CO}$, crystallises from water as snow-white crystals, m.pt. 197° – 198°C . It is readily soluble in alcohol or ether; forms salts with the alkali metals which are readily soluble in water; and has a faint bitter taste. The use of the acid and of its sodium salt as hypnotics is claimed.—L. A. C.

Anæsthetic bodies and method of preparing the same. Parke, Davis, and Co., Assignees of L. Thorp, Detroit, Mich., and E. A. Wildman, Indianapolis, Ind., U.S.A. Eng. Pat. 105,744, Feb. 27, 1917. (Appl. No. 2908 of 1917.) Under Int. Conv., Apr. 17, 1916.

SEE U.S. Pat. 1,193,649 of 1916; this J., 1916, 979.

Manufacture of a difficultly soluble complex compound [dimethylphenylbenzyl ammonium zinc chloride] from dimethylaniline, benzyl chloride, and zinc chloride. Eng. Pat. 104,676. See III.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Spectral selectivity of photographic deposits. L. A. Jones and R. B. Wilsey. Phot. J., 1918, 58, 70–81.

IN the usual method of determining plate speeds and other constants, densities are measured visually. As the sensitiveness of ordinary printing materials lies chiefly in the blue, violet, and ultra-violet, if a negative possesses any selective colour absorption its visual densities will not correctly represent its action when used for making prints. The authors consider this subject from the theoretical standpoint and suggest two other methods of measuring the various steps of a sensitometer strip. The values obtained by these when plotted against logarithms of exposures lead to curves and constants similar to the usual "visual" ones, but more nearly representing the actual qualities for printing purposes of the strip or of a negative obtained under the same conditions of development. The constants are, of course, different for different printing materials unless they have the same distribution of spectral sensitiveness. In the first method, that of "photographic density," this is defined as being the logarithm of the ratio of the intensities required to produce equal effects in the same time on the printing material in question (a) through the density being measured and (b) by direct exposure. This method is a null one, avoiding any effect due to the failure of the reciprocity law; it takes no account of the nature of the sensitiveness curve of the printing material. In the second method, that of "effective printing density," this is also considered. In one way of obtaining the effective printing density curve, three preliminary curves are required, the usual

visual sensitiveness curves of the negative and of the printing material and that representing the effect of printing through the negative sensitometer strip on to the printing material: the development of the two latter must be the same. The combination of these three curves gives the effective printing density curve of the negative sensitometer strip for the particular set of conditions employed. The colour coefficient, the ratio of the photographic gamma to the visual gamma, is considered in some detail.—B. V. S.

Photographic intensification; Sensitometry of —. A. H. Nietz and K. Huse. *Phot. J.*, 1918, **58**, 81—93.

THE object of intensification of a negative is to increase contrast for printing purposes, and as the sensitiveness of printing materials is not uniform over the spectrum (including the ultra-violet) the amount of intensification produced by a process is affected by any colour change that may occur in the image. Taking into account the possibility of colour in the original negative as well as after intensification, the authors divide intensifying processes into four general classes according to the relationship between visual and photographic contrasts before and after the process, the essential being only that the photographic or effective printing contrast shall be greater in the intensified negative than in the original. In the experimental work the methods suggested by Jones and Wilsey (see preceding abstract) are adopted. A list of twenty intensifying methods is given and from these a number were selected as representative and examined in more detail as to both visual effect and photographic effect. They include four mercury bleaching methods with various blackening agents, Piper's chromium intensifier, two ferricyanide bleaching methods with sodium sulphide to blacken, Desalme's copper chloride-sodium stannite process, and a permanganate-hydrochloric acid-sodium stannite process. A number of data and curves are given, but it is noted that these refer only to the sensitive materials used and the particular method of development of the negative, since the effect is dependent not only on the intensifying process and the printing material, but also on the character of the original negative deposit. For a similar reason, also, certain intensifiers were not examined, as they are not practicable on the emulsion used. Colour coefficients of various intensifiers, the degree of increased contrast (*i.e.*, the ratios of photographic gammas of intensified and original negatives), and similar factors are also considered.—B. V. S.

Scattering media: Behaviour of — in fully diffused light. H. J. Channon, F. F. Renwick, and B. V. Storr. *Proc. Roy. Soc.*, 1918, **A**, **94**, 222—227. *Phot. J.*, 1918, 121—134.

THE paper deals with the relationships existing between the amount of diffuse light incident on a sheet of diffusing medium, that part of it which is rejected (*i.e.*, returned in opposite directions to the incident light), that which is absorbed, and that which is transmitted, including the case when the source of light is a sheet of diffusing medium in contact with the sheet being examined. A mathematical solution of the problem is presented and experimental data are given in support of the theoretical deductions.—B. V. S.

PATENTS.

Chemical substances [developers, etc.] for use in photography; Preparation of —. A. de Brayer, Paris. *Eng. Pat.* 105,920, Apr. 24, 1917. (*Appl. No.* 5732 of 1917.) Under Int. Conv., Apr. 25, 1916.

IN order to indicate when deleterious substances

such as developers, fixers, etc., have been completely removed from photographic plates, paper etc., by washing, a suitable dye is incorporated with the substance. This dye colours the film and the last traces of colour disappear only with the last traces of the substance. The mixture is prepared as a paste by grinding together with a viscous, water-soluble substance such as glycerin or a solution of sugar, glucose, or alkali silicate.—B. V. S.

Coloured pictures; Production of —. W. F. Fox, Whitestone, N.Y., Assignor to Natural Color Pictures Co., New York. U.S. Pat. 1,256,675, Feb. 19, 1918. Date of appl., Jan. 13, 1917.

Two colour-selection negatives are used. A print is made from one of them and toned bluish-green with Prussian blue. A second print from the other negative is superposed on the same surface in register with the first and toned yellow with a uranium salt or a uranium salt and a basic dye.—B. V. S.

[Photographic] developing composition. T. J. Brewster, Chester, Pa. U.S. Pat. 1,255,508, Feb. 5, 1918. Date of appl., Feb. 25, 1915.

XXIII.—ANALYSIS.

Alcohols [in microscopy]; Notes on —. H. Garnett. *Pharm. J.*, 1918, **100**, 127.

ABSOLUTE alcohol exposed to the air for a few days will absorb several per cent. of moisture, which may seriously impair its usefulness for dehydrating purposes. A rapid method of detecting such deterioration is to mix the alcohol with pure oil of cedarwood, *Juniperus virginiana* (not the so-called thickened oil used for immersion lenses); absolute alcohol will mix in all proportions without cloudiness. Alcohol of 98.2%, which is sufficiently strong for most purposes, also mixes without cloudiness at 15.5°C., but if the temperature is lowered only 1° turbidity is produced. Alcohol which has fallen below this standard of strength may be made practically anhydrous, without distillation, by adding a small quantity of powdered calcium carbide and leaving it for a few days in a warm place; the disagreeable odour of alcohol treated in this way may be eliminated by shaking with a trace of potassium permanganate. Ethyl alcohol may be substituted for methyl alcohol in certain staining solutions, *e.g.*, Delafield's hamatoxylin stain, but for others, such as Leishman's blood stain, methyl alcohol appears to be indispensable. Terpineol, $C_{10}H_{15}OH$, has valuable properties as a clearing agent and may with advantage replace oil of bergamot and oil of cloves. Where desirable, for rapid penetration, it may be diluted with a little xylene.—J. H. L.

Nitrogen: Limitations of the Kjeldahl method of determining —. H. C. Brill and F. Agcaoili. *Philippine J. Sci.*, 1917, 12 A, 261—265.

THE Kjeldahl method of determining nitrogen gives low results with pyridine, piperidine, quinoline, isoquinoline, hydroxyquinoline, pyrrole, and in some cases with nicotine, apparently owing to the formation of sulphonic derivatives which resist decomposition. In the case of most of these compounds it is not possible to obtain the theoretical quantities of ammonia even by increasing the period of heating to 10 hours, and using potassium sulphate with different quantities of mercuric oxide. In the case of pyridine, however, good results may be obtained by the Gunning-Arnold modification by continuing the heating for a considerable time after the solution becomes clear. When mercury is used it is necessary to precipitate it subsequently as sulphide, since otherwise loss of nitrogen may occur owing to the difficulty of decomposing the ammonium mercury compound. If sodium sulphate be substituted for potassium sulphate in the digestion, the results are too low.—C. A. M.

Chlorides: Titration of — by Volhard's method. I. M. Kolthoff. *Z. anal. Chem.*, 1917, 56, 568—576.

WHEN chlorides are precipitated in nitric acid solution by an excess of silver nitrate, the precipitate absorbs about 0.7% equivalent of silver, and a corresponding correction should be made when using Volhard's method. To obtain a sharp endpoint, the mixture of chloride and an excess of silver nitrate should be diluted to a definite volume, shaken, the precipitate allowed to settle, and the excess of silver then titrated with thiocyanate solution in an aliquot portion of the clear liquid; the above-mentioned correction must be applied. Satisfactory results may also be obtained if the titration is interrupted at the first change in colour of the indicator; the mixture is then stirred until the precipitate has collected together, and the titration completed. Addition of ether or other immiscible liquid is not recommended.—W. P. S.

Phosphoric acid. Determination of —. Modification of the citrate method. J. Grossfeld. *Z. anal. Chem.*, 1918, 57, 28—33.

THE hydrochloric acid solution of the sample (fertiliser, ash, etc.) is treated with an excess of ammonium oxalate solution, a few drops of methyl orange solution are added, and saturated ammonium acetate solution is run in until the colour of the indicator changes from red to yellow. The mixture is diluted to 100 c.c., mixed, filtered through a "Kieselguhr" filter (this J., 1916, 1105), an aliquot portion of the filtrate is treated with 5 c.c. of 20% citric acid solution, and the phosphoric acid is precipitated in the usual way as ammonium magnesium phosphate.—W. P. S.

Hydrocyanic acid: Detection and determination of small quantities of —. I. M. Kolthoff. *Z. anal. Chem.*, 1918, 57, 1—15.

THE sensitiveness of the various tests for hydrocyanic acid is as follows, expressed in mgrms. CN per litre of solution: Prussian blue, 2; ferric thiocyanate, 0.1; picric acid, 1; guaiacum, 0.001; phenolphthalein, 0.05; silver, 0.03; iodine-starch, 0.1. (See also this J., 1918, 122 A.) —W. P. S.

Tungsten: Colorimetric estimation of —. Travers. *Comptes rend.*, 1918, 166, 116.

IN the colorimetric estimation of tungsten by titanous chloride, the solution should not contain more than 0.1 gm. of the metal in 100 c.c. and its acidity should not exceed N/10. Vanadium, phosphorus, and molybdenum must be removed before the method can be used. (See further J. Chem. Soc., May, 1918.)—W. G.

Thorium: Oxidimetric determination of — precipitated as oxalate. F. A. Gooch and M. Kobayashi. *Amer. J. Sci.*, 1918, 45, 227—230.

THORIUM may be determined by titrating its oxalate with permanganate solution. The thorium oxalate should be precipitated by adding the thorium salt solution to the oxalic acid solution; in the reverse procedure, there is a tendency to the formation of basic thorium compounds, especially in hot solutions, and the titration results are less reliable. (See also J. Chem. Soc., May, 1918.)—W. P. S.

Metals: Machine for testing the hardness of —.
D. Chattaway, Farsley, Yorks. Eng. Pat. 114,126, Dec. 8, 1917. (Appl. No. 18,215 of 1917.)

THE specimen to be tested is mounted on a table forming the head of a vertical screwed spindle, so that it may be adjusted vertically. The hardened ball which is forced against the article to be tested is mounted on a spindle sliding vertically in an arm projecting horizontally from the upright standard of the machine, and the spindle is attached to one end of a lever fulcrumed on a knife edge. The other end of the lever is connected by a vertical link to the short arm of the main beam of the machine, which rests horizontally on a knife edge at the top of the upright standard. A weight is adapted to be moved along the beam by means of a suitable hand wheel and screw, so that the load on the ball may be increased uniformly from zero to a maximum. The hardness of the specimen is estimated from the diameter of the indentation produced in it.—W. F. F.

Hardness-testing machine. F. L. Morse, Ithaca, N.Y. U.S. Pat. 1,255,913, Feb. 12, 1918. Date of appl., June 26, 1914.

IN a machine for measuring hardness, the lower abutment for supporting the specimen is mounted in a recess in a frame and supported by a spiral spring. An indenting tool to which pressure is applied, is mounted so as to slide in the upper part of the frame. The upper and lower portions of the frame are connected by guide-bolts, one of which is hollow, and a cylinder connected rigidly to the spring-pressed abutment slides within the bolt. A piston fitting in the cylinder is carried by the indenting tool so that the relative movement of the piston in the cylinder is a measure of the indentation produced in the specimen. The cylinder contains a heavy liquid at the bottom and a lighter liquid at the top, and a measuring gauge is connected to the heavier liquid to indicate the displacement. Another indicating device is provided to measure the movement of the abutment relatively to the frame, which is proportional to the force exerted on the specimen.—W. F. F.

Laboratory [steam-generating] apparatus. K. P. McElroy, Washington, D.C. U.S. Pat. 1,254,048, Jan. 22, 1918. Date of appl., May 16, 1917.

WATER is constantly supplied to a receptacle closed at the bottom and having a concentric vertical overflow tube, the inlet of which is near the top of the receptacle. A tube extends horizontally from the bottom of the receptacle and has two substantially right-angled bends in a vertical plane, so that its free end is inclined slightly upwards at such a height that the water level is in this part of the tube. Heat is applied by a burner to the water in the inclined tube and the steam escapes at the open end.—W. F. F.

Filter-funnel. F. S. Hawken, St. Louis, Mo. U.S. Pat. 1,257,956, Feb. 26, 1918. Date of appl., Apr. 30, 1917.

IN a filtering funnel the upper part of the interior surface of the cone is smooth so that the filter paper adheres to it, and the lower part of the cone is made with thinner walls so that an internal shoulder is formed at the junction. The lower part is roughened internally and provided with grooves and projections just below the shoulder.—W. F. F.

Radiation pyrometers. A. Hilger, Ltd., and T. R. Merton, London. Eng. Pat. 113,865, Mar. 31, 1917. (Appl. No. 4686 of 1917.)

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Brownell. Apparatus for drying, etc., materials. 5629. Apr. 2. (U.S., Apr. 6, 1917.)

Donald. Kilns. 6233. Apr. 12.

Gieve. Device for blending or mixing. 6172. Apr. 11.

Lonsdale. Non-conducting composition for insulating pipes, etc., in chemical works. 5919. Apr. 6.

Ransome and Marles Bearing Co., and Marles. Grinding machines. 5651. Apr. 3.

Schär. Grinding-mills. 6305. Apr. 13. (Switzerland. May 3, 1917.)

COMPLETE SPECIFICATIONS ACCEPTED.

105 (1917). Van Musschenbroek. Drying wet or watery materials, especially fruits and vegetables. (114,442.) Apr. 17.

5915 (1917). Major. Distillation or evaporation of liquids. (114,353.) Apr. 10.

8697 (1917). Kirkham, Hulett, and Chandler, and Hersey. Apparatus for effecting intimate contact between liquids and gases. (114,370.) Apr. 10.

11,459 (1917). Van Iterson and Kuypers. Cooling-towers of reinforced concrete. (108,863.) Apr. 17.

17,974 (1917). Braam. Apparatus for use in preparing solutions of gases. (111,558.) Apr. 17.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Allgem. Ges. f. Chem. Ind. 6067. See III.

Beswick. Gas generators or producers. 5974. Apr. 8.

Cross, and Latham, Harris, and Co. Treating or refining petroleum. 5764. Apr. 3.

Davis. Coke-ovens, and carbonisation of coal. 5597. Apr. 2.

Freear and Schauer mann. Liquid fuel. 5805. Apr. 4.

Harger. 5594. See VII.

Helps. Manufacture of a producer-gas for lighting, heating, and power. 5701. Apr. 3.

Pearson and Son, and Smith. 6280. See III.

Rew. Retorts for gas production. 6077. Apr. 10.

Rew. Retorts. 6313. Apr. 13.

Simpson. Heating flues of chambered ovens or retorts for producing gas and coke or fuel. 6230. Apr. 12.

Ten Bosh. Removing water from peat. 5692. Apr. 3. (Holland. Feb. 21.)

Walker. Gas-generating and heating apparatus. 5736. Apr. 1.

West and Wold. Charging retorts or chambers for destructive distillation of carbonaceous materials. 5788. Apr. 4.

COMPLETE SPECIFICATIONS ACCEPTED.

4873 (1917). Dreffin and Flinn. Gas-producing and consuming plants. (114,474.) Apr. 17.

5037 (1917). Macintosh and Hunt. Manufacture of coal gas, etc. (105,563.) Apr. 17.

5272 (1917). Euler. Gas generators. (114,491.) Apr. 17.

8789 (1917). Anderson. See III.

16,290 (1917). Thuman (Chrisman). Gas wash-boxes. (114,397.) Apr. 10.

19,019 (1917). Boorne. Wet carbonising apparatus and process. (114,603.) Apr. 17.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Allgem. Ges. f. Chem. Industrie. Continuous and uniform treatment of hydrocarbons with sulphurous acid. 6067. Apr. 9. (Ger., Mar. 21, 1917.)

Pearson and Son, and Smith. Treatment of coal-tar pitch, etc., for production of fuel. 6280. Apr. 13.

Thorp and Thorp. Refining benzol, etc. 6306. Apr. 13.

COMPLETE SPECIFICATIONS ACCEPTED.

3948 (1917). Thompson (Reilly). Process and apparatus for distilling coal tar or the like. (114,453.) Apr. 17.

8789 (1917). Anderson. Carbonisation of pitch. (114,371.) Apr. 10.

IV.—COLOURING MATTERS AND DYES.

COMPLETE SPECIFICATION ACCEPTED.

4426 (1917). Inray (Soc. Chem. Industry in Basle). Manufacture of disazo dyestuffs for wool. (114,339.) Apr. 10.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Chambers and Hammond. Machines for washing flocks, rags, etc. 5946. Apr. 8.

Chambers and Hammond. Treatment of wool-scouring, etc., liquors containing grease or oil. 6005. Apr. 9.

Cretney, and Latham, Harris, and Co. Treating shoddy refuse from cotton waste. 5659. Apr. 3.

Croll. Manufacture of waterproof paper, etc. 6151. Apr. 11.

Johnston and Sutherland. Degumming or cleansing stalk fibres. 6217. Apr. 12.

Mond. Means for doping aeroplane, etc., fabrics. 5619. Apr. 2.

Zdanowich. Manufacture of cellulose acetates. 5952. Apr. 8.

COMPLETE SPECIFICATIONS ACCEPTED.

4248 (1917). Berglund. Apparatus for washing and airing cellulose and like fibrous materials. (114,456.) Apr. 17.

4991 (1917). Wallace, Marshall, Brown, and Bertrams, Ltd. Removing esparto, etc., from stationary digesters and the like. (114,348.) Apr. 10.

5406 (1917). Williams. Waterproofing composition for textile materials, etc. (114,494.) Apr. 17.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Larivei. Textile-yarn lustreing machines. 6016. Apr. 9.

Larivei. Machinery for dyeing, etc., textiles. 6017. Apr. 9.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Craig. 5653. See X.

Darrasse. Catalyser for production of oxy-chloride of carbon, etc. 6062. Apr. 9. (Fr., Apr. 23, 1917.)

Harger. Manufacture of hydrogen. 5594. Apr. 2.

Heap and Newbery. Manufacture of anhydrous chlorides. 5596. Apr. 2.

Maxted. Synthetic production of ammonia. 5741. Apr. 4.

Partington and Rideal. Oxidation of ammonia. 6112. Apr. 10.

Passmore. Utilisation of nitre cake. 6063. Apr. 8.

Taliani. Catalytic oxidation of ammonia. 5979. Apr. 8.

Titan Co. Aktieselskab. Titanium products. 6111. Apr. 10. (Norway, May 21, 1917.)

Wyld. Apparatus for distilling or treating ammoniacal liquors, etc. 6122. Apr. 10.

COMPLETE SPECIFICATIONS ACCEPTED.

5683. (1917). Dreyfus. See XX.

6009 (1917). Potter and Co., and Potter. Manufacture of sulphate of soda from chrome residues. (114,501.) Apr. 17.

6551 (1917). Comment. See XIII.

7213 (1917). Norske Aktieselskab for Elektrokemisk Industri. Manufacture of titan acid. (108,850.) Apr. 17.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Calcott, Pickard, Sherlock, and Smith. Cement for repairing ceramic articles, glassware, etc. 5821. Apr. 5.

Levi. Refractory substances. 5592. Apr. 2.

Mississippi Glass Co. Light-refracting glass. 5715. Apr. 3. (U.S., Aug. 17, 1917.)

IX.—BUILDING MATERIALS.

APPLICATIONS.

Bravin. Concrete. 5881. Apr. 5.

Hickson. Cement and process of manufacturing same. 5725. Apr. 3.

Kelsey. Waterproof preparation for roofing, etc. 6248. Apr. 12.

COMPLETE SPECIFICATION ACCEPTED.

8298 (1917). Scarlett. Cement. (114,527.) Apr. 17.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Annable and Janson. Treatment of ores and mixtures containing scheelite. 5723. Apr. 3.

Annable and Janson. Extraction of tin from its ores. 5858. Apr. 5.

Coles. Rendering aluminium and its alloys more durable. 5710. Apr. 3.

Cooper Co. Alloy. 6097. Apr. 10.

Craig. Recovering potash salts from blast furnaces. 5653. Apr. 3.

Cressey and Cressey. Recovery of metals from dross, skimmings, etc. 5901. Apr. 6.

Downes. Furnaces for melting metals. 5948. Apr. 8.

Ghijssen, and Naaul. Vennootsch. Vitrite Works. Smelting furnaces. 6057. Apr. 9.

Gontermann. Thomas process for producing steel. 5811. Apr. 4. (Ger., Apr. 4, 1917.)

Harvey. Annealing and reheating furnaces, etc. 6119. Apr. 10.

Hunt. Electrolytic treatment of ores. 6101. Apr. 10.

Marks (U.S. Nickel Co.). Separating nickel from nickel-copper mattes. 6193. Apr. 11.

Nelson and White. Manufacture of metallic lead powder and lead paints. 6065. Apr. 9.

Quinan. Production of metals. 6259. Apr. 12.

Ramén. Mechanical roasting furnaces. 6271. Apr. 12.

Verein. Hüttenwerke Burbach-Eich-Düdelingen A.-G. Production of metallic alloys. 6274. Apr. 12. (Ger., June 23, 1916.)

COMPLETE SPECIFICATIONS ACCEPTED.

1388 (1917). Fennell, and British Carbonizing Co. Carburising or case-hardening iron or steel articles. (114,446.) Apr. 17.

2814 (1917). Shiga. Gold alloys. (114,447.) Apr. 17.
 4112 (1917). Hamilton. Manufacture of grey-cast-iron. (114,328.) Apr. 10.
 4746 (1917). Reynolds. Casting steel ingots. (114,466.) Apr. 17.
 6821 (1917). Richmond Gas Stove and Meter Co., and Thompson. Steel furnaces. (114,359.) Apr. 10.
 8225 (1917). Pozzo and Colonnetti. Testing of iron materials. (107,376.) Apr. 17.
 11,307 (1917). Rollason. Melting and de-oxidising mill scale, etc. (114,561.) Apr. 17.
 13,405 (1917). Granberg. Condensers for re-distilling spelter. (112,008.) Apr. 17.
 17,231 (1917). Reid Bros., and Brown. Apparatus for testing the hardness of metals. (114,593.) Apr. 17.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

British Thomson-Houston Co. (General Electric Co.). Insulating materials. 6180. Apr. 11.
 Fleming. Electric furnaces. 6039. Apr. 9.
 Hunt. 6101. *See* X.
 Marconi. Electric accumulators. 5867. Apr. 5. (Italy, Apr. 5, 1917.)
 Sokal (Sokal). Primary batteries. 6059. Apr. 9.

COMPLETE SPECIFICATIONS ACCEPTED.

2838 (1917). Bonora. Primary electric batteries. (114,323.) Apr. 10.
 4886 (1917). Wade (Flanders). Manufacture of storage battery plates and paste therefor. (114,475.) Apr. 17.
 14,933 (1917). Dixon. Electric furnaces. (111,104.) Apr. 17.
 15,722 (1917). Hoyle and Fawcett. Electrodes of electric furnaces. (114,395.) Apr. 10.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Blisey. Compound for washing, cleaning, etc. 6108. Apr. 10.
 Carper and Tulloch. 5635. *See* XIV.
 Chambers and Hammond. 6005. *See* V.
 Feldenheimer and Plowman. Soap or soap derivatives. 6170. Apr. 11.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Britton, and Griffiths Bros. and Co. Resins, and treatment thereof. 5724. Apr. 3.
 Nelson and White. 6065. *See* X.
 New Jersey Zinc Co. Zinc-lead pigments, and method of manufacturing same. 6270. Apr. 12. (U.S., Oct. 26, 1917.)

COMPLETE SPECIFICATIONS ACCEPTED.

6531 (1917). Comment. Preparation of anhydrous sulphide of zinc. (106,489.) Apr. 10.
 15,025 (1917). Morris. Manufacture of a red pigment. (114,581.) Apr. 17.
 18,944 (1917). Akashi. Solid ink. (114,601.) Apr. 17.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATIONS.

Carper and Tulloch. Preparation of solvents for indianrubber and animal fats. 5635. Apr. 2.
 Dunlop Rubber Co., and Macbeth. Rubber-mixing, etc., machines. 5634. Apr. 2.
 Gillott and Marple. Gum driers and solidifiers for rubber, etc. 6086. Apr. 10.
 Jackson (Morgan and Wright). Calendering machines for treating rubber. 5796. Apr. 4.
 Porzel. Treatment of rubber. 5758. Apr. 4.
 Porzel. Vulcanising rubber, etc. 5759. Apr. 4.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Ashley and Parsons. Artificial leather. 5600. Apr. 2.
 Bennert. Utilisation of leather waste. 6050. Apr. 9. (Ger., Apr. 30, 1917.)
 Gilardini. Instantaneous tanning of hides and skins. 5874. Apr. 5. (Italy, Apr. 6, 1917.)

COMPLETE SPECIFICATION ACCEPTED.

6391 (1917). Barclay. Manufacture of leather. (114,358.) Apr. 10.

XVI.—SOILS; FERTILISERS.

COMPLETE SPECIFICATION ACCEPTED.

5119 (1917). Svendsen. Construction of cyanamide and like silos. (114,487.) Apr. 17.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATIONS.

Greville. Malt products. 5674. Apr. 3.
 Greville. Brewing, and manufacture of brewing sugar, etc. 5676. Apr. 3.
 Wardle. Extraction of liquid from yeast cells and its separation from the cellular matter. 6037. Apr. 9.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Andrews. Sea-water evaporators. 5914. Apr. 6.
 Bullot. Preservation of meat, etc. 5793. Apr. 4. (Austral., July 21, 1917.)
 Greville. Treatment of flour. 5671, 5672, and 5673. Apr. 3.
 Greville. Food products containing potatoes. 5675. Apr. 3.
 Ohata. Process of canning. 5894. Apr. 6.

COMPLETE SPECIFICATIONS ACCEPTED.

105 (1917). Van Musschenbroek. *See* I.
 5082 (1917). Lassen and Hjort. Apparatus for purifying and softening water. (114,485.) Apr. 17.
 19,008 (1917). Hyatt and Fellowes. Insecticides. (114,602.) Apr. 17.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Abbott Laboratories. β -Bromoethyl-*p*-nitrobenzoate. 6262. Apr. 12. (U.S., Dec. 21, 1917.)
 Allgem. Ges. f. Chem. Ind. 6067. *See* III.
 Paschall. Substance for treating tuberculosis, leprosy, etc. 5864. Apr. 5. (U.S., May 1, 1917.)

COMPLETE SPECIFICATIONS ACCEPTED.

5683 (1917). Dreyfus. Manufacture of acetic acid from acetic aldehyde. (108,459.) Apr. 10.
 8810 (1917). Soc. Chim. des Usines du Rhône. Production of acetic anhydride and polymerised or non-polymerised acetic aldehyde. (110,906.) Apr. 17.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

Burnett. Manufacture of photographic negative film. 5810. Apr. 4.
 Dubois. Photographic printing. 5931. Apr. 6. (Fr., Dec. 17, 1917.)
 Shiel. Kinematograph films. 6299. Apr. 13.

XXIII.—ANALYSIS.

COMPLETE SPECIFICATIONS ACCEPTED.

8225 (1917). Pozzo and Colonnetti. *See* X.
 17,231 (1917). Reid Bros., and Brown. *See* X.

I.—GENERAL ; PLANT ; MACHINERY.

Refrigerating plants ; Relation between efficiency of — and the purity of their ammonia charge. F. W. Frieichs. Amer. Inst. Chem. Eng., Dec., 1917. J. Ind. Eng. Chem., 1918, 10, 202—212.

AMMONIA refrigerating machines are of two types: absorption machines, in which the ammonia gas is absorbed in aqueous solution and regenerated under high pressure by heating at about 150° C. in a retort or boiler, so that ammonia is liquefied on cooling in the condenser; and compression machines, in which the gas is liquefied by pumping it into the condenser at a pressure of about 250 lb. per sq. in. In both types refrigeration is effected by reversing the liquefied ammonia through an expansion valve into a coil immersed in the cooling liquid. The question of the purity of the ammonia charge is of the highest importance. If substances are present either in suspension or solution which retard the evaporation of the ammonia or the transmission of heat through the walls of the tubes, the efficiency of the machine is greatly impaired. An apparatus is described for measuring the rate of evaporation at constant temperature. It is attached to the discharge nozzle of the transport cylinder and is adapted to draw off 100 c.c. of liquid ammonia and evaporate it by heat derived from a bath of ice-water surrounding a calcium chloride bath in which the apparatus is immersed. The less volatile impurities are collected at the bottom and by making several tests in succession, the cumulative influence of these impurities on the rate of evaporation may be observed. One of the most obnoxious impurities, which may not be in the original ammonia but is always liable to be present in the working machine, is lubricating oil, which coats the coils of the cooling tank and very seriously interferes with the efficiency of the heat transmission. Non-condensable gases constitute another serious source of loss of efficiency, particularly on the compression side of the plant; the pressure required to produce liquefaction increases with the degree of contamination. These gases accumulate in the condenser and can be blown out periodically through a vent cock. Non-condensable gases may also be developed from the lubricating oil at the temperature of the compressor, and an apparatus is described for testing oils in this respect. Impurities, such as acetic acid and acetonitrile, in the ammonia may lead to rapid corrosion of the plant; a small quantity of acetic acid may corrode a large amount of iron since the acid is always regenerated. Details are given of continuous tests made with two refrigerating plants, one using pure ammonia and the other an inferior quality. The former produced 16,862 tons of ice at an ammonia cost of 1.27 cents per ton, while the latter produced only 11,308 tons in the same period at an ammonia cost of 15.16 cents per ton. In addition, the second plant was considerably corroded. The production of permanent gases during working was a special characteristic of the inferior ammonia, necessitating frequent purging through the vent cock; these gases could be ignited and gave a very large flame over a period of 25–30 minutes. Analysis of the volatile carbon compounds present in the two grades of ammonia showed 0.002% (as CO₂) in the pure ammonia and 0.002% in the inferior. The volatile carbon compounds can be concentrated and the ammonia purified by fractional distillation of the liquefied gas; the degree of purity obtained corresponds to the former figure quoted above. In machines of the absorption type, careful attention must be paid to the purity of the distilled water used for absorbing the ammonia; it must be distilled from water freed from suspended organic matters. The

author proposes a method for the estimation of minute quantities of volatile impurities in liquid ammonia, based on the increase of vapour tension which is caused by the presence of volatile impurities. The apparatus consists of two similar barometer tubes enclosed in the same water jacket, which can be heated uniformly. An impure sample of ammonia neutralised with pure sulphuric acid is placed over the mercury in one barometer and a solution of pure ammonium sulphate in the other. The difference in level of the two barometers at various temperatures indicates the relative vapour tensions of the two samples and may be standardised in terms of benzene.—J. F. B.

Thermochemical processes ; Laws of — and of photochemical processes. M. Trautz. Z. anorg. Chem., 1918, 102, 81—129.

THE author summarises his views on the laws of gas reactions, with particular reference to the relation between the velocity constant, heat of reaction, and "heat of activation." The equations and laws deduced for thermochemical reactions are then applied to photochemical reactions. (See also J. Chem. Soc., May, 1918.)—E. H. R.

PATENTS.

Organic chemical reactions ; Process of effecting—. A. M. Aylsworth, and Savings Investment and Trust Co., East Orange, N.J., Eng. Pat. 110,547, Jan. 17, 1917. (Appl. No. 14,152 of 1917.) Under Int. Conv., Jan. 24, 1916.

A BATH of fused sodium nitrite is used for supplying heat to a chamber in which organic chemical reactions are conducted. The salt fuses at about 213° C. and may be heated to 390° C. or even higher without decomposing. The fused salt is a thin fluid so that uniformity of temperature is insured. It is claimed to be superior to a bath of fusible metal. The reaction chamber may be in the form of a coil of tubing through which the reaction mixture is forced.—J. H. P.

Storing, treating, or conveying corrosive liquids or substances ; Apparatus for —. J. Wolf, London. Eng. Pat. 113,992. (Appl. Nos. 2017, Feb. 9, and 2295, Feb. 15, 1917.)

METALLIC vessels are provided with perforated supports spaced apart from the walls around which the resisting lining material is cast or moulded.—W. H. C.

Compression of granular and other substances [e.g., peat]. T. W. S. Hutchins, Middlewich, Cheshire. Eng. Pat. 114,002, Mar. 8, 1917. (Appl. No. 3314 of 1917.)

IN the compression of granular and other substances by extrusion, a horizontal cylinder is provided having an inlet and a feeding hopper at one end. The inlet is controlled by a reciprocating plunger which forces the material towards the discharge nozzle at the other end, and a small secondary reciprocating plunger is provided moving concentrically within the main plunger, which imparts the final compression to the charge and produces a more uniform compression. When the press is used for expressing liquids, e.g., for removing water from peat, a perforated cylinder is used.—W. F. F.

Furnaces ; Gaseous fuel —. A. C. Ionides, jun., London. Eng. Pat. 114,223, Apr. 16, 1917. (Appl. No. 5352 of 1917.)

IN a furnace of the type described in Eng. Pat. 108,701 (this J., 1917, 1086), a series of upright combustion chambers or passages are arranged in or upon the encircling wall of an upright tubular heating chamber. These passages communicate

with the heating chamber by one or more narrow openings and are supplied with a combustible gaseous mixture by jets situated at or near their lower ends. The passages may be spaced equidistantly around the heating chamber and formed in the thickness of the walls.—J. H. P.

[Muffle] furnace. F. W. Steere, Detroit, Mich. U.S. Pat. 1,257,649, Feb. 26, 1918. Date of appl., July 31, 1915.

A MUFFLE furnace is provided with valve-controlled sets of regenerating chambers through which the fuel and exhaust gases are passed alternately, to and from the combustion chamber. The muffle is arranged adjacent to the combustion chamber and is adapted to receive "stock" at one end and discharge it at the other end into a receptacle arranged in a tower into which the exhaust gases from the regenerator also pass. The oxidation of the "stock" is thereby prevented.—W. F. F.

Separators; Pneumatic —. G. W. S. Simpson, London, Eng. Pat. 114,288, Dec. 17, 1917. (Appl. No. 18,737 of 1917.)

The separator comprises a screening surface consisting of a number of louvres arranged to form an inclined plane. The size of the openings between the louvres can be varied. The material to be separated descends this inclined plane against a current of air which carries the smaller and lighter particles between the louvres, whilst the larger particles fall into a shoot and are discharged. The current of air laden with particles is conveyed to a separator of the cyclone type, in which the inlet pipe terminates within a hood in a number of curved outlets adapted to impart a spiral motion to the air within the hood. The hood is contained in a closed hopper from which the dust is discharged, whilst the air is returned to the intake of the blower used for circulating the air. The apparatus is specially applicable to the grading of sand, earths, nitrate caliche, etc.—J. H. P.

Condenser. H. A. Hills, Grand Rapids, Mich. U.S. Pat. 1,256,229, Feb. 12, 1918. Date of appl., July 28, 1916.

AN outer cylindrical vessel containing cooling liquid is open at the top and is provided with condensing tubes fixed in the bottom plate and extending upwards. An inverted conical member is attached below the tube-plate to collect and discharge condensed liquid. The upper ends of the tubes are fixed in a tube-plate of smaller diameter than the cylinder and this plate is surmounted by a conical hood. Vapour to be condensed is supplied to the top of the hood and passes through and over the edges of a perforated rectangular horizontal plate mounted in the hood above the upper ends of the tubes. Cooling liquid is supplied to the bottom of the outer vessel and is discharged at the top.—W. F. F.

Separator; Centrifugal —. F. L. Jefferies, Riverside, Ill., Assignor to Corn Products Refining Co. U.S. Pat. 1,256,697, Feb. 19, 1918. Date of appl., July 21, 1917.

A ROTARY container is provided with a discharge opening in the cover for the lighter constituent of the material treated and also with a discharge duct for the heavier constituent. The inlet branch of this duct extends downwards inside the container near the wall, and the duct passes through the container wall and has a discharge branch also extending downwards. Both discharge openings have a larger cross-sectional area than is required for the quantity of material which normally passes through them.—W. H. C.

Separator; Centrifugal —. M. B. Miller, Long Island City, N.Y., Assignor to Sharples Specialty Co., West Chester, Pa. U.S. Pat. 1,257,515, Feb. 26, 1918. Date of appl., Oct. 10, 1917.

THE separator consists of a rotary vertical bowl having an axial bottom inlet and an unobstructed lower inner portion. A spreader is provided above the inlet and means for "catching and accelerating the revolution" of the contents of the bowl are arranged in its upper part.—W. H. C.

[Centrifugal machines;] Froth-reducing discharge apparatus and process [for —]. M. Leitch and B. R. Wright, Poughkeepsie, N.Y., Assignors to the De Laval Separator Co., New York. U.S. Pat. 1,256,810, Feb. 19, 1918. Date of appl., Oct. 29, 1915.

To reduce froth formation in the discharge of liquid from high-speed centrifugals with an overflow discharge, the liquid is propelled in an outward and rearward direction from the overflow, and the usual thin, flat stream is caused to form a thicker stream without reducing the cross-sectional area, whereby the velocity of the stream and its exposed surface are both reduced. The centrifugal is provided with a number of relatively long discharge weirs, over which the liquid flows in thin streams. A curved discharge passage extending outwards and rearwards, converging in one direction, extends from each weir and is proportioned and arranged to discharge the liquid in a solid stream thicker than at the weir, without increase in the nozzle velocity.—J. H. P.

Liquid-purifier; Centrifugal. —W. G. Howell, Warrenton, Va. U.S. Pat. 1,257,235, Feb. 19, 1918. Date of appl., Dec. 13, 1917.

A HORIZONTAL cylinder mounted on a hollow shaft is divided by a partition into an inner axial chamber and an outer narrow annular chamber. The cylinder is rotated rapidly on the hollow shaft through which the liquid is introduced into the axial chamber. From the axial chamber the liquid passes into one end of the outer annular chamber and the separated solids are collected in pockets formed on the periphery. The clarified liquid is discharged from the opposite end.—W. H. C.

Refrigerating apparatus. W. A. Richter and E. S. H. Baars, Milwaukee, Wis. U.S. Pat. 1,256,730, Feb. 19, 1918. Date of appl., Dec. 29, 1916.

A SUPPORTING frame carries a gas chamber above and an expansion chamber below. A number of compressing cylinders are disposed radially within the gas chamber, the pistons being operated from cams on a central vertical shaft. The gas chamber is surrounded by a condenser which has a conduit communicating with the expansion chamber. Below the expansion chamber, and communicating with it, are vertical cooling coils.—W. H. C.

Evaporating tank. W. E. Fletcher, Tamaqua, Pa., Assignor to Atlas Powder Co., Wilmington, Del. U.S. Pat. 1,257,209, Feb. 19, 1918.

REMOVABLE spur tubes, slightly spaced from each other, are arranged just above the bottom of the tank and extend through flanged ports in the opposite ends of the tank. The ends of the spur tubes are connected by flanged elbows with flanged outlets of a steam manifold, one at each end of the tank. Each elbow is provided with a "bleed pipe," which projects into the adjacent spur tube.—J. H. P.

Evaporating apparatus. C. R. Harris, Assignor to A. P. Campbell, Los Angeles, Cal. U.S. Pat. 1,257,854, Feb. 26, 1918. Date of appl., Aug. 12, 1916.

THE apparatus consists of a vessel provided with a central inlet tube which passes through the bottom and projects upwards within the vessel. The inlet tube supports a number of superposed concavo-convex diaphragms, whilst in the upper portion of the vessel are retarding discs mounted on a rod projecting downwards from the top of the vessel. A cap carried by this rod is arranged above the discharge end of the inlet tube, whereby the liquid is directed upon the diaphragms. An outlet for the vapour is provided at the top of the vessel. The outlet tube for the liquid is at the bottom of the vessel and surrounds the inlet tube. —J. H. P.

Reaction tower. C. S. Robinson, Cambridge, Mass, Assignor to E. B. Badger and Sons Co., Boston, Mass. U.S. Pat. 1,257,400; Feb. 26, 1918. Date of appl., June 16, 1917.

A TOWER for effecting reaction between a liquid and a gas in the course of which heat is evolved and the specific gravity of the liquid is increased, comprises a series of reaction chambers, one above the other, and means for admitting liquid to the uppermost chamber and transferring it to the one below and for admitting gas to the bottom chamber and leading it up through the others. Means are provided for local cooling and circulation of the liquid. —J. H. P.

Pulverising-machine. C. A. Koehler, Easton, Pa., and C. C. Crosson, Alpha, N.J. U.S. Pat. 1,257,882, Feb. 26, 1918. Date of appl., Aug. 14, 1916.

A STATIONARY horizontal drum has a hollow shaft by means of which the grinding beaters are rotated. The drum is divided into two chambers by a vertical partition between the last set of beaters and the end wall, the portion of the partition above the shaft being perforated and forming a sieve. The portion of the hollow shaft between the screen and the end wall is provided with inlets opening into the drum. —W. H. C.

Distilling methods and apparatus. E. A. R. Chenard, Cognac, France. Eng. Pat. 5014, Mar. 31, 1915. Addition to Eng. Pat. 10,783 of 1913.

SEE Addition of Mar. 31, 1914, to Fr. Pat. 443,499 of 1912; this J., 1915, 480.

Evaporators. W. L. De Baufre, Annapolis, Md., U.S.A. Eng. Pat. 114,164, Oct. 24, 1916. (Appl. No. 15,136 of 1916.)

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Coals; Moisture content of some typical —. G. A. Hulett, E. Mack, and C. P. Smyth. Amer. J. Sci., 1918, 45, 174—184.

FOUR samples of American bituminous coals contained the following amounts of moisture:—New River, 1.50; Pittsburgh, 2.45; Indiana, 6.82; Wyoming, 8.20%. The samples were passed through a 60-mesh sieve and precautions were taken to avoid loss or gain of moisture after this operation. The method employed consisted in condensing the moisture evolved on heating the coal on a tube containing solid carbon dioxide and inserted in the top of the tube containing the coal, the air being exhausted from the apparatus. The results obtained were about 30% higher than those yielded by the standard method.—W. P. S.

Coke; Determination of moisture in —. A. C. Fieldner and W. A. Selvig. Tech. Paper 148, U.S. Bureau of Mines, 1917. [14 pages.]

IN the determination of moisture in coke, the temperature, time of drying, humidity of drying atmosphere, and fineness of sample may be varied considerably without appreciably affecting the result. Temperatures ranging from 105° to 200° C. produced a variation not exceeding 0.3%. The circulation of air dried by sulphuric acid through the drying oven, as specified for coal analysis, is unnecessary; also, no gain of weight takes place during prolonged drying owing to absorption of oxygen, as is usually the case with coal. A rapid and sufficiently accurate method ($\pm 0.5\%$), and one which may be used advantageously at the place of sampling, is to heat to constant weight a large sample of lump coke in any convenient oven, or on a stove, hot plate, or steam coil between 100° and 200° C.—L. A. C.

Gasoline; Testing natural gas for —. G. G. Oberfell. J. Ind. Eng. Chem., 1918, 10, 212—214.

FOR testing casing-head gas at the source of production a simple portable apparatus has been devised for working under atmospheric pressure. The absorption vessel has a capacity of about 1 cub. ft., and consists of a galvanised iron cylinder, 10 ins. in diameter and 2 ft. long, with conical ends with $\frac{1}{4}$ in. nipples and valves at each end. The vessel is calibrated with water. The absorber is attached to the gas supply in a vertical position by rubber tubing and gas is passed through it for 30 mins. Connection is made from the top when the gas is lighter than air and from the bottom when it is heavier. In either case the connection is made at the top for the last 15 mins., so as to expel any small amount of oil left from the previous test. All the air having been displaced, the valves are closed with the gas at atmospheric pressure; temperature and barometer reading are noted. The bottom nipple is then connected with a cylindrical glass oil-pipette, delivering about 850 c.c. of oil between two marks, the connecting tube having previously been filled with oil. The oil employed is "mineral seal oil" which has been ascertained to give no distillate at 350° F. (176.5° C.). The admission of oil to the absorber is started by applying pressure, after which the diminution in volume of the gas will draw in the remainder. If there is much diminution, air must be admitted to avoid collapse of the vessel. The oil is shaken in the absorber for 20 mins., then withdrawn and tested for gasoline content by distillation. The apparatus consists of a copper flask of 1000 c.c. capacity, having a tall metal vapour pipe with the bulb of a thermometer extending $2\frac{1}{2}$ ins. below the branch outlet. The condenser is a glass tube with three bulbs of about

80 c.c. total capacity, surrounded by an ice-water bath in an inverted 1-gallon can from which the bottom has been removed. The receiver is a cylinder graduated to read in $\frac{1}{10}$ c.c. 800 c.c. of oil is taken for distillation, which is carried on until the thermometer registers 350° F. (176.5° C.) The quantity of distillate may be less than 1 c.c. and its specific gravity is taken either in a graduated cylinder for samples between 4 and 10 c.c. or in a pycnometer made from small-bore tubing for samples less than 4 c.c. Results are calculated as yield of gasoline in gallons per 1000 cub. ft. of gas at standard temperature and pressure.

—J. F. B.

Fats and fatty acids from petroleum. R. J. Moore and G. Egloff. *Met. and Chem. Eng.*, 1918, 18, 308—311.

FOUR types of reaction have been proposed for the synthesis of fats and fatty acids from paraffin, olefine, and naphthene hydrocarbons:—(1) Conversion of saturated paraffins into halogen substitution products, the products being converted into alcohols which can be further oxidised to fatty acids. (2) The Grignard reaction has been applied to chlorinated paraffins containing up to ten carbon atoms and the corresponding fatty acids prepared. (3) The naphthenic oils from the Russian and Galician wells are known to contain oxygen compounds; octanaphthenic and adipic acids have been identified. On neutralisation such acids yield soaps. (4) Oxidation of paraffins and olefines forms the most direct process. Vaseline has been converted into a soap by oxidation with peroxides. Molten paraffin wax has been oxidised to fatty acids by prolonged treatment with a blast of air or oxygen. Olefines which are easily obtainable by pyrogenic treatment of paraffins are still more readily oxidised. The authors consider the commercial synthesis of fats as reasonably probable in the near future. The economic importance of this in view of the present depletion of the world's herds of livestock is indicated.—H. J. H.

Peat; Manufacture of fuel from—W. Goodwin and A. Macrae, Rhyl, Wales. Eng. Pat. 114,026, Mar. 15, 1917. (Appl. No. 3752 of 1917.)

PEAT is passed through a crushing mill, similar to that used for crushing sugar cane, to break up the fibre and expel a large proportion of the water, and the resulting thin cakes are passed between rollers maintained at a high temperature by superheated steam or electrical resistances. The peat is then allowed partly to dry in a storage chamber and is subsequently distilled at a low temperature in a series of retorts heated by electrical resistances embedded in the peat, the removal of the remaining moisture being facilitated by the maintenance of a vacuum in the retorts. The products are drawn through the usual condensers and washers to suitable receivers, and any permanent gas passes through the exhaustor to a gas holder. The residue is discharged through the bottom of each retort into a gas producer, where it is converted into carbon monoxide, which may be used for generating steam and also for driving the gas engines which operate the crushing and heating rolls and the dynamos for producing the electric current for the heating resistances. The perma-

nent gas may also be used in this manner. About 8—10% of peat tar is obtained which is converted into motor spirit and heavy oils by fractional distillation, and ammonium sulphate is obtained from the washers.—W. F. F.

Artificial fuel; Process for the manufacture of— from waste products. R. Brown, Southall. U.S. Pat. 1,256,494, Feb 12, 1918. Date of appl., Sept. 17, 1917.

ASH-BIN refuse normally containing coal, etc., is finely divided and pressed into blocks or briquettes without a binder other than the contained moisture. The blocks are then treated with a liquid binding material consisting of equal parts of oil tar and pitch in the proportion of 10% of the weight of the combustible portion of the waste material.—W. F. F.

Coke ovens and muffle and like furnaces; Gas fired — Simon-Carves, Ltd., and J. H. Brown, Manchester. Eng. Pat. 113,696, Mar. 24, 1917. (Appl. No. 4255 of 1917.)

In a battery of coke oven or muffle or like furnaces, the combustible gas or mixture of gases, with or without part of the necessary air, is fed to a series of horizontal passages, H, below every alternate

oven, A. The gas passes upwards through the vertical chambers, B, provided with baffles, N, to the horizontal passages, E, and thence to the combustion chambers on each side of the ovens, A. The remainder of the air passes through similar vertical chambers, b, below alternate ovens, a, to the same combustion chambers. These chambers are each divided into two parts by a transverse vertical partition extending nearly to the top, and the burnt gases pass down the other side of the partition and through passages, F, to the two vertical chambers, B¹, B², or b¹, b², provided with baffles, and enclosing the gas chamber, B, or air chamber, b, to preheat the gas or air supply. Rich coke-oven or other gas may also be admitted to the combustion chamber through the horizontal passages, O, and conduits, O¹.—W. F. F.

Gas plant; Method for preventing the choking up of—A. Riedel, Kössern, Saxony, Eng. Pat. 101,219, Aug. 16, 1916. (Appl. No. 11,574 of 1916.) Under Int. Conv., Aug. 16, 1915.

IN apparatus for the dry distillation of coal, magnesium chloride or calcium chloride is added to the charge in sufficient quantity to convert the whole of the nitrogen into ammonium chloride. The pipe connections between the retort and condenser are insulated and maintained above 450° C., and the condenser is maintained just below 450° C., to condense the ammonium chloride in a comparatively pure state.—W. F. F.

[Gas] retorts and methods of working the same. J. West, Southport, and W. Wild, Blackpool. Eng. Pat. 113,981, Dec. 9, 1916. (Appl. No. 17,714 of 1916.)

RETORTS for the destructive distillation of coal or other carbonaceous material are arranged horizontally or slightly inclined, and are flattened in cross-section. Each retort increases in size slightly from the inlet to the outlet, and the retorts are arranged one above the other in pairs, the pairs being spaced apart horizontally in a casing. Coal is fed into one end from a hopper, and pressed forward by a plunger reciprocating continuously so that the retort is kept fully or nearly fully charged. Each pair of retorts is surrounded at the inlet end by a combustion chamber, so that the coal is immediately subjected to a very high temperature and the outer layer of the charge is immediately coked. Progression of the charge along the retort is thereby facilitated. The hot combustion gases then circulate through a chamber surrounding the middle zone of the retort, and secondary air passes to the combustion chamber through a heating chamber surrounding the discharge end of each retort. Three distinct temperature zones are thus provided for each retort. Separate discharge passages for the coke and conduits for the gas are provided at the larger end of each retort.

—W. F. F.

Gas generators. T. R. Wollaston, Manchester. Eng. Pat. 113,856, Mar. 19, 1917. (Appl. No. 3962 of 1917.)

IN an apparatus for generating gas from coal or other carbonaceous material, in which the gas is afterwards treated for the extraction of by-products, a producer of ordinary construction is provided with narrow vertical retorts mounted on the top, through which the producer gas passes to a common central outlet. The coal is fed downwards through the retorts, each of which is provided with means for regulating the passage of the coal and the upward flow of gas and coal distillates. The controlling device may be a perforated helical strip mounted on a vertical spindle which is slowly rotated. In another form the controlling device may consist of a series of perforated cones mounted on a vertical spindle, which pass within inverted perforated cones fixed to the retort wall. The vertical spindle is reciprocated vertically to allow the passage of coal between the pairs of conical members.—W. F. F.

Gas washer-scrubbers. F. Thuman, London. From J. A. P. Crisfield, Philadelphia, Pa., U.S.A. Eng. Pat. 113,937, Nov. 14, 1917. (Appl. No. 16,744 of 1917.)

A CLOSED vertical cylindrical casing is provided with an inner concentric cylindrical partition depending from the cover and dipping into the liquid which approximately half fills the casing. The gas to be washed is introduced by a central pipe dipping into the liquid and passes into the

outer vessel through an opening in the side. A spray of liquid is also directed outwards through this opening, and the gas and spray impinge on a series of angle bars projecting from the wall of the outer casing. The washed gas then passes round the annular space surrounding the cylindrical partition to an outlet at the opposite side. Projecting baffles are provided on both walls of this annular space to intercept the gas current. The liquid is maintained at the desired level in the casing by an overflow pipe arranged in a small chamber attached to the side of the main casing.

—W. F. F.

Fullers' earth [from mineral oil refining] and similar materials; Process for treating—C. M. Husted, Jersey City, N.J., Assignor to Standard Oil Co. U.S. Pat. 1,256,233, Feb. 12, 1918. Date of appl., June 25, 1915.

FULLERS' earth, which has been used for treating hydrocarbons, is supplied continuously together with acid to a chamber, where it is agitated by tumbling. The mixture is continuously removed from the chamber, and impurities and reaction products are separated by washing and settling. The earth is again washed by agitation, and then dried. Any earth contained in the impurities and reaction products is separated, washed, and dried.

—W. F. F.

Wax-bearing oil; Apparatus for cooling—for pressing. E. P. Folger, Brooklyn, N.Y., Assignor to Standard Oil Co., Bayonne, N.J. U.S. Pat. 1,256,460, Feb. 12, 1918. Date of appl., Jan. 13, 1914.

A VERTICAL cooling chamber of annular horizontal cross-section is provided both inside and outside with chambers for a cooling liquid, and suitable inlet and outlet openings are provided for the passage of the oil and cooling liquid in opposite directions. A head is attached to the top of the central cooling cylinder, the outlet of which forms a conduit extending vertically upwards above the head and is supported on it by a ball bearing. The outer surface of the conduit forms a bearing for a rotating sleeve, having a portion projecting horizontally over the annular cooling chamber and carrying a scraping device. The scraper comprises an annular frame composed of a number of rings, one of which rests on a ball bearing on the bottom of the chamber, the intermediate rings being connected by vertical strips. The scraper bars are mounted in the frame and acted upon by springs in such a way that they are pressed simultaneously against the outer and inner walls of the cooling chamber and thus remove deposited material.—W. F. F.

Petroleum; Method and apparatus for treating—R. C. Dundas, Los Angeles, Cal. U.S. Pat. 1,257,199, Feb. 19, 1918. Date of appl., Aug. 11, 1917.

EACH of a series of chambers contains a vaporising flue suspended free of the wall and connected at the top with the next chamber, the last chamber of the series being connected with a condenser. Heated gas is passed through a pipe connected with the condenser into the first chamber of the series and passes through the chambers in succession, first downwards round the outside of the vaporising flue and then upwards within the flue; the oil to be treated is sprayed into the bottom of each vaporising flue. Within each chamber is a means for collecting condensed products.—L. A. C.

Aromatic bodies from petroleum oils; Process for the production of—F. W. Mann, Berkeley, and M. L. Chappell, El Segundo, Cal., Assignors to Standard Oil Co., Richmond, Cal. U.S. Pat. 1,257,906, Feb. 26, 1918. Date of appl., Nov. 12, 1917.

PETROLEUM oils containing oils of the carbocyclic

series are dehydrogenated by treatment with a volume of air ranging from 500 to 800 cub. ft. for each 15 to 20 galls. of oil, in the presence of nickelous oxide, at a pressure of from 1 to 4 ins. of mercury below atmos. pressure and between 600° and 750° C., the air being mixed with the products of combustion required to maintain this temperature.—L. A. C.

Sulphur; Eliminating—from oils. E. V. Evans, London. U.S. Pat. 1,257,829, Feb. 26, 1918. Date of appl., Oct. 25, 1915.

SEE Eng. Pat. 22,147 of 1914; this J., 1915, 1240.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

PATENTS.

Gas-burning apparatus [for heating and lighting]. C. Ellis, Montclair, N.J., Assignor to Surface Combustion, Inc., Wilmington, Del. U.S. Pat. 1,256,301, Feb. 12, 1918. Date of appl., May 8, 1912. Renewed June 28, 1917.

IN a heating and lighting apparatus of the surface combustion type, a thick porous diaphragm mounted in a casing is formed of porous granules of substantially uniform size, the surface granules being coated with rare earth actinic material to promote luminosity. A gas chamber extends over one side of the diaphragm and an air chamber extends similarly over one end. A number of cooling passages are provided in the diaphragm, through which air passes to the air chamber, and the air is conveyed into the gas chamber and mixed with gas by means of a gas jet passing through an injector tube which connects the two chambers. The combustible mixture then passes through the porous diaphragm where it is burnt. A regulating damper is provided to control the amount of air drawn through the cooling passages by the injecting nozzle.—W. F. F.

Incandescence lamps; Electric—L. Hamburger, D. Lely, jun., and Naaml. Vennoots. Philips' Gloeilampenfabrieken, Philipsdorp, Netherlands. Eng. Pat. 113,626, Nov. 29, 1916. (Appl. No. 17,161 of 1916.)

THE inner surface of the bulb is provided with a thin layer of calcium fluoride, which during the burning of the lamp does not evolve a gas giving an active or measurable vapour pressure, but prevents the obscuring of the bulb.—B. N.

Carbonaceous material; Separation of volatile products from solid—W. W. White, London. U.S. Pat. 1,257,772, Feb. 26, 1918. Date of appl., Sept. 1, 1916.

SEE Eng. Pat. 14,800 of 1915; this J., 1917, 286.

SEE Fr. Pat. 469,212 of 1914; this J., 1915, 36.

III.—TAR AND TAR PRODUCTS.

Ammonia recovery at tar-distilling plants. C. R. Woodward. Met and Chem. Eng., 1918, 18, 299—301.

IT is not customary at tar distillation plants in America to recover the ammonia from the liquor settling out of the tar or from the aqueous portion of the distillate. Analyses of the liquors settling from gas works and coke oven tars showed up to 1.5% NH₃ and in the distilled liquor up to 2.52% and 3.12% if caustic soda was present during distillation. The ammonia in the distilled liquor was free and thus required no lime for recovery. These liquors form a fruitful and at the present time profitable source of ammonia.—H. J. H.

Monomethylaniline and dimethylaniline; New method of preparation of—by catalysis. A. Mailhe and F. de Godon. Comptes rend., 1918, 166, 467—469.

IF a mixture of the vapours of aniline and a slight excess of methyl alcohol is passed over aluminium oxide at 400°—430° C., a mixture of methyl- and dimethylaniline, containing only traces of aniline, is obtained. Methylaniline may be similarly converted into dimethylaniline. During the process the alumina in time becomes yellow and then brown, and loses some of its activity. This may be restored by a simple calcination. For this process it is not necessary that the aniline should be free from water or the methyl alcohol from acetone. (See also J. Chem. Soc., May, 1918.) —W. G.

Methyltoluidines; Preparation of the—by catalysis. A. Mailhe and F. de Godon. Comptes rend., 1918, 166, 564—566.

THE method used for the methylation of aniline (see preceding abstract) is equally applicable to the three toluidines. The first passage of the mixed vapours of the toluidine and methyl alcohol over alumina at 350°—400° C. gives a mixture of methyl- and dimethyltoluidine, which is entirely converted into dimethyltoluidine by a second passage over the alumina with methyl alcohol. (See also J. Chem. Soc., May, 1918.)—W. G.

Isomers; Limits of accuracy of Holleman's method of determining the composition of a mixture of two or three—[Application to the nitranilines.] J. B. Nichols. J. Amer. Chem. Soc. 1918, 40, 400—403.

THE method (Holleman, "Die direkte Einföhr. von Substituenten in den Benzolkern," 1910) was applied to mixtures of the three nitranilines containing a relatively small proportion of the ortho-compound. The temperature at which the mixture begins to crystallise and the eutectic temperature were measured. The difference between the observed eutectic temperature and the eutectic temperature for mixture of *m*- and *p*-nitraniline is proportional to the amount of *o*-nitraniline present. Since the temperature at which *p*-nitraniline crystallises out is not appreciably altered when a small proportion of the admixed *m*-compound is replaced by the same amount of the *o*-compound, it is apparent that the two temperature readings will permit of an estimation of the proportions of the three isomers in a mixture. In the case of

the nitranilines, the method appears to give satisfactory results if the percentage of the third isomer (*o*-nitraniline) does not exceed about 10%. (See also J. Chem. Soc., May, 1918.)—H. M. D.

PATENTS.

Cresols; Process for the separation of—G. A. Darzens, Paris. Eng. Pat. 107,961, Dec. 4, 1916. (Appl. No. 17,398 of 1916.) Under Int. Conv., July 11, 1916.

THE capacity of *p*-cresol and *m*-cresol to form addition products with oxalic acid and with anhydrous sodium acetate respectively is utilised to effect a separation of the three isomers. It is necessary during the formation of these products to exclude moisture and to use solvents having a chemical nature different from that of the cresols, e.g., ligroin, benzene, toluene, the xylenes, chloroform, chlorobenzene, or like chlorohydrocarbons. The addition products separate as solids, and are filtered off; they are readily decomposed by water. It is advantageous to separate the *o*-cresol first by fractional distillation *in vacuo*, the compound being obtained sufficiently pure to crystallise on cooling, and by draining the crystals, very pure technical *o*-cresol may be produced. *Example*: 100 parts of the residue obtained after distilling off the *o*-cresol is mixed with 100—150 parts of ligroin and 15—17 parts of anhydrous oxalic acid in a mixer provided with a cover and an agitator. After sufficient time, the solid compound is separated, washed with ligroin, and treated with a suitable quantity of water in a lead-lined still provided with a steam heating and distilling apparatus. The *p*-cresol distils off, leaving a solution of oxalic acid, which is readily recovered. The liquid left behind in the separation of the solid compound may be treated in a similar manner with sodium acetate to recover the *m*-cresol.—L. A. C.

Phenols; Process of producing—Bostaph Engineering Co., Assignees of A. S. Ramage, Detroit, Mich., U.S.A. Eng. Pat. 106,274, Mar. 27, 1917. (Appl. No. 4136 of 1917.) Under Int. Conv., Apr. 20, 1916.

Process of effecting organic chemical reactions. Eng. Pat. 110,517. See I.

Process for the production of aromatic bodies from petroleum oils. U.S. Pat. 1,257,906. See IIa.

IV.—COLOURING MATTERS AND DYES.

Camwood, barwood, and sanderswood; Colouring matters of—[and of St. John's wort]. P. O'Neill and A. G. Perkin. Chem. Soc. Trans., 1918, 113, 125—140.

THE more insoluble colouring matter of camwood ("iso-santalin") is most simply expressed as $C_{22}H_{18}O_5(OCH_3)_2$; it is isomeric with the santalin of sanderswood, for which the same formula is therefore proposed in place of $C_{15}H_{11}O_4(OCH_3)_2$ suggested by Cain and Simonsen (this J., 1912, 580). Santalin and iso-santalin are respectively accompanied in the dyewood by the more readily soluble deoxysantalin and deoxyisotantalin, which probably have the formula $C_{22}H_{16}O_5(OCH_3)_2$ or $C_{22}H_{16}O_5(OCH_3)_2$. Santalin from sanderswood appears to be identical with the colouring matter obtained in a similar way from barwood. Barwood also contains santal. $C_{15}H_{11}O_4(OCH_3)_2$, and santalone, $C_{22}H_{16}O_5(OCH_3)_2$, the latter being

identical with the substance, $C_{14}H_{12}O_4$ described by Weidel (Z. für Chem., 1870, 6, 83). The colouring matter of St. John's wort is quercetin, and no gossypetin is present.—F. W. A.

PATENTS.

Azo dyestuffs; Manufacture of red—British Dyes, Ltd., J. Turner, and H. Dean, Huddersfield. Eng. Pat. 113,825, Mar. 6, 1917. (Appl. No. 3287 of 1917.)

THE diazo compound from *p*-chloro-*o*-anisidine ($OCH_3 : NH_2 : Cl = 1 : 2 : 4$) is combined with 1'-, 1'-5-, or 2'-6-naphtholsulphonic acid, giving a product which dyes wool a bright red, showing excellent fastness to milling or fulling.—L. A. C.

Hydrazone dyestuffs; Manufacture of new metal compounds of—, and process of dyeing with such compounds. O. Imray, London. From Soc. of Chem. Ind. in Basle, Switzerland. Eng. Pat. 114,189, Mar. 20, 1917. (Appl. No. 4057 of 1917.)

HYDRAZONE dyestuffs produced by condensing a hydroxyarylhydrazine or an arylhydrazinecarboxylic acid or a hydroxyarylhydrazinecarboxylic acid, or a substitution product of one of these, with an aldehyde of the benzene, naphthalene, or furfural series, or a ketone or diketone of the aromatic series, or a substitution product of one of these, are converted into new metal compounds, soluble in water, by treating an aqueous solution or suspension of the dyestuff with a metal or metal compound, e.g., copper, or a copper salt, or a salt of chromium, nickel, cobalt, iron, or the like. Similar compounds from other dyestuffs are described in Eng. Pats. 1611, 12,249, 15,456, 16,803, and 16,916, of 1915 (this J., 1916, 301, 922, 1255, and 1917, 78). The new compounds dye animal fibres in an acid bath vivid tints which are fast to light and washing without any after-treatment. Those compounds which contain both a hydroxyl and carboxyl group can be used for dyeing as described in Eng. Pat. 13,204 of 1915 (this J., 1916, 419). Where the metal or metal salt does not decompose the hydrazine compound, the metal compound may be prepared by condensation in the presence of the metal or metal salt, as described for the preparation of copper compounds of *o*-hydroxyazo dyestuffs in Eng. Pat. 15,127 of 1915 (this J., 1916, 1101). *Example*: 18 parts of the sodium salt of the dyestuff from 1-hydroxy-2-phenylhydrazine-4-sulphonic acid and resorcinyl aldehyde are dissolved in 300 parts of water at 30° C. and the solution mixed with a solution of 13 parts of crystallised copper sulphate in 20 parts of water. On adding common salt, the copper compound separates as a green-yellow precipitate, which dyes wool yellow-green in an acid bath.—L. A. C.

Dyes of the acridine series; Halogenated—H. Grünhagen, Berlin-Karlshorst, Assignor to Act.-Ges. für Anilin-Fabrikation, Berlin, Germany. U.S. Pat. 1,255,739, Feb. 5, 1918. Date of appl., July 29, 1916.

A new dyestuff of the acridine series which forms a brown-black powder dyeing leather reddish-yellow, is obtained by heating formyl-chloro-*m*-phenylenediamine ($NH_2 : NH \cdot CHO : Cl = 1 : 3 : 6$) with *m*-aminodimethylaniline hydrochloride. The claims cover other dyestuffs of this series of the general formula

in which R_1 and R_2 signify univalent substituents, including hydrogen, and in which one or more hydrogen atoms in the benzene nuclei are replaced by halogens.—L. A. C.

fugitive, and for quantitative purposes it is better to suspend the treated end of the strand over the ammonia for a few minutes. The colour does not develop so rapidly, but is more permanent, and the various coloured fibres can be picked out by the help of a reading glass. The correctness of the sorting can then be confirmed quickly by a qualitative test of the other ends of the fibres.

—J. F. B.

Paper; Blue and brown print—: characteristics, tests, and specifications. F. P. Veitch, C. F. Sammet, and E. O. Reed. J. Ind. Eng. Chem., 1918, 10, 222—226.

THE best grades of engineering blue and brown print papers are bond papers of high quality, preferably made entirely from rag fibre, so sized as to be resistant in a proper degree to the absorption of the sensitising solution and yet to take the coating uniformly. The paper is subjected to much handling both in the wet and dry condition. The durability against wear is best measured by the folding test, but the resistance to tearing in the washing treatment depends more on the tensile strength of the paper in the wet condition. This is very important when sheets of paper 10 ft. or more in length have to be handled. For papers not intended as permanent records, up to 50% of a mixture of straw or sulphite pulp may be used with the rag stock. The determination of folding endurance need only be made in the weaker direction (usually transverse) and a high resistance can only be obtained by the use of a high grade rag stock. This must be so beaten and sized as to produce a flexible sheet with a well-closed texture. Wet strength depends not only on the character of the stock and the beating, but also on the effectiveness of the sizing and the formation of the sheet. For proper coating, the surface sizing and glazing should not be too high. The mechanical properties of coated and developed blue print paper should not be inferior to those of the original paper, but brown print paper suffers great deterioration after coating, owing to the action of the sensitising chemicals, the bursting strength and, particularly, the folding resistance being very much lower. Three grades of blue print paper cover all types of requirements, but for brown printing only the highest grade is permissible. The tensile strength in the wet condition is determined on strips 15 mm. wide and 10 cm. long after immersion in water at 70° F. (21° C.) for 20 mins. Sulphite pulp mixed with the rag gives paper with low folding resistance and lacking durability. Straw mixed with rag usually gives a good wet strength and fair folding test, but the paper lacks durability. Animal sizing is favourable to the folding endurance, while excess of rosin is unfavourable. For satisfactory coating and durability the paper should not contain more than 3% of either animal or rosin size. The wet strength and the folding resistance do not necessarily run parallel. The following are the principal points in the standard specifications for uncoated and coated blue print papers and for uncoated brown print papers of medium substance (17×22 ins., 500's—24 lb.):—

Grade.	Rag stock.	Bursting test.	Wet strength.		Folding test.
			Longitudinal.	Transverse.	
	%	points.	grms.	grms.	Weak direction.
Blue 1st	100	50	800	500	800
" 2nd	100	45	800	500	500
" 3rd	50	38	800	500	150
Brown 1st	Same as Blue 1st				
" 2nd			800	500	400

[*Fabrics; Coating* [—] *with liquid materials.* W. B. Makins, London, Eng. Pat. 113,844, Mar. 9, 1917. (Appl. No. 3508 of 1917.)

A MECHANICAL arrangement for coating surfaces with liquid materials, particularly applicable to the "doping" of aeroplane wings, consists of a system of travelling spraying devices, arranged in a closed chamber, so as to deliver slightly overlapping bands of liquid coating material as the sprays travel over the object to be coated. The valves of the spraying devices are controlled for opening or closing, by a rod common to all, by a multiple linking, the links bearing studs for levering up the valves, and the rod being operated by tappets so as to open or close the valves at or near the ends of the stroke of the reciprocating carriage. It is important that all the sprays should act at an equal distance from the coated surface and means are provided to accommodate the adjustment for curved or irregular surfaces.—J. F. B.

Fabric; Colloid-treated —. S. P. Lovell, Brockton, Mass. U.S. Pat. 1,256,240, Feb. 12, 1918. Date of appl., June 27, 1917.

A SHEET of fibrous fabric is impregnated with a dissolved or diffused colloidal material which is insoluble in water, and the fabric is immediately passed to a water bath in which it is immersed until the solvent is displaced and the colloid precipitated. The interstices of the fabric are thus filled with powdered colloid material, insoluble in water.—J. F. B.

Cloths; Method and apparatus for removing oils, fats, and greases from— G. W. Nagel, Assignor to W. L. Newman, jun., and C. F. Bliss, Chicago, Ill. U.S. Pat. 1,256,356, Feb. 12, 1918. Date of appl., Feb. 8, 1917.

THE cloths are subjected to centrifugal action in a perforated drum, surrounded by a casing provided with a discharge outlet. A perforated coil is fitted in the space between the casing and the drum, from which jets of steam are directed against the outer wall of the drum.—W. P. S.

Drying-machine [for fabrics]. J. S. Johnston, Utica, N.Y. U.S. Pat. 1,256,570, Feb. 19, 1918. Date of appl., Mar. 21, 1913.

THE fabric to be dried is drawn over the surface of a hot air pipe by a stretching and folding frame.—W. H. C.

Straw; Process of treating—in the preparation of textile fibres. V. Volpato, Milan, Italy. Eng. Pat. 113,853, Mar. 16, 1917. (Appl. No. 3873 of 1917.)

STRAW, particularly rice straw, is digested under pressure with a solution containing sodium carbonate and lime, preferably in the proportions of 2·5 kilos. of calcium oxide, 5 of sodium carbonate, and 100 of water. It is then immersed for about 50—60 minutes in an alkaline bath of suitable concentration (15°—16° B.; sp. gr. 1·109—1·118) and is subsequently washed in a bath of ammonium fluoride at 1°—2° B. (sp. gr. 1·007—1·013) and

finally in water containing a small quantity of sodium carbonate to neutralise any remaining acidity.—J. F. B.

Cotton stalks; Process of treating—L. D. Jones, Assignor to H. D. Deacon and Z. E. Marvin, Dallas, Tex. U.S. Pat. 1,257,080, Feb. 19, 1918. Date of appl., May 10, 1917.

COTTON stalks are disintegrated in the presence of steam, the disintegrated stalks are subjected to the action of a hot solution of caustic alkali and soap, and the treated mass is dried.—J. F. B.

Drying apparatus [for paper]. P. Mueller, Berlin. U.S. Pat. 1,255,915, Feb. 12, 1918. Date of appl., July 30, 1915.

A DRYING apparatus for wet sheets of paper or other material comprises two oppositely inclined flat surfaces meeting at their upper edges in a rounded joint. A heat-radiating device is provided between the surfaces.—W. F. F.

[Paper making] machine; Fourdrinier—C. E. Pope, Holyoke, Mass., Assignor to Great Northern Paper Co., Millinocket, Me. U.S. Pat. 1,257,737, Feb. 26, 1918. Date of appl., Apr. 27, 1915.

IN a Fourdrinier paper machine the wire after passing the couch press is carried forward round another roll situated between the couch press and the wet felt roll. The extra roll, which guides the wire back, is positively driven, e.g., from the couch roll drive, so as to maintain the wire between it and the couch press taut and at a predetermined inclination. Beneath the wire at this place a blower is arranged, so as to blow the paper off the wire after leaving the couch press and before reaching the end-roll and deliver it to the wet-press felts.—J. F. B.

Wood-pulp; Process of producing chemical—J. O. Lundberg, Flatby, Norway. U.S. Pat. 1,257,290, Feb. 19, 1918. Date of appl., Nov. 9, 1914.

SEE Ger. Pat. 284,628 of 1914; this J., 1915, 1048.

Waterproof material for use in constructional purposes, as a substitute for leather, for street paving and the like. Eng. Pat. 111,485. See IX.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Wool; Absorption of sulphuric acid by—, with some notes on the theory of dyeing. W. Harrison. J. Soc. Dyers and Col., 1918, 34, 57–58.

WOOL, after boiling with dilute sulphuric acid acquires a positive electrical charge which changes over to negative when boiling water is passed through the wool, showing that the acid has been removed. This conclusion was apparently not confirmed by Fort and Lloyd (this J., 1914, 133), who found that some of the acid was permanently retained against washing with boiling water. In the present experiments, 5 grms. of wool was boiled for one hour, with 300 c.c. of water containing 4.90% of sulphuric acid on the weight of the wool. The wool was rinsed well in cold water and then packed tightly in a glass tube. The unabsorbed acid was titrated and the wool extracted with boiling water, 300 c.c. of water being pumped through the tube for each test. Twenty-four extractions were made, the liquid from each of them being titrated separately. The wool contained 3.08% of acid when packed in the tube, about 1% after the fourth extraction, and was free from acid after the twenty-third. No measurable amount of acid was retained and the treated wool had no greater affinity for acid dyestuffs than untreated wool.

The above observations have a bearing on the dyeing of wool with acid colours. Wool previously treated with acid and washed in the ordinary way is bound to give up acid when boiled with water containing acid dyestuffs. The qualitative experiments of Fort (this J., 1913, 907) are thus accounted for. It is in accordance with the known facts that there should be conditions of concentration and temperature where the amount of sulphuric acid passing into the solution should bear a molecular relationship with the amount of dyestuff or other salt absorbed. Similar relationships have been noted between starch and barium hydroxide and between starch and iodine, but when the concentrations are altered the molecular relationship does not hold. It would therefore appear that the dyeing of wool with acid dyestuffs is a colloid-chemical problem and not an ordinary chemical reaction.—J. F. B.

Dyeing; Theory of—H. R. Krut and J. E. M. van der Made, Proc. K. Akad. Wetensch., Amsterdam, 1918, 20, 636–641.

IN the distribution of basic dyes between isobutyl alcohol and water the effect produced by the presence of the sodium salts of different acids affords a series in which the anions are arranged in the same order as in the lyotropic series. Results obtained with Crystal Violet, Magenta, and Methylene Blue show the anions in the order— $\text{SO}_4^{''}$, $\text{PO}_4^{''}$, $\text{Cl}^{'}$, $\text{Br}^{'}$, $\text{NO}_3^{'}$, $\text{I}^{'}$, $\text{CNS}^{'}$. With acid dyessuch as Naphthol Yellow S and Alkali Blue, the anion influence is scarcely appreciable. Other experiments in which the influence of salts on the absorption of dyes by blood charcoal was examined show that the lyotropic influence is predominant in certain cases, whilst in others this is more or less masked by the influence of the electrical charges carried by the ions. Auramine O belongs to the former group and Methylene Blue B extra and Crystal Violet to the latter. The facts are discussed in reference to the various theories which have been put forward to explain the adsorption of dyes and the need for further experiments is emphasised. (See also J. Chem. Soc., May, 1918.)

H. M. D.

Laundry [textile] goods; Oxygen tendering of—P. Heermann, Chem.-Zeit., 1918, 42, 85–86.

THE use of perborate soaps and similar peroxide bleaching agents in laundries has been proved to produce, after several treatments, a very serious tendering which is more pronounced in linen fabrics than in cotton. On the other hand laundry treatments with caustic soda, soap and sodium silicate, or soap with scrubbing are comparatively mild in their effects. The destructive action of peroxide agents is greatly stimulated by the catalytic influence of certain metallic salts. Copper is extremely active and iron in a less degree (see also Briggs, this J., 1916, 80), and cloth spotted with solutions of salts of these metals is quickly tendered by perborate solutions; hypochlorite solutions act in a similar manner. The tendering of laundry goods may be attributed to the catalytic action of traces of metallic compounds in the "dirt" with which they are contaminated, and the use of all kinds of oxygenated washing agents is strongly to be condemned.

—J. F. B.

PATENTS.

Car-seats [dyed materials]; Process of treating [renovating]—J. M. Wilson, Montclair, N.J., Assignor to F. Murphy, Newark, N.J. U.S. Pat. 1,256,189, Feb. 12, 1918. Date of appl., Dec. 20, 1913. Renewed June 15, 1916.

DYED materials having a nap are cleansed and renovated by first carding the material to loosen the fibres of the nap by abrasion so that micro-

scopic filaments will extend therefrom, then treating with a solution which will cleanse the nap and release a portion of the excess dye at the base of the nap, e.g., a solution containing sodium oleate and alcohol, then bending the nap by pressure applied alternately in contrary directions to bring the free ends of each portion of the nap in contact with the released dye at the base of adjacent portions, then subjecting the material to the action of trisodium phosphate to cause the re-absorbed dye to reset, lastly removing any excess of the solution from the material, and drying.—J. F. B.

Dyeing elongated bodies of yarn or the like; Process of —. H. Krantz, Aachen, Prussia, U.S. Pat. 1,257,886, Feb. 26, 1918. Date of appl., Apr. 8, 1914.

Manufacture of new metal compounds of hydrazone dyesuffs and process of dyeing with such compounds. Eng. Pat. 114,189. See IV.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Alunite deposits of Australia and their utilisation. Advisory Council of Science and Industry. Bull. 3. pp. 38 and 9 plates.

DEPOSITS of alunite are worked at Carrickalinga, S.A. (K_2O content 10%), Warnertown, S.A. (K_2O content 7–9%), and Bullahdelah, N.S.W. (K_2O content 5.7–9.5%). The ore was, until recently, shipped to Runcorn for the manufacture of alum, but this has been suspended, and in view of the shortage of potash the Commonwealth Government has examined the possibilities of meeting it by suitable treatment of alunite. Experiments were made to increase the solubility of the potash by a simple roasting process. In laboratory trials it was found that at 500° C. the alunite was dehydrated giving a mixture of potassium aluminium sulphate and alumina. Decomposition to potassium sulphate and alumina occurred at higher temperatures and at 700° C. this was complete in 1 hour. At this temperature 77.7% of the SO_3 evolved was dissociated into SO_2 and O_2 . The calcined residue was leached with water and filter-pressed. On crystallisation a high grade salt containing more than 90% K_2SO_4 was obtained. The insoluble residue was an impure alumina, that from Carrickalinga ore containing 92% Al_2O_3 and that from Bullahdelah as low as 64% Al_2O_3 . Even the latter is purer than natural bauxite so that the residue may possibly be suitable for the manufacture of aluminium. Trials with a simple hand-rabbed reverberatory furnace showed that the process worked satisfactorily at temperatures from 750° to 1000° C., but above that loss of potash occurred through the formation of potassium aluminate. The decomposition was accelerated by incorporating with the ore carbonaceous matter, especially molasses, which facilitates the escape of the gases. Alunite has also been successfully used as a fertiliser in South Australia by admixture with limestone before burning. Roasted alunite also is suggested as suitable for use as a fertiliser in the vicinity of the deposits and where conditions of transport allow, American experiments having shown its superiority over potassium sulphate (Skinner and Jackson, this J., 1913, 618).—H. J. II.

Lime; Valuation of — for various purposes. R. K. Meade. J. Ind. Eng. Chem., 1915, 10, 214–219.

QUICKLIMES are classified as high calcium, calcium,

magnesian, and high magnesian. Magnesian limes contain 10–25% MgO and high magnesian limes 25% as a minimum. The sum of calcium and magnesium oxides must be at least 90% for selected and 85% for unselected. Carbon dioxide should not exceed 3% and 5% respectively; silica, iron oxide, and alumina, 5% and 7.5%. For constructional purposes the value of a lime depends on its physical properties although these are influenced by chemical composition; the important properties are sand-carrying capacity, crushing strength, and tensile strength. For plastering, good colour and plasticity are required; magnesian limes are generally preferred. For the chemical industries the value depends on the percentage of calcium oxide; for many purposes the presence of magnesia is not objectionable, but for the sugar and caustic soda industries it is considered harmful. Lump lime should be sampled in large quantities (100 lb.) and divided by quartering after crushing to 1 in. size; a 15-lb. sample should be sent for analysis in an air-tight container. For the slaking test 5 lb. is carefully wetted and allowed to slake for 24 hours, then washed through a 20-mesh sieve without rubbing; the residue must not exceed 3% for selected and 5% for unselected. To test the constancy of volume, equal parts of hydrated lime and Portland cement are mixed with water to a workable paste and a pat is made about 3 ins. in diam. and $\frac{1}{2}$ in. thick at the centre, tapering to a thin edge. This pat, when hardened on a glass plate for 24 hours in moist air and then exposed to steam above boiling water in a loosely closed vessel for 5 hours, should not show any deformation or cracking. The other methods employed are the same as those in use for testing cements. For chemical purposes the percentage of free lime is the most important factor. Several methods are in use, one of the oldest being to boil the ground sample with water and titrate quickly with hydrochloric acid in presence of phenolphthalein. The Scaife method is a modification of this in which the lime is boiled with water, cooled, and treated with less than the required quantity of acid; the residual lumps are broken up, the whole is transferred to a gauged flask and allowed to settle; titration is then completed with an aliquot portion of the clear liquid. Lunge's method of titrating with oxalic acid is well known, the sample being hydrated and prepared as a milk. The sucrose method has the advantage of giving a clear solution for titration; the sucrose solution must contain between 35 and 45% of sugar. The Solvay method requires a special flask in which the lime is caused to react with ammonium chloride and the clear liquid is withdrawn for titration in presence of methyl orange. A method is sometimes used in caustic soda works depending on the causticising of a solution of sodium carbonate.—J. F. B.

Chromates and bichromates; Determination of —. L. W. Winkler. Z. angew. Chem., 1918, 31, 46–48.

CHROMATES, or bichromates after they have been converted into chromate by boiling with calcium carbonate, and filtering, may be determined as barium chromate or silver chromate, the former being used in the presence of chlorides and the latter if the solution contains sulphate. As *barium chromate*, 100 c.c. of the solution containing about 0.2 gm. of alkali chromate is acidified with 1 c.c. of N/10 acetic acid, 1 gm. of sodium chloride is added (this makes the barium chromate granular and easy to filter), the solution is boiled, and treated, drop by drop, with 5 c.c. of 10% barium chloride solution. After 18 hours, the precipitate is collected, washed with 50 c.c. of cold water, dried for 3 hours at 132° C., and

weighed. If the precipitate is ignited before weighing it loses 0.25% in weight. The results obtained are accurate when dealing with a precipitate weighing about 0.3 grm., but with one-tenth of this quantity the weight found is about 1 mgrm. too low. Ammonium, potassium, calcium, and magnesium chlorides do not interfere, but nitrates, chlorates, and acetates increase the weight of the barium chromate precipitate. *As silver chromate.* 100 c.c. of the neutral alkali chromate solution is heated to boiling and treated with 5 c.c. of 10% silver nitrate solution. The precipitate is collected after 18 hours, washed with 50 c.c. of water saturated with silver chromate, dried for some hours at 132° C., and weighed. The precipitate should not be exposed to daylight. The presence of nitrates, chlorates, and acetates does not interfere, but sulphates cause the results to be too high, since some silver sulphate is precipitated with the silver chromate and cannot be removed by washing. The quantity of silver sulphate thus precipitated varies with the concentration of chromate and sulphate, and a table is given showing the corrections to be applied. (See also J. Chem. Soc., May, 1918.)—W. P. S.

Spent oxide [from gas works]; Analysis of —. Z. angew. Chem., 1918, 31, 45–46.

THE following procedure is recommended for the examination of spent oxide and other materials which have been used for the purification of gas. The substance is ground in a coffee mill and the moisture is determined by heating 25 grms. at 80° C. for about 4 hours or until the loss in weight between two successive weighings does not exceed 0.05 grm. To determine sulphur 10 grms. of the finely ground dried material is shaken with 75 c.c. of carbon bisulphide for some hours, a further 25 c.c. of carbon bisulphide is then added, the mixture is shaken, allowed to settle, and 50 c.c. of the clear solution is drawn off, and filtered. The filter is washed with carbon bisulphide, the filtrate and washings are evaporated in a weighed flask, the residue in the flask is dried at 100° C., and weighed. The quantity of sulphur found is calculated as a percentage of the original, moist material. Ferrocyanides are determined by shaking 10 grms. of the finely ground dry substance with 50 c.c. of 10% potassium hydroxide solution for about 12 hours, diluting the mixture to 255 c.c., and filtering; 100 c.c. of the filtrate is then added to 25 c.c. of hot ferric chloride solution (ferric chloride, 60 grms., concentrated hydrochloric acid, 200 c.c., and water to 1000 c.c.), the mixture is kept at 80° C. for some time, filtered, the precipitate washed with hot water, and the filter and precipitate then transferred to a beaker where they are stirred with 20 c.c. of 10% potassium hydroxide solution and a quantity of water until all blue colour has disappeared. The mixture is now washed into a 250 c.c. flask, diluted to the mark, shaken after the addition of 1 grm. of lead carbonate, and filtered; 100 c.c. of the filtrate is acidified with 5 c.c. of sulphuric acid (1:5), and titrated with copper sulphate solution (12 grms. per litre) which has been standardised against pure potassium ferrocyanide. Ferric chloride solution is used as an external indicator in the titration. Exactly the same quantities of reagents must be used in the standardisation of the copper sulphate solution as in titrating the test solution, and the conditions of the titration must be the same in each case.—W. P. S.

Iron trisulphide. W. Mecklenburg and V. Rodt. Z. anorg. Chem., 1918, 102, 130–148.

A KNOWLEDGE of the properties and conditions of existence of ferric sulphide is important in connection with the use of ferric oxide for purifying coal gas. Its formation by the prolonged

action of hydrogen sulphide on an aqueous suspension of freshly prepared ferric hydroxide in absence of air is described (see this J., 1917, 82). The trisulphide can be dehydrated without decomposition *in vacuo*, but when dry is pyrophoric if brought suddenly into contact with air. If spontaneous ignition is prevented, however, it is quite stable in air. By the action of excess of sodium sulphide solution on a solution of a ferric salt, or of excess of sodium polysulphide solution on one of a ferrous salt, a precipitate is formed having the composition $\text{Fe}_2\text{S}_3\cdot\text{Na}_2\text{S}$. The alkali sulphoferrites form dilute, deep green colloidal aqueous solutions. (See also J. Chem. Soc., May, 1918.)

—E. H. R.

Antimony tri-iodide; A new metastable form of —. A. C. Vournasos. Comptes rend., 1918, 166, 526–528.

A YELLOW amorphous form of antimony tri-iodide may be prepared by cooling a hot saturated solution of the red crystalline variety in glycerol, from which it is deposited in small yellow globules; by heating the red form on a water-bath with glacial acetic acid and a little potassium acetate; or by heating a mixture of antimony trioxide and potassium iodide at 100° C. with an excess of anhydrous acetic acid. This yellow form melts at 172° C. and at this temperature is converted into the red crystalline form. The last-mentioned method may also be used for the preparation of arsenic, antimony, and bismuth tribromides and arsenic and bismuth tri-iodides. (See also J. Chem. Soc., May, 1918.)—W. G.

Radium sulphate; Solubility of pure —. S. C. Lind, J. E. Underwood, and C. F. Whittemore. J. Amer. Chem. Soc., 1918, 40, 465–472.

IN the recovery of radium from its ores, the radium is always precipitated at some stage with barium in the form of sulphate. Information as to the completeness with which the radium is removed from solution by this process has been sought by measurement of the solubility of pure radium sulphate in water and in sulphuric acid solutions. It was found that 2.1×10^{-8} grm. RaSO_4 is dissolved by 1 c.c. of water at 25° C. The solubility is not affected by sulphuric acid up to a concentration of 50%. The solubility of radium sulphate is only about 1/100 of that of barium sulphate. This relationship does not account for the facts concerning the removal of radium from solution by precipitation with barium as sulphate, for the ratio of radium to barium in the precipitate is always the same as in the solution. (See also J. Chem. Soc., May, 1918.)

—H. M. D.

Iodine; Action of sodium sulphide on — and the use of the reaction in analysis. J. Ehrlich. Z. anal. Chem., 1918, 57, 21–22.

FREE iodine is dissolved by sodium sulphide solution with the formation of sodium iodide; sulphur is liberated by the reaction but soon dissolves again in the excess of sodium sulphide. To determine iodine in a waste product or residue containing an iodide and other substances, the iodine is liberated in the usual way with potassium permanganate, and dissolved in an excess of sodium sulphide solution; manganese sulphide, etc., is separated by filtration, the filtrate is treated with zinc sulphate to remove excess of sulphide, and the iodine is then precipitated as silver iodide.

—W. P. S.

Chlorine; Detection of small quantities of — in iodine. J. Pinkhof. Pharm. Weekblad, 1918, 55, 236.

THE presence of chlorine (between $\frac{1}{2}$ and 2%) in

iodine can be detected by treatment with thiosulphate, and precipitation of the sulphate formed by addition of barium nitrate.—A. J. W.

Argon; Industrial preparation of —. G. Claude. *Comptes rend.*, 1918, 166, 492—494.

AN application of the process of re-liquefaction. The mixture of oxygen, argon, and nitrogen resulting from the fractional distillation of liquid air, suitably compressed, is liquefied in a bath of liquid oxygen in such a way that the most volatile constituent, the nitrogen, passes on. The liquid mixture of oxygen and argon is then distilled, the gases passing up a column down which trickles some of the same liquid. The oxygen condenses and the argon passes on. By this means there is obtained a gaseous mixture containing 75—80% of argon and only 1—2% of nitrogen, the remainder being oxygen, which may be removed by burning it with hydrogen.—W. G.

PATENTS.

Silicic acid; Processes for making —. The British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 113,769, Nov. 9, 1917. (Appl. No. 16,456 of 1917.)

SILICIC acid in the form of a light voluminous powder is obtained by the action of an aqueous solution of an ammonium salt on water-glass; hydrated ammonium silicate, $\text{SiO}_2 \cdot \text{NH}_3 \cdot \text{H}_2\text{O}$, is precipitated, and the resulting mixture is then heated to the boiling point when the precipitated silicate gives off ammonia and yields silicic acid. The mixture is filtered, the precipitate washed thoroughly, then dried at 100° to 150° C. The product containing some 15% of water is passed through a 20- to 40-mesh sieve to remove coarse particles. The hydrated ammonium silicate may also be filtered off directly, and after washing, heated to about 150° C. when ammonia and water are given off. The silicic acid obtained by this process is particularly suitable for use as a fuse filler.—H. M. D.

Nitre-cake; Method for the utilisation of —. J. Grossmann, Manchester. Eng. Pat. 114,180, Mar. 19, 1917. (Appl. No. 3933 of 1917.)

THE nitre-cake, finely ground, is mixed with finely ground sodium nitrate and heated at 150° — 250° C., when the nitrate is decomposed almost quantitatively with the evolution of nitrous fumes. The proportion in which the substances are mixed will depend on the quantity of free sulphuric acid in the nitre-cake. The process may be carried on under ordinary, augmented, or diminished pressure, and air may be either excluded from or passed through the apparatus in which the decomposition takes place. If excluded from the decomposing vessel, the air may be mixed with the nitrous fumes subsequently, with formation of nitric and nitrous acids which may be used in the manufacture of sulphuric acid. The mixture may be placed on trays carried by trolleys which are introduced into the decomposing chamber at one end where the temperature is below 150° C. and discharged at the other end, the temperature of which is about 250° C.—H. M. D.

Ammonium sulphate and Glauber's salt; Process for the production and separation of —. H. M. Dawson, Leeds. Eng. Pat. 114,236, May 12, 1917. (Appl. No. 6767 of 1917.)

THE process relates to the separation of ammonium sulphate and Glauber's salt from the solution which is obtained by the absorption of ammonia in solutions of nitre-cake and other acid sodium sulphates. The concentration of the solution of ammonium and sodium sulphates is appropriately adjusted so that from 70 to 80 mols. of salt are present per 1000 mols. of water. The solution is then cooled to a sufficiently low temperature, when a large proportion of the contained sodium sulphate separates out in the form of Glauber's salt. In consequence of this crystallisation, the ratio of ammonium sulphate to sodium sulphate in the mother liquor is largely increased and when the mother liquor is evaporated at or about 100° C., pure ammonium sulphate separates out so long as the molecular ratio of ammonium sulphate to sodium sulphate in the hot mother liquor does not fall below about 2.7. When this stage is reached, the evaporation is stopped, and the residual liquor is suitably diluted and mixed with further liquor for treatment in the refrigerator. The presence of free acid in the solution from the saturator does not necessitate any essential modification in the cycle of processes, but it is advantageous to reduce the acidity as far as possible by the use of an efficient saturator. The proportion of free acid in the liquor may be further reduced by the addition of sodium carbonate or liquor ammonia before the concentration or adjusted to that value which is appropriate to the carrying out of the refrigeration process.—H. M. D.

[Iron] sulphate crystals; Method of recovering — [from pickling baths]. W. H. Sommer, Peoria, Ill., Assignor to The First Trust and Savings Co., Cleveland, Ohio, and W. E. Stone, Peoria, Ill. U.S. Pat. 1,256,068, Feb. 12, 1918. Date of appl., Sep. 20, 1915.

AFTER concentration by means of steam coils and air-agitation, the solution is allowed to settle, without cooling, to remove insoluble impurities, and then allowed to crystallise.—W. E. F. P.

Cyanides; Process for the synthetic production of — [by catalysis]. Process for the synthetic production of ammonia. P. A. Starke, Berkeley, Cal. U.S. Pats. (A) 1,256,272 and (B) 1,256,273, Feb. 12, 1918. Date of appl., Sep. 11, 1916.

(A) A MIXTURE of natural gas and ammonia is passed through a reactive mass heated to about 1000° C. The reactive mass is composed of suitable alkaline substances and a metal of the iron group, and is "devoid of carbon as a chemical reactive agent." (B) A mixture of natural gas and nitrogen (or atmospheric air) is treated as above at a temperature not higher than 800° C. and a pressure of not less than 7 atmospheres.—W. E. F. P.

Alkali metals; Process of replacing — in alkali-metal-carrying rocks and product thereof. H. W. Charlton, New York, Assignor to Kaolin Products Corporation. U.S. Pat. 1,256,295, Feb. 12, 1918. Date of appl., May 3, 1916.

FINELY divided sodium-potassium feldspar is heated with milk of lime and calcium carbonate at a pressure of not less than 200 lb. per sq. in., to form a product consisting of hydrous calcium aluminium silicate associated with a small proportion of calcium carbonate.—W. E. F. P.

Asbestos treatment; Process of — and product thereof. H. W. Charlton, New York. U.S. Pat. 1,256,296, Feb. 12, 1918. Date of appl., June 28, 1917.

A PRODUCT consisting of asbestos wool, the fibres of which are uniformly coated with lime, is obtained by heating asbestos wool with milk of lime under pressure.—W. E. F. P.

Barium sulphide; Purifying —. W. E. Prisk and H. R. Harrison, Halifax, Nova Scotia. U.S. Pat. 1,256,593, Feb. 19, 1918. Date of appl., May 31, 1917.

A SOLUTION of the barium sulphide is filtered through granulated manganese dioxide and afterwards through granulated calcium carbonate.
—H. M. D.

Nitrogen compounds of metals; Process of producing —. M. Sem, Assignor to Det Norske Aktieselskab for Elektrokemisk Industri, Norsk Industri-Hypotekbank, Christiania, Norway. U.S. Pat. 1,256,935, Feb. 19, 1918. Date of appl., Nov. 21, 1916.

THE carbide of the metal, in the form of fine dust, is introduced with nitrogen into a chamber, the temperature of which is raised sufficiently to start the reaction by making use of the heat evolved in the reaction between carbide and nitrogen previously introduced.—H. M. D.

Carbon for electrochemical, metallurgical, and other services; Manufacture of —. T. W. S. Hutchins, Middlewich, Eng. Pat. 113,812, Mar. 2, 1917. (Appl. No. 3113 of 1917.)

GROUND pitch or tar, alone or mixed with ground coke, coal, retort carbon, etc., is fed into the upper end of a closed, heated, vertical fireclay tube until the latter is filled with the carbonised product. The furnace is then allowed to cool, and the product withdrawn from the bottom of the tube in the form of a rod. For the preparation of carbon tubes, a smaller fireclay tube or rod is fixed within the larger one and the charge fed into the annular space. The density of the product is increased by conducting the carbonisation under pressure; for this purpose, and the recovery of volatile products, the fireclay tube is provided at each end with a valved outlet pipe.
—W. E. F. P.

Sulphuric acid; Concentrating —. J. W. Leitch, Huddersfield. U.S. Pats. 1,257,894 and 1,257,895, Feb. 26, 1918. Dates of appl., Dec. 14, 1915, and Oct. 11, 1917.

Manufacture of lampblack. Eng. Pat. 114,040. See XIII.

VIII.—GLASS; CERAMICS.

Glass; Tank-furnace for white — fired by gas from a coke-producer. A. B. Roxburgh. Soc. Glass Tech. Mar. 20, 1918. Gas J., 1918, 141, 586—587.

A PRODUCER of the natural draught type is built up to the tank so as to make use of the sensible heat of the gas. It has an inclined grate of bars of cruciform cross-section capable of rotation on their bearings so as to loosen and discharge ash. However turned, each bar will form a channel which can be kept filled with water from a pipe arranged to drip upon an exposed end. The bar is thereby cooled and the steam necessary to prevent clinker formation is supplied to the producer. The gas outlet is placed at the side of the producer and below the level of the top of the fuel bed. The working depth of the fuel bed is thereby maintained constant so long as the outlet is covered, and the producer need only be charged once in four hours. The gas passes through a dust-collecting chamber to the tank furnace, whence the products of combustion are removed from the opposite end and conveyed under the tank through recuperators to preheat the air supply and then to the chimney. One cwt. of gas coke free from breeze is consumed per hour, the storage capacity of the producer being about 4 cwt.—H. J. H.

PATENTS.

Annealing [glass, porcelain, metals] and apparatus used therein. A. Hilger, Ltd., and F. Twyman, London. Eng. Pat. 114,183, Mar. 19, 1917. (Appl. No. 3972 of 1917.)

A SAMPLE of the substance to be annealed, which may be glass, porcelain, or a metal, is formed into a rod, one end of which is inserted into a hole in a pillar and secured by means of a screw. A weight is attached to the other end of the rod, which is disposed horizontally. The apparatus is placed in the annealing chamber together with the articles to be annealed, and when the weight has sunk a certain distance it is known that the annealing process has reached a predetermined stage or is completed. The process can be carried out without measuring the temperature of the annealing chamber. The method is based on the fact that there is a relation between the disappearance of strain in a viscous substance and the deformation of the same substance under constant stress.
—H. M. D.

Glass-drawing furnace. G. L. Catlin and D. Morrison, Port Allegany, Pa., Assignors to R. W. Hilton, Smethport, Pa. U.S. Pat. 1,255,983, Feb. 12, 1918. Date of appl., May 19, 1917.

A GLASS furnace with an open top is fitted with a top stone having a depending annular flange, angular in cross section and with its lower edge extending horizontally. This flange engages with a movable pot-bottom the opposite faces of which are formed with a central plane portion with a diameter approximately equal to that of the flange and having a bevelled margin extending at an

angle to the lower edge of the flange and engaging with it. Springs are provided to keep the pot-bottom and flange in contact. Means are provided for raising and lowering the pot-bottom and for rotating it when lowered.—A. B. S.

Muffle leer [lehr]. H. M. Thompson, Washington, Pa. U.S. Pat. 1,257,150, Feb. 19, 1918. Date of appl., Oct. 1, 1917.

A MUFFLE chamber is superposed on a lehr chamber, with a horizontal division wall between. This wall consists of a number of spaced, parallel metal beams of inverted T-shape and plate-like tiles supported by adjacent beams. A number of baffle-walls resting on the beams divide the muffle chamber so as to produce a tortuous passage for the products of combustion.—A. B. S.

Ovens or kilns for use in the manufacture of tiles, pottery and other ware and for other purposes. J. H. Marlow, and Minton, Hollins, and Co., Stoke-on-Trent, Eng. Pat. 113,791, Dec. 4, 1916. (Appl. No. 17,366 of 1916.)

IN a tunnel oven, producer gas enters the oven through the duct, *a*, is mixed with hot air and burned in the combustion chambers, *b*, *b*¹, the flames and products of combustion passing through the longitudinal flues, *d*, *d*¹. Two further com-

bustion chambers (not shown) placed alongside *b*, *b*¹, deliver their products into the space, *c*¹, between the muffle arch, *c*¹, and the outer arch, *c*², of the oven and thence into the flues, *d* or *d*¹, respectively. Six such spaces are provided, the gases travelling in one direction through three of them and in the opposite direction through the other three so as to secure uniform heating. The curved sides, *d*⁴, of the flues, *d*, *d*¹, are provided with grooves on their outer faces and are covered by curved plates, *j*, forming a series of chambers through which hot air is drawn from the tunnel and superheated before it is allowed to come into contact with the goods, *a*, to be heated. Alternatively, the longitudinal flues, *d*, *d*¹, may have two sides of equal curvature, both of which are provided with air cavities, *j*. In the cooling zone of the kiln, the double arch, *w*, *c*¹, is placed a little distance away from the oven wall and its inner wall, *c*¹, is perforated, so that hot air may be drawn from the tunnel and through the space, *c*¹. This arrangement ensures rapid cooling without "dunting." The fire-zone of the oven has a covering, *y*, of non-conducting material.—A. B. S.

[Ceramic] ware dryer and factory. A. B. Klay, Modesto, Cal. U.S. Pat. 1,256,237, Feb. 12, 1918. Date of appl., June 10, 1916.

SEVERAL superposed drying compartments are

arranged over a burning kiln in the basement of the factory, and vertical flues from the kiln pass through the compartments and serve as heat-radiators. Elevators are provided to convey the ware downwards through the successive drying compartments to the burning kiln and upwards for delivery.—A. B. S.

Bricks and similar articles; Process of making —. S. J. Hayde, Kansas City, Mo. U.S. Pat. 1,255,878, Feb. 12, 1918. Date of appl., July 3, 1917.

A RAW argillaceous material containing a lime-producing substance is burned for a short time at a temperature exceeding 1500° F. (815° C.), cooled slowly, treated with water so as to slake the lime, crushed, mixed with cement and water, and moulded so as to form bricks or similar articles.—A. B. S.

Abrasives; Manufacture of artificial —. A. T. Snodgrass, Manchester, Eng. Pat. 113,731, June 23, 1917. (Appl. No. 9023 of 1917.)

Two or three parts of finely powdered natural emery or corundum, raw bauxite, or other material rich in alumina, is mixed with one part of finely powdered glass ("flour" glass), moulded into balls, and burned in a plumbago crucible at a temperature not less than 1700° C. The molten mass is poured on to a cool surface or otherwise allowed to solidify.—A. B. S.

Aluminous composition [abrasive] and method of preparing the same. O. Hutchins, Assignor to The Carborundum Co., Niagara Falls, N.Y. U.S. Pat. 1,257,350, Feb. 26, 1918. Date of appl., Nov. 14, 1917.

A CRYSTALLINE aluminous abrasive is made by fusing a mixture of bauxite, barium oxide or a compound yielding it, and carbon in an electric furnace, the carbon being present in sufficient quantity to reduce the major portion of the iron, silicon, and titanitic oxides present, but not the barium oxide.—A. B. S.

Valuation of lime for various purposes. Meade. See VII.

PATENTS.

Waterproof material for use in constructional purposes, as a substitute for leather, for street paving and the like. D. Volant, Bordeaux, France. Eng. Pat. 111,485, Nov. 13, 1917. (Appl. No. 16,674 of 1917.) Under Int. Conv., Nov. 21, 1916.

A STRONG homogeneous waterproof material is composed of superposed sheets of paper each impregnated by immersion in a hot bath of tar or asphalt, a suitable number of sheets being applied to one another so as to produce a material of the desired thickness. The mass is then heated to a suitable temperature whilst being passed between rollers so as to compress the material into a single sheet. For use in street pavements, asphalt is preferable to tar as an impregnating material, and the sheets should be set on edge.—A. B. S.

Waterproofed material [stone] and method of waterproofing. E. R. Jump, Newton, Mass. U.S. Pat. 1,256,324, Feb. 12, 1918. Date of appl., May 2, 1917.

AN insoluble salt is precipitated on the surface of the particles of a mass of gypsum in order to make it waterproof.—A. B. S.

Cement; Process of making —. E. C. Eckel, Washington, D.C., Assignor to A. C. Spencer, Washington, D.C., and A. Cox, New York. U.S. Pat. 1,255,995, Feb. 12, 1918. Date of appl., Apr. 17, 1911. Renewed Jan. 3, 1918.

DIATOMACEOUS earth is added to a cement mixture containing iron and calcareous material so as to bring the total silica up to a desired ratio to the ferric oxide present. The clinker should contain an amount of combined silica more than twice that of the sesquioxides present.—A. B. S.

Wood impregnation. G. G. Carver, Assignor to The Jennison-Wright Co., Toledo, Ohio. U.S. Pat. 1,256,200, Feb. 12, 1918. Date of appl., May 20, 1915.

THE wood is submerged in a preserving fluid, and subjected to pressure, which is afterwards relieved and the excess of fluid removed. It is then immersed in an impregnating fluid under a lower pressure than that applied in the previous operation. Alternatively, the wood may be subjected to gas pressure and, without relieving this, may be treated in a bath of preservative substance under a still higher pressure. The surplus preservative is then removed and the wood subjected to a partial vacuum and afterwards impregnated by immersion in a suitable liquid under a lower pressure than that employed with the preservative fluids.—A. B. S.

Impregnating wood; Apparatus for —. J. H. Parsons, Assignor to W. H. Savery, Wilmington, Del. U.S. Pat. 1,257,923, Feb. 26, 1918. Date of appl., Nov. 11, 1916.

A CYLINDER is provided with a socket to receive one end of the log or piece to be treated, this socket being in communication with the atmosphere. The other end of the log is fitted into a socket attached to a piston which slides within the cylinder so as to clamp the log in the required position. The impregnating fluid is supplied under pressure to the interior of the cylinder.—A. B. S.

Mineral wool; Means for making —. W. Fay, St. Louis, Mo. U.S. Pat. 1,256,511, Feb. 19, 1918. Date of appl., Mar. 3, 1917.

A STREAM of molten scoria is discharged from a cupola into a combined blast pipe and mixing chamber, and a blast of steam mixed with a dust-settling fluid is directed into it so as to form wool-fibres. The mixture passes into a chamber, in which the mineral wool fibres are collected, this chamber being provided with restricted outlets so as to maintain pressure therein.—A. B. S.

Wood; Preservation of — and production of substances therefor. W. P. Thompson, Liverpool. From P. C. Reilly, Indianapolis, Ind., U.S.A. Eng. Pat. 114,181, Mar. 19, 1917. (Appl. No. 3917 of 1917.)

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Steels; Quenching and work-hardening of carbon —. F. Cloup. Comptes rend., 1918, 166, 415—416.

THE heating curves of quenched or work-hardened

steels show an irregularity at 400° C. characterised by an evolution of heat. The change of state occurring at that point only proceeds slowly in either case, but it is irreversible, cooling curves in both cases being smooth and regular. For example, specimens of a steel containing 0.12% C were quenched from 1000° C. in water at 15° C. and cold-hammered respectively, and each was heated at 610° C. for 25 mins. Each specimen still showed the break in the heating curve during a second reheat, but after this had been continued for 12 hrs. at 600° C. transformation was complete and the heating curves showed no irregularity.—W. G.

Tantalum; Estimation of — in its alloys with iron. Travers. Comptes rend., 1918, 166, 494—495.

THE steel is treated with *aqua regia* and the tantalic acid is separated by two successive evaporations. In the case of ferro-tantalums the material is fused with anhydrous sodium sulphate and the mass is extracted with dilute acid. In either case the impure tantalic acid is fused with pure potassium hydroxide, the melt is extracted with water, and the filtrate acidified with very dilute sulphuric acid and boiled for one hour. The tantalic acid, contaminated with a little silica, is weighed and then heated in a current of hydrogen chloride at 900° C. This process removes the whole of the tantalic acid and leaves behind all the silica, which may be weighed and thus allowed for. If chromium is present a little sodium peroxide is added to the potassium hydroxide prior to the fusion. Tungsten, if present, is separated after the precipitation with dilute acid by washing the precipitate with a large excess of ammonia solution. (See also J. Chem. Soc., May, 1918.)—W. G.

Platinum substitute [platinum-gold alloy]. I. L. B. van der Marck. Pharm. Weekblad, 1918, 55, 149—151.

AN alloy containing about 11% Pt and 89% Au is being made under the trade name "Platino." Experiments show the alloy to be very resistant; it is, however, attacked by sulphuric acid containing nitric acid, but is more resistant to caustic potash than platinum. On heating in a smoky flame, it does not become brittle, as is the case with platinum. Its resistance to fused potassium nitrate obviates the necessity of using porcelain vessels for fusions. The cost is about one-third that of pure platinum.—F. W. A.

Copper; Progress in the metallurgy of —. H. C. H. Carpenter. J. Royal Soc. Arts, 1918, 66, 114—123, 128—137, 141—153.

A COPPER smelter was in operation near Keswick in 1580. The Mines Royal Society, which was constituted in that year, started smelting in Wales at Neath; 100 years later two other companies began operations at Melinerebyn and Taibach. The first smelters in the Swansea district were erected in 1717. The ores smelted in Wales were mined in Cornwall and Anglesey. During the 17th century the reverberatory furnace was evolved in Wales, all previous copper smelting having been carried out with charcoal in small shaft furnaces. The coal consumption in the Welsh process was over 18 tons per ton of metal produced. The English copper industry reached its zenith during the middle of the 19th century, but the arbitrary methods in buying ores and selling metal, pursued by the Associated Copper Smelters (the Welsh combiné) led to the introduction of smelting in Chile, which had already become the most important ore producer. In the decade 1861—70, Chile led the world's output; at the same time, mining operations at Calumet,

Mex., U.S.A., were greatly increased, while Spain, Portugal, and Australia became important producers. The Rio Tinto mine passed under English management in 1876. From 1880, the United States became the foremost copper producer, while Chile declined; Japan introduced up-to-date smelting processes. At the end of last century the United States produced more than 50% of the world's copper; the bulk of the output was derived from Arizona, Montana, Michigan, and Utah. The old Welsh, the Rio Tinto, and the pyritic processes are briefly described, as are also those used at Chuquibambilla and Anaconda, including the following changes made at the latter plant in 1914–15. The slimes are treated in machines of the Minerals Separation type with 4–8 lb. of sulphuric acid, 2–3 lb. of kerosene sludge acid, and $\frac{1}{2}$ –1 lb. of crude wood creosote per ton of feed. The latter assays 2.3–2.6% Cu, the flotation tailing 0.25%. By the adoption of flotation, the concentrator recovery has been raised from 76 to 95%. The flotation concentrate is filter-pressed, roasted, and smelted in reverberatories. The flue gases from the roasting-furnaces are treated by the Cottrell electrostatic process, which recovers 70 tons of dust per 24 hours from 1500 tons of concentrate. The new sand-leaching plant treats mill tailings as well as old dump material. This is roasted with salt and leached by downward percolation with a hot solution of salt and sulphuric acid. The liquors are precipitated with scrap-iron. The acid is made on the spot from the roaster gases. The process recovers 85% of the copper and 93.5% of the silver. The reverberatory smelting furnaces have been reconstructed and are now fired with coal-dust, whereby the output of each furnace has been more than doubled, while the fuel ratio, i.e., ratio of charge to coal, has increased from 4.2 : 1 to 6 : 1. A description of the coal-pulverising plant is also given.—W. R. S.

Nitric acid and copper ore. G. C. Westby. *Met. and Chem. Eng.*, 1918, 18, 290–296.

AN unsuccessful trial of a process of copper extraction from a sulphide ore is recorded. Pulverised ore was added at a carefully regulated rate to warm dilute nitric acid, the temperature being maintained by blowing in steam as required when the violence of the reaction had subsided. Agitation was effected by compressed air which also re-oxidised to nitrogen peroxide the nitric oxide evolved. The nitrous gases with excess of air were blown forward through a train of towers, where they were absorbed in water and nitric acid regenerated for use on fresh ore. Copper and iron were obtained as sulphates, and the solution was filtered and treated in the usual manner. Ten laboratory experiments showed an average recovery of copper of 88.9% and of nitric acid equal to 90.5%. The loss of nitric acid was due to imperfect recovery and also to loss in the liquors as nitrates of iron and copper. On a manufacturing scale the recovery of copper and nitric acid was much less satisfactory—67.2% and 75.7% respectively—and without an almost complete recovery of nitric acid the process is not feasible commercially.—H. J. H.

Muntz metal (60 : 40 brass); Typical cases of the deterioration of — by selective corrosion. H. S. Rawdon. U.S. Bureau of Standards, Technol. Paper 103, 1917. 28 pages.

By selective corrosion is meant that type of deterioration which is brought about by electrolytes (e.g., sea water) through the attack of certain microstructural constituents of the alloys leading, in the present instance, to "dezincification." Typical cases of such corrosion of Muntz metal

have been examined, including bolts and sheathing from the keels of sea-going boats, and condenser tubing. The paper is illustrated with numerous photomicrographs of the specimens described. Normally, the structure of Muntz metal consists of a matrix of β constituent, relatively rich in zinc, in which are embedded crystals of the α constituent which is poorer in zinc. In all cases the β constituent is attacked first, the rate at which the α constituent is attacked being variable and sometimes indefinitely delayed. The metal when thus attacked becomes red in appearance, like poor copper, and is very weak and porous. The micrographs show that the attack on the β phase is not a gradual one but is abrupt and complete, the line of demarcation between the attacked and unattacked portions being very sharp. Dezincification may also occur in a brass, but the method of attack is different. Samples which have been heat-treated have an outer layer of α -brass from which excess of zinc has volatilised, and this layer serves as a protective coating for the α - β alloy beneath. The author's experiments do not show any relation between time or temperature of annealing of the metal and susceptibility to attack by salt solution. The character of the surface may be of importance, since at those points where specks of basic zinc chloride accumulate, corrosion is specially rapid. Other influences which may accelerate the rate of attack are contact with substances more electronegative than either α or β constituent, an increase of temperature, or localised stresses. Whilst the results of the author's experiments suggest that highly localised stresses increase the susceptibility to attack, they are not regarded as conclusive.—E. H. R.

Bronze; An investigation of unsound castings of Admiralty — (88 : 10 : 2); its cause and the remedy. H. C. H. Carpenter and C. F. Elam. *Inst. of Metals*, March, 1918. [Advance copy.] 21 pages.

WHEN Admiralty bronze is poured at 1400° C., unsound castings are always obtained, due to the presence of blowholes. Pouring below 1100° C. very often causes unsoundness. The metal is always sound if left to cool in the crucible, even if overheated; this also applies to previously cast unsound metal. Hence the temperature of casting is the deciding factor. The blowholes are formed by the liberation of dissolved gases. These were collected *in vacuo* and analysed: they were found to consist of typical furnace gases, whether the castings were sound or unsound. No constant or sufficient difference in the volume of gas could be found to account for the presence or absence of blowholes. Pure copper heated *in vacuo* yields gas resembling that obtained from bronze, hence the gases which cause unsoundness are very probably derived from the copper itself, especially as they are most difficult to expel. The best way of avoiding unsound castings is to control the temperature before pouring, so that it is within the interval 1270°–1150° C.—W. R. S.

Aluminium; Annealing of —. R. J. Anderson. *Inst. of Metals*, Mar. 14, 1918. [Advance copy.] pp. 3 and 1 plate.

FIVE specimens of aluminium sheet (16 gauge) were subjected to chemical and microscopical examination. The iron content (0.74 to 0.90%) was higher than usual in American metal of good quality. Shore hardness numbers varied from 6 to 9, whereas the usual numbers for such sheet are 13–15 in the severely worked specimens and 4–5 in annealed specimens. The samples in question had probably been partly annealed after cold rolling. The metals were found to be almost structureless or with crystals deformed

in the direction of work. On annealing at 540° C. for 15 mins. followed by slow cooling a typical structure was developed. Excessive initial deformation appeared to retard crystal growth. (For the polishing and etching of aluminium see this J., 1918, 211 A.)—H. J. H.

Aluminium-copper alloys; Constitution of the copper-rich—. J. N. Greenwood. Inst. of Metals, March, 1918. [Advance copy.] 46 pages.

THE relation between the hardness and composition of alloys containing less than 16% Al was investigated by the Brinell and scleroscope methods, the former being more satisfactory on the whole. The hardness-composition curve of the α -series of solid solutions (up to about 9.7% Al) was found to be linear. Hence the idea that the upper limit of this series of solid solutions is formed by the compound, Cu_4Al , cannot be maintained. The curve for the quenched β -series of solid solutions showed a minimum at 12.5% Al, which confirms the existence of Cu_3Al . In the case of alloys containing $\alpha + \bar{c}$, $\alpha + \beta$, or $\beta + \bar{c}$, there is a marked deviation from the linear relationship between hardness and composition. Alloys with 8.7–13.3% Al reached a state of phase equilibrium after 20 days at 600° C. The results of a separate investigation of β will shortly be published.

—W. R. S.

Aluminium-bronze; Die-casting of—. H. Rix and H. Whitaker. Inst. of Metals, March, 1918. [Advance copy.] 9 pages.

THE advantages of aluminium as a die-casting metal are its low sp. gr., cheapness, and strength. Its chief drawbacks are high melting-point and shrinkage, weakness at high temperatures, and the tendency of the molten metal to attack iron. The high shrinkage can be reduced by alloying, and need not exceed about 1.4%. Aluminium-bronze containing about 10% Al does not give well-defined edges, but much better results are obtained if 1–4% Fe is added. The mechanical properties may be profoundly modified by heat treatment; the temperature of the molten metal and die should be known, and the rate of cooling of the casting standardised. The dies are made of close-grained cast iron, as hard as is consistent with good machining properties. From 5000 to 7000 castings can be made before the die shows signs of deterioration.—W. R. S.

Metals; Velocity of dissolution of— in acids. III. Velocity of dissolution of alloys of zinc with arsenic, lead, cadmium, nickel, platinum, and gold. M. Centnerszwer. Z. physik. Chem., 1918, 92, 563–580.

THE rate at which zinc dissolves in hydrochloric acid (compare this J., 1917, 292) is not increased when the metal is alloyed with small quantities of arsenic, lead, or cadmium. On the other hand, very small quantities (0.01%) of nickel, platinum, or gold produce a marked increase in the rate at which the zinc is attacked by acids. It seems probable that pure zinc will not react at all with hydrochloric or sulphuric acid if the concentration is less than 0.5–1 N. (See also J. Chem. Soc., May, 1918.)—H. M. D.

Lead-tin-antimony alloys. O. W. Ellis. Inst. of Metals, March, 1918. [Advance copy.] 4 pages.

THE general mechanical properties of alloys containing less than about 15% Sn were improved by the addition of antimony in quantities not exceeding 10%. An increase in the antimony content led to increased hardness, though there

appeared to be a region of maximum hardness in the vicinity of the 70:10:20 alloy. On the whole, the alloys were brittle and weak.—W. R. S.

Alloys; Theoretical and experimental researches on metallic—. N. Parravano. Annali Chim. Appl., 1918, 9, 1–86.

A RESUMÉ of the author's investigations on alloys, including theoretical studies on ternary and quaternary alloys. The systems which have been studied experimentally include Sn—As (this J., 1911, 1018), Sb—As (this J., 1912, 495), Sb—Se, Bi—Se, Mn—Zn (this J., 1915, 286), Mn—Bi (this J., 1915, 802), Sb—K, Cu—Zn (this J., 1915, 86), Ni—Mn—Cu and Fe—Mn—Cu (this J., 1912, 1131), Fe—Ni—Mn (this J., 1912, 1081), Cu—Au—Ag and Ni—Cu—Au (this J., 1914, 261), Ni—Au—Ag (this J., 1913, 1158), Ni—Cu—Ag (this J., 1913, 1112), Ni—Cu—Pb (this J., 1914, 1212), Cu—Zn—Pb (this J., 1915, 86), Ag—Pb—Sn (this J., 1911, 1120), Cu—Sb—Bi, Pb—Sn—Cd—Bi (this J., 1912, 778), Fe—Ni—Mn—Cu (this J., 1913, 89), and Ni—Cu—Au—Ag (this J., 1914, 1092).

Flotation; Effect of addition agents in—. III. M. H. Thornberry and H. T. Mann. Met. and Chem. Eng., 1918, 18, 249–252.

THE experiments previously described (this J., 1918, 93 A, 153 A,) have been extended to include the use of chlorides. Chlorides of alkalis and alkaline earths, and hydrochloric acid reduce slightly the extraction and grade of concentrate. The effect of chlorides of the heavy metals is on the whole similar but more erratic. Silver chloride had a marked effect on the extraction when cresylic acid was used. Very detrimental effects on both extraction and grade of concentrate were noted with stannous chloride and uranium chloride, and in this respect cadmium chloride behaved similarly to the other salts of this metal. The froths were uniform and composed of small or medium-sized bubbles which broke up easily.—H. J. H.

Slag viscosity tables; Blast furnace—. A. L. Feild and P. H. Royster. Amer. Inst. Min. Eng., Feb. 18, 1918. Blast Furnace and Steel Plant, 1918, 6, 117–120.

THE method of measuring the viscosity of liquid slags already described (this J., 1918, 61 A) has been applied to typical blast-furnace slag mixtures. Provided that minor constituents are not present in abnormal quantities and that the MgO content does not exceed 8%, the viscosity was found to be a function of the relative percentages of lime, alumina, and silica. Tables have been constructed to cover the slag viscosities of such ternary mixtures over a wide range of variation of composition and temperature (U.S. Bureau of Mines Tech. Paper 187). In the present paper the application of these tables to blast-furnace problems is discussed. Low viscosity at low temperatures is favourable to fuel economy. High viscosity necessitates high working temperature and therefore favours the reduction of silica as in the manufacture of foundry iron. Thus high alumina content of slag favours the production of high-silicon pig. A long temperature range of the pasty stage conduces to lengthy contact of metal and slag and so favours desulphurisation in the basic pig process. The tables show that slight changes in composition sometimes cause a marked change in the viscosities of slags, emphasising the necessity for accurate adjustment of the burden and the chemical control of slags.—H. J. H.

Spectroscopic detection of boron [in steel and in minerals]. De Gramont. See XXIII.

Steel; Manufacture of—[in electric furnaces]. C. A. Keller, Paris. Eng. Pat. 113,635, Feb. 17, 1917. (Appl. No. 2391 of 1917.)

A QUANTITY of iron and steel turnings or similar light waste metal is subjected to desulphurising fusion in one or more electric furnaces to obtain a crude metal of approximately the desired composition, and this is transferred to a finishing furnace, which may be either a Martin furnace or an electric furnace. The melting furnace is kept full of turnings, mixed with a basic slag, and casting is effected at intervals. A proportion of carbon exceeding the final amount desired may be added to the metal in the melting furnace, so that the desired final content can be readily attained in the finishing furnace in which dephosphorisation is effected.—T. H. B.

Metals [iron and steel]; Refining of—. J. H. Beckett, Birkenhead. Eng. Pat. 113,834, Mar. 8, 1917. (Appl. No. 3414 of 1917.)

AIR is forced at a pressure of 20 to 80 lb. per sq. in. into the metal while in a furnace of the "mixer" type, through tuyères which pass down obliquely through the surface of the metal. The tuyères are protected by a fire-resisting medium or are cooled by water. The partial elimination of silicon, manganese, carbon, and phosphorus is thereby effected.—T. H. B.

Iron sponge; Treatment of—. A. Sinding-Larsen, Christiania, Norway. Eng. Pat. 114,025, Mar. 14, 1917. (Appl. No. 3722 of 1917.)

IRON sponge is treated with carbon monoxide at about 100° C., and at the same time subjected to a rubbing or disintegrating action; the vapours of iron carbonyl thus produced are brought into contact with a thin iron core forming the secondary of an electrical induction furnace, so heated that the iron carbonyl is decomposed and iron deposited on the core. The iron thus obtained is further carburised by heating at a higher temperature in presence of hydrocarbons. Nickel steel may be obtained by adding nickel carbonyl to the iron carbonyl before passing it into the induction furnace.—T. H. B.

High speed steel; Process [and flux] for welding—to other steel or iron. A. F. Beanlien, Chicago, Ill. U.S. Pat. 1,256,429, Feb. 12, 1918. Date of appl., Dec. 21, 1915.

A FLUX for use in welding metals containing different percentages of carbon consists of sodium bicarbonate 40%, sodium carbonate 40%, sodium borate 10%, precipitated silica 5%, lithium carbonate 5%.—T. H. B.

Magnetic iron ore; Separation of—from its associated non-magnetic or feebly-magnetic minerals. D. M. Barringer, Wayne, Pa. U.S. Pat. 1,256,972, Feb. 19, 1918. Date of appl., May 10, 1911. Renewed July 17, 1917.

MAGNETIC material is separated from non-magnetic or less magnetic substances by conveying the mixed materials by water down an inclined trough of substantially non-magnetic material of high electrical conductivity, and subjecting the substances to the influence of a magnetic flux. The water separates the particles and reduces the friction of the same on the trough and on each other. The magnetic flux is created by an electromagnet, on the under side of the plate or trough, which is energised by an alternating current. The magnetic materials are diverted from their normal path of travel, passing towards and over the edges of the trough.—B. N.

Composite bi-metallic articles [thermostatic metal]; Manufacture of—. The British Thomson-Houston Co., Ltd., London, From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 113,758, Sept. 18, 1917. (Appl. No. 13,406 of 1907.)

A BAR of "invar" (Ni 35.5%, C 0.18%, Mn 0.42%, Fe 63.9%) contained in a mould is heated to bright redness, and a flux (e.g., borax) applied to the surface; one end is then brought to a fusing temperature and brass melted upon it to alloy with the "invar." This "brassing" is continued until the entire upper surface of the bar has received a uniform layer of brass, about $\frac{1}{8}$ -inch thick. While the brass layer is in the molten condition sufficient molten brass is poured into the mould to produce the desired thickness in the composition ingot, which is afterwards passed through suitable rolls and reduced to the required dimensions; lead-free brass is used.—T. H. B.

Tungsten ingots and the like; Method of and apparatus for welding or sintering—. M. J. Insull, Chicago, U.S.A. Eng. Pat. 113,835, Mar. 8, 1917. (Appl. No. 3422 of 1917.)

TUNGSTEN ingots or the like are sintered whilst subjected to a continual longitudinal pressure between electrodes, the ends of the latter being maintained perfectly parallel during longitudinal movement, so as to produce a straight bar or ingot which is held in position horizontally by the electrodes. A portion of the electrodes at least is composed of tungsten treated with carbon, and the electrodes, which are maintained under spring pressure, are of the same, preferably square, cross-section as the ingot. The electrode supports extend from or are supported by a stationary head or cover, which co-operates with a movable chamber to hold the ingot substantially horizontally between them, and the chamber is pressed by a device firmly against the cover to form a gas-tight chamber. One of the electrode supports is provided with a guide and guided portion, by which that electrode may be moved towards or away from the other whilst still maintaining parallelism of the electrode ends, a flexible conductor being provided and having off-set parallel portions connecting the guided portion of the electrode support with the guide portion.—B. N.

Tungsten powder and the like; Compressed—and method and apparatus for producing the same. M. J. Insull, Chicago, U.S.A. Eng. Pat. 113,836, Mar. 8, 1917. (Appl. No. 3423 of 1917.)

MALLEABLE tungsten articles are produced by first compressing tungsten powder to an unsintered form of a strength substantially equal to that of blackboard chalk and with sp. gr. about 17.25, by a pressure of from 135 to 160 tons per sq. in. and then relieving the pressure so that the compressed powder expands substantially equally in all directions. For this purpose a female die is formed of a movable lining seated in a die block, comprising four separate die members, two of which are preferably rigidly connected together, or two members may be formed with recesses in which the other two members engage, the block with the four die members forming five plane walls of a rectangular chamber with diverging walls in which the tungsten powder is compressed by the co-action of the male die. When the latter is withdrawn after compression, the slight lateral movement of the walls of the lining is such as to make the lateral expansion of the chamber about the same as the vertical enlargement.—B. N.

Furnaces; Electric — [for manufacture of tungsten powder]. M. J. Insull, Chicago, U.S.A. Eng. Pat. 113,839, Mar. 8, 1917. (Appl. No. 3426 of 1917.)

A FURNACE for the reduction of metallic oxides, particularly for the reduction of tungsten trioxide to metallic tungsten powder, is formed from a refractory silica tube, provided along part of its length only with a thin sheet nickel lining for protection from injurious chemicals, especially tungsten suboxides liberated during the reduction process. The tube is surrounded by a heating element, and a rapid current of hydrogen, preheated to a temperature substantially equal to that at which the material is maintained for reduction, is passed over the tungsten trioxide or other metallic oxide in the tube, preferably at a pressure exceeding that of the atmosphere. The hydrogen and metallic oxide are maintained at a substantially constant temperature throughout the length of the reducing portion of the furnace. The heating element for the hydrogen is arranged near the point where the gas enters the tube, and comprises a ribbon of conducting material, preferably nichrome, loosely wound upon a central support, each convolution being formed so as to engage the support and to extend away from the support substantially to the inner wall of the furnace. This form is secured by winding the element spirally about a flat mandrel, withdrawing the latter and permitting the element to uncoil, when it is afterwards secured to a central support within the furnace. A gas spreader is arranged near the point of entry so as to prevent the formation of stationary gas pockets about the heating element.—B. N.

Gas-fired furnaces, oil-fired furnaces, and the like [for heating and melting metals]. I. Hall, Birmingham. Eng. Pat. 114,177, Mar. 15, 1918. (Appl. Nos. 3746, Mar. 15, 1912, Mar. 19, and 12,201, Aug. 25, 1917.)

A FURNACE for melting metals, or heating bars, shells, etc., fired by means of one or more oil or gas burners, is provided in its upper part with a metallic conduit in which the air or mixture of air and fuel is preheated. This conduit is completely embedded in the refractory lining of the furnace in such a manner that a certain thickness of refractory material lies between the conduit and the heating chamber to protect the conduit from contact with the flame. The outlet from the conduit is connected to the gas or oil burners which heat the furnace. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 25,106 of 1906 and 103,232; this J., 1917, 200.)—J. H. P.

Aluminium; Solder for —. J. J. Aubertin, jun., St. Louis, Mo. U.S. Pat. 1,256,285, Feb. 12, 1918. Date of appl., Oct. 15, 1917.

The solder is composed of two parts of zinc to one of tin with a relatively small proportion of sal ammoniac (ammonium chloride).—T. H. B.

Ores; Reduction of —. S. Westberg and E. Edwin, Christiania, Norway. U.S. Pat. 1,256,623, Feb. 19, 1918. Date of appl., Aug. 26, 1916.

CARBONACEOUS material, and a gas containing combined oxygen, e.g., carbon dioxide and water vapour, are subjected to a high-tension electric arc, and the resulting carbon monoxide and hydrogen used to reduce an oxide ore.—T. H. B.

Ore-concentration process. B. H. Dosenbach, Butte, Mont. U.S. Pat. 1,257,329, Feb. 26, 1918. Date of appl., Nov. 16, 1917.

A MIXTURE of air with a "modifying agent" in

the form of a fog is introduced through a porous medium of fine texture into an ore pulp; certain mineral particles adhere to the bubbles formed as they rise through the pulp, forming a column of bubbles above the pulp.—T. H. B.

[Hot-blast furnaces;] Operation of chequer-brick heaters [for —]. A. Pföser, Achern, and O. Strack, Saarbrücken, Assignors to Gebr. Stumm, G.m.b.H., Neunkirchen, Germany. U.S. Pat. 1,257,524, Feb. 26, 1918. Date of appl., Aug. 26, 1913.

IN heating chequer-work brick heaters of the regenerative type for hot-blast furnaces, the transfer of heat from the hot gases to solid surfaces is promoted by violent agitation and increased velocity of the hot gases. This is obtained by introducing hot blast-furnace gas and air in quantities largely in excess of that normally passing through the heater to the stack, so that all particles of gas are brought into frictional contact with the walls of the chamber.—W. F. F.

Precious metals; Process of extracting — from ores containing alkaline-earth carbonates, etc. J. G. Kirchen and D. B. Bradner, Tonopah, Nev. U.S. Pat. 1,257,612, Feb. 26, 1918. Date of appl., Aug. 8, 1917.

ORE containing calcium carbonate and other alkaline-earth carbonates is roasted at a temperature exceeding 600° F. but less than 1200° F. (315°–650° C.) so that the carbonates are not decomposed to oxides, and the roasted ore is then subjected to cyanide treatment.—T. H. B.

Iron sponge; Production of — from iron ore. A. Sinding-Larsen, Vestre Aker, Norway. U.S. Pat. 1,256,939, Feb. 19, 1918. Date of appl., Mar. 21, 1917.

XI.—ELECTRO-CHEMISTRY.

Alternating current electrolysis [of sodium thiosulphate] with mercury electrodes. H. B. Weiser. J. Phys. Chem., 1918, 22, 78–94.

WHEN an alternating current is passed through a solution of sodium thiosulphate between mercury

electrodes, the electrodes are corroded and mercuric sulphide is precipitated. The yield of sulphide decreases as the frequency of alternation increases. Similar effects are obtained with other metal electrodes, but with mercury the effects are distinguished from those with solid metals in that reproducible results are obtainable. The electrolytic yield increases with the concentration of the thiosulphate solution, provided that this is not large enough to produce a film of sulphide which cuts down the corrosion very considerably, and also with the current density. Rise of temperature also causes a slight increase in the electrolytic yield. The experiments were made with a current alternating 7200 times per minute. (See also J. Chem. Soc., May, 1918.)—H. M. D.

PATENTS.

Furnaces; Control and regulation of electric —. Brown, Boveri, and Co., Ltd., and A. Gray, London. Eng. Pat. 113,827, Mar. 6, 1917. (Appl. No. 3318 of 1917.)

THE furnace is controlled by automatic variation of the length of the arc, a motor-generator combination being so arranged that the power supplied to the motor is proportional to the variation in the predetermined current input of the furnace, and regulation being effected without making or breaking any of the controlled circuits during the period of automatic regulation. The direct current motor is supplied with current from a separately excited direct current generator, the current being controlled by an automatic regulator having a rotating field, influenced by any variation in the working current, and an additional spring control. A variable non-inductive resistance, in parallel or in series with the electro-magnetic field system of the automatic regulator, is provided for readjusting the current input to any desired value. A number of electrodes may be operated by a single motor responsive to the variations in the average current taken by the furnace.—B. N.

Furnace; Electric heating —. *Method of heating*. E. E. Walker and J. W. Cox, Erie, Pa. U.S. Pats. (A) 1,256,958 and (B) 1,256,959, Feb. 19, 1918. Dates of appl., (A) Jan. 2, 1917. Renewed July 11, 1917, (B) Feb. 15, 1917.

(A) AN electric heating furnace comprises a heat-diffusing electrode, which is liquid under the heat of the arc, a supporting floor for the material to be treated, and an enclosing wall including a space of greater area than the electrode, the wall being in such a position that it receives and deflects the heat from the liquid electrode. A second electrode is arranged to act with the liquid electrode for completing the arc. (B) An electric arc is formed, and the heat taken up, diffused, and communicated through the medium of a liquid electrode, which is melted by the heat of the arc, the matter to be heated being independent of the liquid electrode.—B. N.

Electrical contacts [of tungsten or tungsten alloys]. M. J. Insull, Chicago, U.S.A. Eng. Pat. 113,838, Mar. 8, 1917. (Appl. No. 3425 of 1917.)

AN electrical make and break contact, of pure tungsten or tungsten alloyed with other rare metals such as molybdenum, is made by cutting a disc of metal from the end of a rod which is drawn, or which has the grain thereof running lengthwise of the rod, the grain being thus perpendicular to the contact face.—B. N.

Resistance element; Electric —. G. M. Laird, Assignor to L. B. Lincoln, Chicago, Ill. U.S. Pat. 1,257,272, Feb. 19, 1918. Date of appl., May 19, 1916.

AN element formed of an alloy of nickel, cobalt, and silicon, containing at least 75% Ni.—B. N.

Primary cells; Galvanic —. R. Schuster, Puppiling, Germany. Eng. Pat. 114,012, Mar. 12, 1917. (Appl. No. 3584 of 1917.)

A TWO-FLUID cell contains zinc in caustic alkali, and carbon in an aqueous solution of potassium or sodium bichromate or permanganate to which is added a large excess of concentrated sulphuric acid.—B. N.

Electrolytic apparatus. H. T. Shriver, West Orange, N.J. U.S. Pat. 1,256,067, Feb. 12, 1918. Date of appl., Jan. 20, 1916.

AN electrolytic cell of the filter-press type comprises a number of flat plates held face to face, the plates being recessed to form a cell between adjacent faces, with a diaphragm between. Each plate is provided with a U-shaped duct formed in the walls, one arm being relatively short and connected to the recess, and the other relatively long and opening to the outside of the plate. A constantly running supply of diluent is supplied to the long arm at a faster rate than that of exhaustion from the cell, the long arm being so arranged that the excess overflows after a predetermined level has been reached, thus keeping the liquid at a constant pressure.—B. N.

Electrolytic cell. T. G. Hitt, Seattle, Wash. U.S. Pat. 1,256,319, Feb. 12, 1918. Date of appl., Oct. 26, 1917.

THE receptacle containing the electrolyte is provided with a cover from which boxes hang side by side, vertical grooves in the adjacent faces registering together, and registering with grooves in the cover. Carbons pass through the apertures made by the grooves. Each box is provided with a vertical slot containing anode material, and wires connect the electrodes with a source of electricity, the connections with the anode material being within the boxes, which are sealed to protect the connections from electrolytic action.—B. N.

[*Electric battery plate separators.*] *Composition of matter*. J. Becker, Chicago, Ill. U.S. Pat. 1,256,861, Feb. 19, 1918. Date of appl., Nov. 27, 1916.

SEPARATORS for battery plates are formed from a pasty mixture of powdered volcanic ash (50 parts), powdered calcium sulphate (40 parts), and sulphuric acid, sp. gr. 1.285—1.357 (50 parts), in conjunction with a base of asbestos fibre (1 part).—B. N.

Manufacture of carbon for electrochemical, metallurgical, and other services. Eng. Pat. 113,812. See VII.

Electric furnace [for the manufacture of tungsten powder]. Eng. Pat. 113,839. See X.

Process of refining sugar. U.S. Pat. 1,253,758. See XVII.

XII.—FATS; OILS; WAXES.

Sesamé oil reaction; Modified —. F. Weehuizen. Pharm. Weekblad, 1918, 55, 77—79.

THE work of Van Ekenstein and Blanksma (this J., 1909, 536) showed that β -hydroxy- α -methylfurfural, and not furfural, is formed by the action of hydrochloric acid on hexoses; in a later paper Blanksma (this J., 1910, 833) states that the product is ω -hydroxymethylfurfural, the aldehyde

corresponding to 2-hydroxymethylfuran-5-carboxylic acid. The substitution of furfural for the sugar in Baudouin's reaction for sesame oil is therefore incorrect. This reaction is carried out by shaking a small amount of solid or liquid levulose (sucrose may be used) with 3—5 c.c. of a fully saturated alcoholic solution of hydrochloric acid for about 1 min., adding an equal volume of the oil under examination, and again shaking vigorously for about 1 min. A 5% solution of sesame oil in olive oil gave a purple alcoholic layer on allowing to stand for 5 mins.; unadulterated samples gave a light red or greenish colour.

—F. W. A.

Soap solutions. III. V. Lenher and G. M. Bishop. *J. Phys. Chem.*, 1918, **22**, 95—98.

COMPARATIVE experiments in which *N*/10 sodium oleate solution was filtered through layers of animal charcoal, willow charcoal, and Ceylon graphite respectively show that the adsorption of the soap by the three forms of carbon diminishes in the order in which these are written. (See also *J. Chem. Soc.*, May, 1918.)—H. M. D.

Glycerol; Estimation of — by Wagenaar's method. J. H. M. Beckers and I. M. Kolthoff. *Pharm. Weekblad.* 1918, **55**, 272—281.

WAGENAAR'S method of estimating glycerol gives results dependent on the composition and temperature of the liquid. Methyl alcohol is without influence on the reaction, but the presence of ethyl alcohol, halides, nitrates, and to a less degree sulphates, is deleterious. With fats, it is best to saponify with methyl-alcoholic potash, and liberate the fatty acids with the minimum quantity of sulphuric acid.—A. J. W.

Glycerin; Estimation of the amount of water in —. I. M. Kolthoff. *Pharm. Weekblad*, 1918, **55**, 301—307.

AN account of a method of estimating the percentage of water in glycerin by observing the temperature range of complete miscibility of mixtures of the sample and aniline. A table showing the corresponding percentages of water is given.

—A. J. W.

Fats and fatty acids from petroleum. Moore and Egloff. See IIA.

PATENTS.

[*Hydrogenation of oils*:] *Process of making metallic catalysts* [for —]. W. D. Richardson. Chicago, Ill. U.S. Pat. 1,257,396, Feb. 26, 1918. Date of appl., Nov. 11, 1912.

A PERMANENT catalyst, consisting of an electrically disintegrated colloidal metal in a fluid fatty mass, is obtained by producing an electric arc between two metallic, *e.g.*, nickel, electrodes submerged in a liquid or semi-liquid fatty substance, until from 1 to 20% of the metal has been disintegrated, stirring being maintained the while to diffuse the disintegrated metal throughout the mass.

—A. DE W.

Hydrogenating oils or fats: *Process of —.* W. D. Richardson, Assignor to Swift and Co., Chicago, Ill. U.S. Pat. 1,257,397, Feb. 26, 1918. Date of appl., Nov. 11, 1912.

A METAL is electrically disintegrated in a fluid medium, *e.g.*, water, the fluid medium removed,

and the disintegrated metal added to the oily or fatty material, which is then treated with hydrogen.

—A. DE W.

[*Hydrogenation of oils*:] *Process for making catalysts* [for —]. W. D. Richardson, Assignor to Swift and Co., Chicago, Ill. U.S. Pat. 1,257,531, Feb. 26, 1918. Date of appl., May 6, 1915.

A COLLOIDAL metallic catalytic material is obtained by electrically disintegrating thick electrodes comprising nickel in a liquid medium, *e.g.*, water, the finely-divided precipitate containing nickel being collected, freed from liquid medium, and then mixed with oil.—A. DE W.

Method and apparatus for removing oils, fats, and greases from cloths. U.S. Pat. 1,256,356. See V.

Process for making drying oils from mineral oils. U.S. Pat. 1,256,355. See XIII.

Process of making drying oils. U.S. Pat. 1,256,356. See XIII.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

PATENTS.

Titanium compounds; Manufacture of pigments from —. Det Norske Aktieselskab for Elektrokemisk Industri, Christiania, Norway. Eng. Pat. 104,885, Mar. 15, 1917. (Appl. No. 3815 of 1917.) Under Ind. Conv., Mar. 8, 1916.

TITANIUM hydrates (metatitanic or orthotitanic acid) containing undesirable impurities of an acid character, *e.g.*, basic titanium sulphate, are washed with water until neutral and then treated in the moist condition with a soluble compound of a metal, *e.g.*, barium chloride, forming a neutral insoluble sulphate not injurious to the titanic acid as a pigment, in an amount necessary to combine with the sulphuric acid of such basic sulphate. The impurity may also be removed by first treating the impure titanic acid with a base such as soda in quantity insufficient to neutralise all the sulphuric acid of the basic titanic sulphate present, removing the soluble sulphate formed, and converting the residual sulphuric acid into insoluble sulphate as above, or by using excess of base and subsequently removing the excess with acid.—A. DE W.

Lamp black; Manufacture of —. J. J. Shedlock, Little Bentley, Essex. Eng. Pat. 114,040, Mar. 21, 1917. (Appl. No. 4127 of 1917.)

A VEGETABLE or mineral fat or oil is heated and then discharged through a perforated pipe on to the heated bed-plate of a chamber, where the vapour is brought into immediate contact with jets of heated air, the flow of oil or fat and heated air being so regulated that on ignition of the vapours the hydrogen constituent only of the oil or fat is oxidised. Means are provided for withdrawing the liberated carbon constituent and collecting it by subjecting it to the action of sprays of any suitable liquid wherein it is absorbed, *e.g.*, of hydrocarbon oils or tar, when required to be adapted for the manufacture of carbon rods or plates, or of water, when required for use as a pigment, etc.—A. DE W.

Zinc-lead pigment [; *Process and apparatus for making* —]. J. A. Singmaster and F. G. Breyer, Palmerton, Pa., Assignors to New Jersey Zinc Co., New York. U.S. Pat. 1,257,136, Feb. 19, 1918. Date of appl., Oct. 26, 1917.

A ZINC-LEAD pigment containing 65%—97% of zinc oxide and possessing a covering power, opacity, flow, and whiteness equal to that of "XX brand of American process zinc oxide" is obtained by volatilising at a high temperature the zinc and lead from an oxidised ore and subjecting the same to a regulated sulphating and oxidising atmosphere, so that the lead is converted into sulphate to the required degree without materially sulphating the zinc or unduly maintaining the furnace at an elevated temperature.—A. DE W.

Drying oils from mineral oils; Process of making —. W. Dyer, Portland, Oreg. U.S. Pat. 1,256,535, Feb. 19, 1918. Date of appl., Nov. 7, 1916.

A MIXTURE of 10—20 parts of non-drying mineral oil, which has been freed from gasoline and kerosene, and one part of alcohol is boiled for a sufficient length of time to convert the mineral oil into a drying oil.—A. DE W.

Drying oils; Process of making —. W. and W. E. Dyer, Portland, Oreg. U.S. Pat. 1,256,536, Feb. 19, 1918. Date of appl., Apr. 12, 1917.

A "NON-DRYING" or "semi-drying" fatty oil is mixed with a relatively smaller bulk of alcohol, and the mixture boiled until an oil of good drying properties is obtained.—A. DE W.

Paint; Thinned — and *process of making paint-thinner* [from mineral oils]. W. and W. E. Dyer, Portland, Oreg. U.S. Pat. 1,256,537, Feb. 19, 1918. Date of appl., June 7, 1917.

A PAINT thinner is obtained by boiling a mixture of about 9—19 vols. of mineral oil having a gravity about that of kerosene, and one vol. of alcohol for about half an hour. The thinner is claimed to have "drying properties," to be capable of hastening the drying of paints containing drying oils, and to possess a heavier "body" than kerosene, gasoline, or turpentine.—A. DE W.

Varnish; Manufacture of —. R. Weeber, Bärn, Austria. U.S. Pat. 1,257,562, Feb. 26, 1918. Date of appl., Feb. 19, 1914.

A SEMI-DRYING oil, such as train oil, is treated in a comparatively cold state with a lye to saponify the free fatty acids, the soap thus formed removed, and the oil then polymerised to a varnish with the aid of siccatives.—A. DE W.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Vulcanisation without sulphur by Ostromyslenski's method. E. Bunschöten. Chem. Weekblad, 1918, 15, 257—268.

AN investigation of the mechanical properties of the products obtained by Ostromyslenski's method (this J., 1916, 59). The use of raw rubber and nitrobenzene or *m*-dinitrobenzene, with or without *p*-nitrosodimethylaniline or acetaldehyde-ammonia as catalyst, gives unsatisfactory results, as stated by Stevens (this J., 1917, 107). The process is much assisted by addition of lead oxide, and tables are given showing the influence of time, temperature, and proportion of materials on the mechanical properties of the products, as determined by means of Schopper's dynamometer.

—A. J. W.

PATENTS.

Rubber; Process of reclaiming —. H. R. Murdock, Naugatuck, Conn., Assignor to Rubber Regenerating Co. U.S. Pat. 1,257,292, Feb. 19, 1918. Date of appl., Oct. 8, 1915.

THE fibrous material in waste rubber is destroyed by treatment with carbohydrates other than cellulose, *e.g.*, starch, the products of hydrolysis of which, under the conditions of devulcanisation, effect its decomposition into a brittle substance.
E. W. L.

Rubber compound and method of producing the same. F. J. Gleason, Walpole, Mass., Assignor to Standard Woven Fabric Co., Framingham, Mass. U.S. Pat. 1,275,698, Feb. 26, 1918. Date of appl., Nov. 20, 1915.

COTTON and ground, vulcanised rubber are milled together until they have become thoroughly mixed, and the cotton is in a hard, flaky condition; the mixture is then ground, until the rubber is pulverised and the cotton is in a finely divided and fluffy condition, and used as an ingredient of a rubber mixing.—E. W. L.

Rubber and the like; Machinery for [kneading] —. S. C. Davidson, Belfast. U.S. Pat. 1,256,664, Feb. 19, 1918. Date of appl., June 7, 1915.

Waterproof material for use in constructional purposes, as a substitute for leather, for street paving and the like. Eng. Pat. 111,485. See IX.

XVI.—SOILS; FERTILISERS.

Soils; Water extractions of — as *criteria of their crop-producing power*. J. S. Burd. J. Agric. Res., 1918, 12, 297—309.

THE author has determined the amounts of water-soluble nitrate, phosphate, and basic ions (potassium, calcium, magnesium) in good, medium, and poor soils, in the cropped and the uncropped state, and also the amounts of these constituents in a crop of barley produced on these soils. The results indicate that there is always present in soils, in a condition permitting ready solution in water, enough of the more important chemical elements to supply the immediate needs of the crop. This supply never entirely disappears in soils which are at all productive, but it would appear that a plant may be unable to satisfy its requirements if the concen-

tration with reference to the individual ions falls below certain minima. Further the optimum concentration probably varies with the soil according to the physico-chemical system present in the soil solution. There are certain characters which indicate the composition of the soil and its productivity, but these involve three variables and it is not possible to give an exact correlation between productivity and the concentrations of these three variables. To obtain a precise measure of soil fertility the soil must be studied concurrently in the cropped and the uncropped condition and under strict control.—W. G.

Soil extract; Effect of season and crop growth in modifying the —. G. R. Stewart. J. Agric. Res., 1918, 12, 311—368.

THIRTEEN soils, belonging to two different types, silty clay loams and fine sandy clay loams, were used and the water-soluble nutrients in them were periodically determined during two seasons. In the first season all the soils were cropped with barley, but in the second season comparisons were made between cropped and uncropped duplicates. Marked differences were observed between the contents of nitrates, calcium, magnesium, and potassium present in the water extracts from the cropped and uncropped soils, but similar differences were not shown by phosphates. The phosphate content of different soils varied considerably, but for a given soil it was practically constant in both the cropped and the uncropped plot. During the growing season the concentrations of nutrients in eight of the thirteen cropped soils were practically the same, although striking differences were obtained in the uncropped soils. The three poorest soils yielded the smallest amounts of water-soluble nutrients and the smallest differences between the cropped and uncropped duplicates. The results of the investigation indicate that large amounts of water-soluble nutrients are developed by cultivation, fallowing, and biennial cropping. —W. G.

Soil solution; The freezing-point method as an index of variations in the — due to season and crop growth. D. R. Hoagland. J. Agric. Res., 1918, 12, 369—395.

THE results obtained by the freezing-point method of Bouroucos and McCool (Mich. Agr. Exp. Stat. Tech. Bull. No. 24, 1916) on the soils used by Stewart (see preceding abstract) confirm his results obtained by the extraction method as to the variation in the concentration of the soil solution. This concentration may vary greatly for the same soil under different conditions, such as season, leaching, incubation, or treatment with carbon dioxide. The growth of a crop markedly diminishes the concentration of the soil solution, this effect being still evident eight months after the crop has been removed. The results indicate that the soil solutions should not be considered as saturated, and under conditions favourable to crop growth they were found to be very dilute, particularly at the height of the growing season. —W. G.

Carbonic acid gas in relation to soil acidity changes. H. A. Noyes and L. Yoder. Soil Sci., 1918, 5, 151—161.

SOIL kept at one-half its water-holding capacity in a greenhouse, either with or without a crop, increased its acidity. The increase in acidity of cropped soil was modified by applications of calcium carbonate, and varied with different fertiliser applications. Carbon dioxide passed through a cropped soil, treated with lime alone or lime plus fertiliser, increased the acidity of the soil.

The experimental results indicate that soil acidity is largely the result of hydrolytic mass action phenomena.—W. G.

Bacteria of certain Wisconsin soils; Influence of carbonates of magnesium and calcium on —. H. L. Fulmer. J. Agric. Res., 1918, 12, 463—504.

THE three soils used were an acid and a neutral silt loam and an acid sand. In all cases the application of calcium or magnesium carbonate caused an increase in the number of bacteria in the soil, whether sterilised or unsterilised, a greater increase being obtained in the acid soils than in the neutral soil. Magnesium carbonate was more effective than calcium carbonate in this respect. Ammonification and nitrification were both benefited by the application of these carbonates, but the increase in ammonifying power was not always parallel with the increase in the total number of bacteria in the soil. The data as a whole indicate that magnesium carbonate is superior to calcium carbonate in stimulating the reproduction of bacteria in these three soils, and that, in general, smaller applications of either carbonate give better results than do the heavier applications.—W. G.

Ammonium phosphate; Some availability studies with — and its chemical and biological effects upon the soil. F. E. Allison. Soil Sci., 1918, 5, 1—80.

THE commercial ammonium phosphate used was manufactured by the American Cyanamid Company by the following process. Ground rock phosphate was mixed with sufficient sulphuric acid to liberate the whole of the phosphoric acid, which was filtered off. Ammonia, generated by the action of steam on calcium cyanamide under pressure, was bubbled through the phosphoric acid solution until di-ammonium phosphate was formed. Sufficient phosphoric acid was added to convert this into the mono-ammonium salt, and the solution was evaporated to dryness, giving commercial "Ammo-Phos." This material contained 13.5% NH_3 and 43% P_2O_5 , of which 96.5% was either water- or citrate-soluble. This was compared as a nitrogenous fertiliser with ammonium sulphate, dried blood, and cottonseed meal, and the average nitrogen recovery for six crops on Norfolk sand, ammonium phosphate coming first, was respectively 65.88, 61.10, 43.74, and 41.19%, and on a Sasafra loam 48.46, 50.42, 42.51, 36.49%. The crop yields were about in the same ratio as the nitrogen recoveries, except that under very acid conditions ammonium sulphate frequently showed a higher recovery of nitrogen but a much smaller crop than ammonium phosphate. Ammonium phosphate produced a smaller increase in soil acidity than did ammonium sulphate. There was very little difference in the availability of the phosphorus in ammonium phosphate, acid phosphate (superphosphate), or basic slag. Ammonium phosphate showed about the same toxicity to germination and early growth as ammonium sulphate and less than sodium nitrate or ammonium chloride when applied to soils in high concentrations. Of the crops examined, corn (maize), buckwheat, barley, wheat, and oats were resistant to large applications of fertilisers, while vetches, rape, and cowpeas were relatively susceptible. As a fertiliser ammonium phosphate is in general of the same value as an equivalent amount of nitrogen as ammonium sulphate and phosphorus as superphosphate. (See also J. Chem. Soc., May, 1918).—W. G.

Ammonium sulphate; Significance of the sulphur in — applied to certain soils. C. B. Lipman and W. F. Gericke. Soil Sci., 1918, 5, 81—86.

THE addition of sulphur, in the form of sulphuric

acid or sodium sulphate and to a lesser extent in the form of flowers of sulphur, to sodium or calcium nitrate or dried blood resulted in these fertilisers giving nearly as good a crop of barley grown on Oakley blow sand in pots, as did ammonium sulphate alone. The sulphur compounds applied without the nitrogenous fertiliser gave no increase over the control pots. (See also J. Chem. Soc., May, 1918.)—W. G.

Ammonium sulphate: Effect of — in nutrient solution on the growth of soya beans in sand cultures M. I. Wolkoff. Soil Sci., 1918, 5, 123—150.

AMMONIUM sulphate, when substituted for potassium nitrate in Tottingham's series of nutrient solutions (mixtures of KH_2PO_4 , KNO_3 , $\text{Ca}(\text{NO}_3)_2$, and MgSO_4) in sand cultures, gave a better yield of soya beans in certain salt proportions than in the corresponding salt proportions with potassium nitrate, but caused considerable injury when added in excess. The foliage of the plants in the ammonium sulphate series had a greener colour than in the other series. There is a very close relation between the yield of tops, yield of roots, and the total transpiration of the plants. The amount of water required to produce 1 gm. of dry matter of soya bean tops was less in the ammonium sulphate series than in the other series. —W. G.

Phosphates: Toxicity of monobasic — towards soybeans grown in soil and solution cultures J. W. Shive. Soil Sci., 1918, 5, 87—122.

THE monobasic phosphates examined were those of potassium, sodium, ammonium, magnesium, and calcium, and the plants were grown (a) in soil cultures to which the salts were added singly in solutions having osmotic concentration values varying from 0.5 to 7 atmos; (b) in soil cultures to which the phosphates were applied in conjunction with a complete fertiliser in solutions with varying salt proportions but with total osmotic concentration values of 2.5 atmos; (c) the mixed solutions employed in the preparation of the soil cultures were also used for water cultures without alteration. The results from series (a) show that, from the point of view of yield, the growth of soya bean tops was injuriously affected by each of the five phosphates, specific injury to the plants being identical in every case and caused when the solution applied had osmotic concentration values above 1 atmos. Arranged in order of increasing toxicity the phosphates are KH_2PO_4 , $(\text{NH}_4)_2\text{H}_2\text{PO}_4$, $\text{MgH}_2(\text{PO}_4)_2$, NaH_2PO_4 , $\text{CaH}_2(\text{PO}_4)_2$. The phosphates also caused pronounced injury when used in conjunction with a complete fertiliser, but not to a sufficient degree to kill the plants. In these cases the degree of injury was not determined solely by the total phosphate content of the medium but was also related to the relative proportions of the constituent salts. In the solution cultures the phosphates arranged in order of increasing toxicity are NaH_2PO_4 , $(\text{NH}_4)_2\text{H}_2\text{PO}_4$, KH_2PO_4 , $\text{MgH}_2(\text{PO}_4)_2$, $\text{CaH}_2(\text{PO}_4)_2$. The acid content of the solutions bears a definite relation to the specific injury sustained by the plants grown in them. The higher the acid content the greater is the degree of injury suffered by the plants. The relative salt proportions, however, play a very important rôle in either accentuating or diminishing the injury when the acidity of the solutions is sufficiently high to produce it.—W. G.

Potash in fertiliser materials: Study of the De Roode method for the determination of —. T. E. Keitt and H. E. Shiver. J. Ind. Eng. Chem., 1918, 10, 219—222.

In the Lindo-Gladding method (Chem. News, 1881,

44, 77, 86, 97, 129; U.S. Dept. Agric., Div. of Chem. Bull., 1885, 7, 38) the whole of the potash present in water soluble form is not accounted for and the tedious separation of the alkaline-earth bases is liable to be accompanied by occlusion of potash. The method of De Roode (this J., 1895, 599), as now modified, is much simpler and avoids the use of platinum evaporating dishes, while the degree of accuracy is eminently satisfactory. Ten grms. of the sample is placed in a 500 c.c. flask and boiled with 300 c.c. of water for 30 mins., then diluted to the mark. Fifty c.c. of the clear solution is evaporated to dryness in a porcelain dish with 3—5 c.c. of nitric acid to destroy organic matter and the residue is treated with hot water and excess of hydrochloric acid. The solution is again evaporated to dryness and the residue treated with hot water and several drops of hydrochloric acid, and sufficient platinum chloride is added to the solution to precipitate all the potash present. The precipitate is covered with acidulated alcohol and allowed to stand for 15—20 mins., in which time all the iron, aluminium, and magnesium will dissolve; the precipitate is filtered off, washed until the filtrate is colourless, then washed well with ammonium chloride solution saturated with potassium platinochloride; this washing should be thorough, since the accuracy of the result largely depends on it. Lastly the precipitate is washed with 95% alcohol to remove the ammonium chloride, dried, and weighed. The preparation of the acidulated alcohol is as follows:—to each 1000 c.c. of 95% alcohol, 75 c.c. of concentrated hydrochloric acid is added, then dry hydrogen chloride is passed into the mixture until 1 c.c. of the alcohol neutralises 2.25 c.c. of N/1 alkali, using phenolphthalein as indicator. Potassium platinochloride is soluble in this alcohol to the extent of about one part in 60,000 at the ordinary temperature. This quick and simple method has been thoroughly tested and is much more accurate than the Lindo-Gladding method.—J. F. B.

Water hyacinth (Eichornia crassipes): its value as a fertiliser. R. S. Finlow and K. McLean. Agric. Res. Inst. Pusa. Bull. No. 71, 1917, 16 pages.

THE whole fresh green plant of the water hyacinth contains on the average: moisture 95.5%, organic matter 3.5% (containing N 0.04%), ash 1.0%. The average composition of the ash is K_2O 28.7%, Na_2O 1.8%, CaO 12.8%, Cl 21.0%, P_2O_5 7.0%. The material if well-rotted has about the same composition as farmyard manure except that it is much richer in potash. If the fresh green plant is stacked immediately for rotting, a very serious loss of fertilising ingredients may take place in the liquid exuding from the heap. It is preferable, therefore, to dry the plant for several days before stacking it. Field tests have shown that water hyacinth either in the rotted state or as ash is a valuable manure on laterite soils of the old alluvium in Bengal.—W. G.

Germination: Influence of acids on —. L. Maquenne and E. Demoussy. Comptes rend., 1918, 166, 547—552.

MINERAL acids, as such, are amongst the substances most injurious to germination, but their action is modified by the addition of salts, or by the presence of the salts that the acid may form by its action on the teguments of the seeds or on the glass of the containing vessel (compare this J., 1917, 932; 1918, 132 A). Calcium appears to be one of the most powerful antitoxic substances in this respect. (See also J. Chem. Soc., May, 1918.)—W. G.

Alunite deposits of Australia and their utilisation. See VII.

PATENTS.

Soil; Method of and apparatus for the treatment of —. R. E. C. L. Guinness, London, and E. R. Richards, Harpenden. Eng. Pat. 113,860, Mar. 21, 1917. (Appl. No. 4123 of 1917.)

In a process for the heat treatment of soil to be cultivated, a predetermined thickness of the soil is thoroughly broken up and the fragments simultaneously heated to 80°–100° C. The apparatus consists of a self-propelled or other carriage provided with a flame or radiant heat producer, mechanism for rousing, agitating, stirring, or conveying the broken soil, and a motor and speed-changing device for actuating this mechanism—for example, a ploughshare mounted to deliver the soil to a rotary cutter, and thence to an agitating chamber (a rotating cylinder fitted with rakes) wherein the heating is effected.

W. E. F. P.

Phosphatic manure; Manufacture of a —. S. Crook and F. W. Gilbertson, Pontardawe, Glam. Eng. Pat. 113,618, Feb. 26, 1917. (Appl. No. 2819 of 1917.)

A MIXTURE of finely divided mineral phosphate with one or more alkali bisulphates, preferably nitre-cake, is made into a stiff, non-setting paste with water, then dried and ground for use.

W. E. F. P.

Fertilising material; Process for preparing —. T. A. Dungan, Chicago, Ill. U.S. Pat. 1,257,591, Feb. 26, 1918. Date of appl., Apr. 3, 1917.

STERILISED organic material is inoculated with aerobic bacteria, which are permitted to develop while air is forced continuously through the mass.—J. F. B.

XVII.—SUGARS; STARCHES; GUMS.

Sugar factories; Theory and practice in the design of multiple evaporators for —. A. L. Webre. J. Ind. Eng. Chem., 1918, 10, 191–198.

CERTAIN points in the engineering design of the evaporators are discussed. The coefficient of heat transmission from the steam to the heating surface varies with the temperature; this is illustrated by a curve. The presence of non-condensable gases in the steam has a marked retarding effect, particularly if sufficient means are not adopted for ensuring complete agitation of the steam; moreover, under reduced pressure, any gases leaking in occupy a larger volume. Means should be provided for the proper venting of the steam belts into a large header connected to the vapour space of the last effect; accumulations of condensed water in this header must be prevented. In regard to heat transmission considered from the liquor side, the circulation of the liquor from the top of the steam drum to the bottom, as distinguished from vigorous agitation due to the escape of vapours up the tubes, has no beneficial effect. There is a hydrostatic increase of pressure due to the column of liquid, which raises the boiling point in the lower part of the apparatus, and it is detrimental to work at a higher level than is necessitated by the conditions prevailing. The accumulation of scale in the tubes is most detrimental; frequent periodical cleaning by boiling out, first with caustic soda and then with dilute hydrochloric acid, and if necessary by mechanical scrapers, is the rule. Rapid circulation impedes the incrustation of mechanically suspended matter but not of chemical deposits. The total drop of temperature between that of steam at 5 lb. pressure to vapour under 26 ins. vacuum is not equally divided between the four effects, but increases

towards the later ones. Various factors determine this rule. The coefficient of heat transmission falls from one effect to the next; the boiling point, compared with that of water under the same pressure, rises as the liquor becomes more concentrated; the effect of the hydrostatic head of liquid increases with the increase of density in the successive effects, so that the pressure indicated by the vacuum gauge for the vapour at the surface of the liquid does not represent the average pressure through the length of the tube; the increase in viscosity of the liquor also diminishes the available temperature-drop, according to imperfectly defined laws, to an extent approximately equal to that due to rise of boiling point. Combining the temperature losses due to boiling point, static head, and viscosity with the normal working drop determined by the available coefficient of heat transmission, the total temperature difference of 102° F. (57° C.) is divided between the four stages in the proportions of 15°, 18°, 23°, and 46° F. (8°, 10°, 13°, and 26° C.) respectively. A table is given showing the destination and amount of heat entering and leaving each stage and the amount of water evaporated for a given set of conditions. From this table the distribution of heating surface, at an average evaporation of 5½ lb. per sq. ft. per hour, is calculated, and it is found that in standard practice the second, third, and fourth vessels may be equally dimensioned, according to their mean requirements, and the first may be given double the heating surface of the others. The steam pipes, exhaust pipes, and vapour pipes should be dimensioned for a velocity of 100 ft. per sec., except in the case of the last effect, where, on account of the low density of the steam, 200 ft. per sec. is permissible. Loss by frothing is very rare; the best means for preventing it is to maintain a high vacuum; grease or oil is sometimes used. Loss by spraying is often serious; the mean height of projection of particles of liquid can be calculated from the volume and velocity of the vapour generated. Thus it is found that spraying may be very serious in the fourth vessel and perhaps also in the third. Sudden generation of vapour up the tubes should be avoided by distributing the admission of liquor over a wide area by a perforated coil or other device. Baffle-plates arranged in the vapour space above the liquor are also advantageous.

—J. F. B.

Ash of cane and beet sugar products; Determination of the —. J. P. Ogilvie and J. H. Lindfield. Intern. Sugar J., 1918, 20, 114–117.

SCHWEIZER (Archief Suikerind. Ned.-Indie, 1916, 24, 214–216) observed that the customary deduction of 10% for the conversion of the sulphated to the carbonated or so-called "true ash" is far from correct in the case of Java molasses. The authors corroborate this and give the results of determinations made with a number of cane and beet sugars and molasses from different countries. The sulphated ash was found in the usual manner, using 6 grms. of the sample and 1.5 c.c. of concentrated sulphuric acid; while the carbonated ash was ascertained by the method of carbonising below red heat, dissolving out the alkali salts, and incinerating the carbonised mass, the ash obtained and the residue from the evaporation of the solution of the alkali salts being heated to a low temperature after the addition of a little ammonium carbonate. Considerable differences in the correction necessary for converting the sulphated ash to the carbonated ash were found, even in products of the same class. In the case of beet sugars it varied from 12 to 25 but was never as low as 10%; in that of beet molasses from 12 to 18; and in that of cane molasses from 14 to 21; but with cane sugars the values were very irregular, fluctuating

between 6 and 26%. Varying factors are to be expected with cane sugars, owing to the presence in them of greater or less amounts of insoluble inorganic matter, which is partly sand, and partly salts thrown out of solution during evaporation and boiling and retained during curing in the centrifugals. Beet sugars, on the other hand, and beet and cane molasses contain a smaller and more constant quantity of insoluble ash. From the point of view of the refiner it is only the ash of the soluble matter that is of importance, and if this constituent were determined, in place of the total ash, a more exact indication of the value of refining sugars would be obtained. Determinations were made of the ash in sugars also by direct incineration followed by carbonating, as still practised by some chemists, but this procedure, owing evidently to the volatilisation of alkali salts, was found to yield appreciably lower results than either of the other two methods used.

—J. P. O.

Molasses; Notes on the analysis of —. H. S. Walker. *J. Ind. Eng. Chem.*, 1918, 10, 198—202.

DISCREPANCIES in the Clerget sucrose determinations in waste molasses have been investigated. It would appear that the method of clarification with basic lead acetate solution gives results which are too high by 0.5—0.7% of sucrose, on account of the large volume occupied by the lead precipitate. Clarification with dry basic lead acetate, after the solution has been made up to a measured volume, gives figures which are much closer to the true sucrose value but which are apt to be slightly low on account of dilution, especially if an excess of lead be used in clarifying. Artificial mixtures have been made up with known quantities of pure sucrose, invert sugar, and the product obtained from waste molasses after precipitating with lead, washing, and decomposing the lead precipitate by hydrogen sulphide. With these reconstructed molasses of known sucrose content, a method has been devised to avoid the error due to dilution in the dry basic lead acetate method. Twice the normal weight of molasses (52 grms.) is dissolved in water and made up to 300 c.c. The solution is clarified with 15—20 grms. of dry basic lead acetate and a few grms. of dry sand, and filtered. To 75 c.c. of the filtrate in a 100 c.c. flask, 20 c.c. of a solution containing 100 grms. of phosphoric acid per litre is added, and the mixture is made up to 100 c.c. If necessary, about 0.5 gm. of zinc dust may be added immediately before filtration to improve the colour. The direct polarisation is taken in a 400 mm. tube. Another portion of 75 c.c. of the original filtrate is treated with 2 c.c. of dilute hydrochloric acid (1 vol. of concentrated acid to 1 vol. of water) to neutralise the alkalinity, the liquid is heated to 65°—70° C., and 10 c.c. of the dilute hydrochloric acid is added. After 15 mins. the liquid is cooled, made up to 100 c.c., treated with zinc dust, and filtered. The divisor 1.421—0.51 is used for the Clerget formula. By this method the error due to the volume of the lead phosphate precipitate compensates for the error of dilution caused by any excess of lead originally dissolved. The amount of phosphoric acid prescribed is the largest which can be used without danger of inversion; its effect on the rotation of invert sugar is not quite equal to that of the hydrochloric acid in the Clerget solution, but the difference is negligible.

—J. F. B.

PATENTS.

Sugar; Process of refining —. R. R. Williams, Manila, Philippine Islands. U.S. Pat. 1,256,758, Feb. 19, 1918. Date of appl., Jan. 26, 1914. Renewed Aug. 29, 1917.

A SOLUTION of sugar is subjected to the electro-

lytic action of a direct current of electricity, whereby the impurities which are susceptible to electrolytic action are caused to pass through porous partitions into adjacent compartments, in which the electrodes are immersed in a stream of fresh water which carries the impurities away.—J. F. B.

Molasses; Recovery of sugar from —. F. Tiemann, Berlin. U.S. Pat. 1,256,952, Feb. 19, 1918. Date of appl., June 25, 1911.

SEE Ger. Pats. 279,719, 279,720, and 288,411; this J., 1915, 371; 1916, 375.

XVIII.—FERMENTATION INDUSTRIES.

Worts and beers; Physico-chemical investigations of —. W. Wöllner. *Z. ges. Brauw.*, 1917, 40, 387.

DETERMINATIONS of hydron concentration in worts of low specific gravity used for the preparation of war-beers, gave values much lower than those for worts of normal gravity correspondingly diluted with distilled water. In thin brewery worts the acid-reacting malt constituents are not only abnormally diluted but also largely neutralised owing to the relative preponderance of the salts of the brewing water. The low hydron concentration of thin worts must affect the transformation of hop-resins (cp. this J., 1918, 218 A) and the activity of the yeast. The deficiency is not made good during fermentation, for the hydron concentration of fermented war-beer was found to be abnormally low.—J. H. L.

Wort and beer; Bacteria [B. termo] in —. P. Petit. *Brasserie et Malterie*, 1917, 7, 273—277.

THE author describes the effects of infection of worts by the organisms known collectively as *Bacterium termo*. Such infection very commonly occurs, especially in hot weather, as the result of contact of the wort with infected utensils or germ-laden air. Although not usually considered very dangerous, since they are suppressed during fermentation and therefore not found in the finished beer, these organisms may give rise to defects more or less serious. The best known of these is the bad odour which they produce in worts and which may even persist in the beer; but if present in large numbers they may weaken the yeast and thus retard fermentation, and give rise to difficulties of filtration and clarification in beers predisposed to these defects. It is probable that many cases of infection and haze in beers are indirectly due to infection of the wort by *B. termo*, which although completely eliminated during fermentation, renders the beer abnormally subject to other disorders. Serious infection of wort with *B. termo* is most easily detected during the later stages of the primary fermentation, the organisms being then dead but still in suspension, sometimes in sufficient numbers to cause opalescence. Practical measures for tracing the infection to its source are discussed.—J. H. L.

PATENTS.

Yeast; Process for pressing — and apparatus for use therein. E. A. Meyer, Bristol. Eng. Pat. 113,628. (Appl. Nos. 17,338, Dec. 2, 1916, and 8804, June 19, 1917.)

THE yeast is deposited on the surface of a drum revolving in a tank containing the liquid suspension of yeast; the air is exhausted from the drum and a knife is adjusted so that it skims off only the dry outer layer of the deposited yeast, leaving the lower moist layer on the drum to prevent the breaking of the vacuum. This effect is also assisted by providing, below the knife and in close

proximity to it, a perforated pipe through which a liquid containing yeast is constantly sprayed over the surface of the drum.—J. F. B.

Minim-alcoholic beverages: Method of preparing —. E. Gudeman, Chicago, Ill. U.S. Pat. 1,256,894, Feb. 19, 1918. Date of appl., June 22, 1908.

THE beer charge is subjected in an open vessel to the action of free steam in copious and regulated quantity to agitate the charge and heat it to somewhat below the boiling point, the supply of steam being such that the major portion of it is forced through the charge to drive off the alcohol, while a small portion condenses to maintain the volume of the charge practically constant.—J. F. B.

Extract having the flavour and aroma of malt, process of producing same, and beverage therefrom. M. and L. Wallerstein, New York. Eng. Pat. 107,367, Jan. 17, 1917. (Appl. No. 882 of 1917.) Under Int. Conv., June 21, 1916.

SEE U.S. Pats. 1,214,729 and 1,214,730 of 1917; this J., 1917, 400.

XIXA.—FOODS.

PATENTS.

Food products [potatoes]: Method of preparing pre-cooked —. Condensed Food Co., Philadelphia, Pa., U.S.A. Eng. Pat. 113,900, June 28, 1917. (Appl. No. 9196 of 1917.) Under Int. Conv., Apr. 21, 1917.

PEELED potatoes are cooked for 20 to 40 minutes by steam at 220° to 230° F. (104° to 110° C.) and about 15 lb. pressure, then cut into thin shreds ("riced"), which are dried while still hot in a current of air at about 180° F. (82° C.). This drying operation requires from 25 mins. to 2 hours. The product keeps indefinitely in cardboard packages. The process may also be applied to sweet potatoes, carrots, and other vegetables.—W. P. S.

Food; Means for preserving —. L. L. Kahn, San Francisco, Cal. U.S. Pat. 1,256,495, Feb. 12, 1918. Date of appl., Aug. 18, 1917.

A TIN for containing preserved foods is provided with a celluloid lining which completely encloses the food and prevents the latter from coming into contact with the metal.—W. P. S.

Drying apparatus [for fruit]. G. D. Parker, Riverside, Cal. U.S. Pat. 1,256,825, Feb. 19, 1918. Date of appl., June 27, 1917.

THE dryer comprises a housing open at the bottom, through which air is forced in a downward direction. Inside the housing is a series of superposed horizontal endless conveyors. The fruit is introduced at the top and is carried by the conveyors from one end of the housing to the other alternately in opposite directions in successively lower horizontal planes.—J. H. P.

XIXB.—WATER PURIFICATION; SANITATION.

PATENTS.

Suspended matter: Means for maintaining — in liquids in a state of suspension without precipitation [e.g., in water softening]. A. Pendlebury, Bradford. Eng. Pat. 114,016, Mar. 13, 1917. (Appl. No. 3645 of 1917.)

AN insoluble substance, such as lime, is mixed with water to a required density by means of

agitators in two mixing tanks placed side by side on the ground level. To the tanks is fitted a common suction pipe with a valve to each tank, so that one tank can be filled whilst the other is being emptied. This pipe is connected to a centrifugal pump capable of delivering about double the quantity of liquid required. The liquid is delivered into a tank at a higher level from which measured quantities are taken for addition to the water or other liquid to be treated. The upper tank has a semi-circular bottom and the pressure of the pump keeps the mixture in motion and prevents any settling. Surplus liquid overflows and falls back into the mixing tanks.—J. H. P.

Filter-body [for removing germs from liquids]. G. H. Seitz and F. Schmitthenner, Assignors to Seitz-Werke T. und G. Seitz, Kreuznach, Germany. U.S. Pat. 1,256,171, Feb. 12, 1918. Date of appl., Mar. 10, 1917.

A PASTE consisting of infusorial earth, flax, cotton, and water containing formaldehyde is dried, formed into a suitable shape, and sterilised.—W. P. S.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Storax; Examination of —. L. van Itallie and H. J. Lemkes. Pharm. Weekblad, 1918, 55, 142—149.

THE determination of the cinnamic acid content is preferred to the acid or saponification values; the acid occurs in storax in the free state and as the cinnamyl, phenylpropyl, ethyl, and ricinoleic esters. The results of the examination of nine samples of storax are given. The free cinnamic acid cannot be determined from the acid value, which includes acids insoluble in water; moreover, if hydrolysis occurs, a high acid value results. Titration of the aqueous extract with alkali gives a much lower content of cinnamic acid than the following bromine method, which is recommended by the authors. 1 gram. of the sample is boiled with 20 c.c. of N/2 alcoholic potassium hydroxide for 1 hour under a reflux condenser, the mixture distilled on a water-bath, and the residue dissolved in 25 c.c. of water. The solution is extracted with 20 c.c. of ether, and the aqueous layer, together with two 5 c.c. portions of water used for washing the ether layer, diluted to about 950 c.c., treated with 10 c.c. of dilute sulphuric acid, made up to 1000 c.c., and filtered. 100 c.c. of the filtrate is treated with 10 c.c. of N/10 potassium bromate, 1 gram. of potassium bromide, and 5 c.c. of sulphuric acid; after 15 mins., 1 gram. of potassium iodide is added, and then, after a further 5 mins., the liberated iodine is titrated with thio-sulphate; 1 c.c. of N/10 KBrO₃ is equivalent to 7.4 mgrms. of cinnamic acid.—F. W. A.

Boron [e.g., in steel and minerals]; Spectroscopic detection of —. A. de Gramont. *Comptes rend.*, 1918, 166, 477—480.

USING the condensed spark, boron may be readily detected in steels, when present in small amounts, by the ray λ 3451.2 and the doublet λ 2497.82 and 2496.87. The same method may be employed for its detection in minerals after previous fusion with alkali carbonates. (See also *J. Chem. Soc.*, May, 1918.)—W. G.

Calorimeter design; Thermal leakage and —. W. P. White. *J. Amer. Chem. Soc.*, 1918, 40, 379—393.

THE influence of the air space round the calorimeter on the thermal leakage is considered with particular reference to the width of the air gap, the size of the calorimeter, and the use of adiabatic methods. The rate of heat interchange is approximately proportional to the difference of temperature between the calorimeter and its environment, except in so far as such interchange is caused by evaporation or convection. For ordinary calorimetric conditions the effect of convection is more nearly proportional to the square of the temperature difference. The convection effect diminishes rapidly as the width of the surrounding air gap decreases, and this reduction can be advantageously carried so far that the total thermal leakage is mainly due to conduction, which increases approximately in inverse proportion to the width of the air space. Calculation shows that gaps of 10 to 17 mm. are most suitable for ordinary calorimeters. In the case of larger calorimeters, the width of the air space may be increased beyond these limits without detriment to the influence of convection on the thermal leakage. Conduction may be reduced by the use of very thin reflecting shields, the use of which does not increase the convection effect. Evaporation must be reduced as far as possible by suitable design of the calorimeter, and attention must be given to thermometer lag in correcting the actual readings. (See also *J. Chem. Soc.*, May, 1918.)—H. M. D.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Anderson. Process of obtaining oil from tar or pitch. 7026. Apr. 26.
 Archer. Tar stills. 6667. Apr. 19.
 Harger and Helps. Manufacture of liquid fuel from dehydrated tar. 6752. Apr. 22.
 Klein. Dehydration of tar. 7032. Apr. 26.
 Wilton. Treatment of tar for improving its value for fuel purposes and for separation of products. 6375. Apr. 15.

COMPLETE SPECIFICATION ACCEPTED.

3609 (1917). Ransford (Cassella und Co.). Manufacture of chlorinated products of xylene and new compounds and dyestuffs therefrom. (114,645.) Apr. 24.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

Morton, Thomson, and Morton Sundom Fabrics, Ltd. Manufacture of anthracene derivative colouring matters. 6916 and 6917. Apr. 24.

Morton, Dandridge, and Morton Sundom Fabrics, Ltd. Production of colouring matters. 7009. Apr. 25.

COMPLETE SPECIFICATION ACCEPTED.

3609 (1917). Ransford (Cassella und Co.). *See* III

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Borzykowshi. Production of articles from viscose. 6346. Apr. 15. (U.S., May 29, 1917.)
 Gallon and Johnston. Pulp-making. 6528. Apr. 17.
 Orrell. Manufacture of paper, etc. 6473. Apr. 17.
 Robbins. 7111. *See* XII.
 Sutherland and others. 6909. *See* XIII.
 Ziman. Treatment of kapok fibre to render it antiseptic and fireproof. 6969. Apr. 25.

COMPLETE SPECIFICATION ACCEPTED.

9666 (1917). Heberlein und Co. Process for imparting new properties to cotton fabrics. (108,671.) Apr. 24.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATION.

Lord and Lord. Machines for dyeing, washing, scouring, sizing, bleaching, and mercerising yarn in hank form. 7109. Apr. 27.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATION.

Ascroft. Manufacture of nitrogen with or without other constituents. 6382. Apr. 15.
 Ascroft. Manufacture of nitrogen and its compounds, removal of oxygen from mixtures of gases, and obtaining useful products by oxidation and deoxidation. 6383. Apr. 15.
 Ascroft. Manufacture of oxides or salts of tungsten or of metallic tungsten. 6456. Apr. 17.
 Ascroft. Manufacture of oxides or salts of metals, or of metals, or of non-metals, from ores, minerals, residues, etc. 6457. Apr. 17.
 Ascroft. Manufacture of aluminium or its oxides or salts. 6548. Apr. 17.
 Ascroft. Manufacture of silicon chloride and removal of silica from fused melts. 6459. Apr. 17.
 Ascroft. Heat treatment of potash rocks with salts for extraction of potash. 6669. Apr. 19.
 Crosland. 6874. *See* IX.
 Fisher Chemical Engineering Co., and others. 6597. *See* XII.
 Langwell, and Power-Gas Corporation. Manufacture of salts of fatty acids, particularly acetates. 6778. Apr. 22.
 Norsk Hydro-Elektrisk Kvaestofaktieselskab. Manufacture of nitric acid. 6769. Apr. 22. (Norway, May 8, 1917.)
 Pease. Manufacture of alkaline cyanide and of ammonia therefrom. 6450. Apr. 16.
 Ridoni, and Soc. Talco e Grafitti Val Chisone. Manufacture of hydrofluoric acid. 6525. Apr. 17. (Ital., Apr. 19, 1917.)
 Ridoni, and Soc. Talco e Grafitti Val Chisone. Purification of natural graphites. 6837. Apr. 23. (Ital., May 5, 1917.)

COMPLETE SPECIFICATIONS ACCEPTED.

5096 (1917). Mellor. *See* II.
 5125 (1917). Maxted and Smith. Manufacture of nitrogen and of mixtures of nitrogen and hydrogen. (114,663.) Apr. 24.

5559 (1917). Armstrong. Powders for generating caustic alkalis. (114,896.) May 1.
 6596 (1917). Comment. Preparation of anhydrous zinc sulphide. (114,407.) Apr. 24.
 7737 (1917). Hayhurst. Condensers for acids. (114,706.) Apr. 24.
 8224 (1917). Gladysz. Manufacture of mixtures of sodium and potassium bitartrates. (107,020.) Apr. 24.
 9171 (1917). Kaltenbach. Sulphurous anhydride. (107,589.) Apr. 24.
 10,435 (1917). Ashcroft. Removal of soda from felspars or natural or artificial silicates or aluminates and manufacture of caustic potash. (114,743.) Apr. 24.
 11,535 (1917). Bloxam (Zellstoffabrik Waldhof). *See X.*
 13,721 (1917). Aktiebolaget Carlit. Manufacture of ammonium perchlorate. (110,544.) Apr. 24.
 13,883 (1917). Statham. *See XI.*

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Haddan (Corning Glass Works). Manufacture of glass for absorbing ultra-violet radiations. 6398 and 6399. Apr. 15.
 Hamblet. Admixtures for refractory clays. 6568. Apr. 18.
 Ionides. Pottery-burning, etc. 6663. Apr. 19.

COMPLETE SPECIFICATIONS ACCEPTED.

5441 (1917). Longstaff and Geairns. Manufacture of briquettes, silica, plastic, gainster, common fire, and like bricks. (114,676.) Apr. 24.
 13,963 (1917). Elektro-Osmose A.-G. Manufacture of ceramic and like ware. (113,777.) Apr. 24.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Crosland. Kiln or furnace for calcining limestone, cement, etc. 6874. Apr. 24.
 Ramsden. Acid-proof rock asphalte. 7101. Apr. 27.

COMPLETE SPECIFICATIONS ACCEPTED.

3317 (1917). Linden. Concrete or cement substances. (114,641.) Apr. 24.
 5420 (1917). Jolnerkevitch. Impregnation of wood, etc. (114,886.) May 1.
 5441 (1917). Longstaff and Geairns. *See VIII.*
 18,380 (1917). Deckers. Manufacture of cement from blast furnace slag. (114,794.) Apr. 24.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Ashcroft. Manufacture of chemically-reactive alloys. 6381 and 6967. Apr. 15 and 25.
 Ashcroft. 6546, 6547, and 6548. *See VII.*
 Brazil, Straker, and Co., and Shepherd. Electrodeposition of iron. 7074. Apr. 26.
 Crocker and Crocker. Increasing production of zinc dust from spelter retorts. 7025. Apr. 26.
 Elmore. Extraction of lead and zinc from their ores. 6668. Apr. 19.
 Harding. Conical mills for grinding ores, etc. 7059. Apr. 26.
 Industrial Inventions, Ltd., and Perry. Production of malleable iron castings. 7049. Apr. 26.
 Procter. Aluminium solder. 7128. Apr. 27.
 Prosser. Ore or metal concentrators. 6751. Apr. 22.

Quinan. Production of metals by reduction of oxides. 6832. Apr. 23.

Sumpter, and Vickers, Ltd. Surface-hardening steel plates, etc., and iron and malleable iron castings. 6537. Apr. 17.

Wade (Blaw-Knox Co.). Open-hearth furnaces, etc. 7000. Apr. 25.

COMPLETE SPECIFICATIONS ACCEPTED.

6093 (1917). Gaunt, Brookfield, and Tylor and Sons. Crucible and like furnaces. (111,684.) Apr. 24.
 11,464 (1917). Harbord. Furnaces for roasting ores. (114,953.) May 1.
 11,498 (1917). Jones. Production of spelter. (112,923.) Apr. 24.
 11,523 (1917). Metals Disintegrating Co. Process for reducing metals to a finely-divided state. (109,258.) Apr. 24.
 11,535 (1917). Bloxam (Zellstoffabrik Waldhof). Roasting pyrites, ores, etc., in shelf-burners. (114,954.) May 1.
 14,286 (1917). Lockwood. Electrodeposition of base metals. (114,976.) May 1.
 18,380 (1917). Deckers. *See IX.*

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Berry. Working of electric furnaces, and electrode used therein. 6678. Apr. 19.
 Bosch A.-G. Electrodes for spark discharges. 6459. Apr. 16. (Ger. Apr. 16, 1917.)
 Brazil, Straker, and Co., and Shepherd. 7074. *See X.*
 Etchells, Greaves, and Watson and Co. Electric furnaces. 6563. Apr. 18.
 Lawton. Electric furnaces. 6660 and 6661. Apr. 19.
 Leitner. Electric cells. 6432. Apr. 16.

COMPLETE SPECIFICATIONS ACCEPTED.

5412 (1916). Foley. Electric induction furnaces. (114,853.) May 1.
 13,883 (1917). Statham. Electrolytic cells especially for electrolysis of salt or similar material. (114,974.) May 1.
 14,286 (1917). Lockwood. *See X.*
 14,932 (1917). Dixon. Electric furnaces. (111,103.) Apr. 24.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Co-operative Wholesale Society, and Martin. Manufacture of cocoa butter. 6760. Apr. 22.
 Fisher Chemical Engineering Co., Hinchley, and Simon. Apparatus for extracting oils, wax, india-rubber, sulphur, etc., soluble in organic solvents. 6597. Apr. 18.

COMPLETE SPECIFICATIONS ACCEPTED.

5242 and 5243 (1917). Young. Apparatus and method for rapidly ageing soap. (114,878 and 111,879.) May 1.
 17,683 (1917). Johnson. Separation of fats, oils, or the like from liquids. (114,789.) Apr. 24.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Imray (Soc. Chem. Industry in Basle). Manufacture of weatherproof cement for paints. 7069. Apr. 26.
 Robbins. Preparation of dope for treating fabrics for aircraft. 7111. Apr. 27.
 Sutherland, and Wall Paper Manufacturers Ltd. Varnishes or dopes for fabrics of aeroplanes, etc. 6909. Apr. 24.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATIONS.

Banbury. Machine for treating rubber, etc. 6564. Apr. 18. (U.S., Apr. 20, 1917.)

Fisher Chemical Engineering Co., and others. 6597. *See* XII.

Gorell. Application of rubber coatings to articles. 6665. Apr. 19.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Marshall. Production of cake or powder glue from meat and/or slaughterhouse offal. 6800. Apr. 23.

Miller. Leather substitute for boots, etc. 6393. Apr. 15.

Wright. Tanning machinery. 6686. Apr. 20.

COMPLETE SPECIFICATION ACCEPTED.

1665 (1918). Vulcan Engineering Co., and Dickson. Machine for facilitating the handling and treatment of hides, skins, etc., in tanning and like operations. (115,009.) May 1.

XVI.—SOILS; FERTILISERS.

APPLICATIONS.

Marks (Soc. Anon. Ital. Ansaldo & Co.). Production of fertilisers. 6445. Apr. 16.

Marks (Soc. Anon. Ital. Ansaldo & Co.). Production of superphosphate minerals. 7058. Apr. 26.

COMPLETE SPECIFICATION ACCEPTED.

5062 (1917). Howorth (Norsk Hydro-Elektrisk Kvaestofaktieselskab. Manufacture of a phosphate fertiliser containing nitrogen. (114,873.) May 1.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATION.

Taikoo Sugar Refining Co. 6427. *See* II.

COMPLETE SPECIFICATION ACCEPTED.

7175 (1917). Hayashi, Emura, and Kwanto Sansho Kabushiki-Kaisha. Material for clarifying sugar solutions and means for regenerating the material after use. (108,303.) May 1.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATION.

Desborough and others. 6729. *See* XX.

COMPLETE SPECIFICATION ACCEPTED.

14,041 (1914). Barbet et Fils et Cie. Rectification of fermented musts, methyl alcohol, and other liquids. Apr. 24.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Co-operative Wholesale Society, and Martin. 6760. *See* XII.

Groff. Beverage. 6404. Apr. 16.

Graham. Bread, and process of producing same. 6971. Apr. 25.

Grousseau and Viconge. Treatment of cocoa and waste products of chocolate manufacture. 7094. Apr. 27. (Fr., June 11, 1917.)

Jones, and Jones and Attwood. Purification of sewage, etc. 7104. Apr. 27.

Kemp and Spencer. Dried eggs in powder form. 6502. Apr. 17.

COMPLETE SPECIFICATIONS ACCEPTED.

7275 (1917). Stamp. Apparatus for drying and deodorising nightsoil, slaughterhouse refuse, etc. (114,700.) Apr. 24.

7583 (1917). Giraud. Manufacture of aerated water. (108,852.) May 1.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Belart. Continuous process of manufacturing chloroform. 7106. Apr. 27.

Blanc. Manufacture of aromatic aldehydes. 7119. Apr. 27. (Fr., Apr. 27, 1917.)

Boake, Roberts, and Co., and Durrans. Production of alkylating agents. 6583. Apr. 18.

Boake, Roberts and Co., Durrans, and Perkin. Manufacture of ethylene. 7039. Apr. 26.

Boake, Roberts and Co., and Durrans. Manufacture of esters. 7040. Apr. 26.

Crosfield and Sons, and Hilditch. Manufacture of acetaldehyde. 6980. Apr. 25.

Desborough, Reilly, and Thaysen. Manufacture of lactic acid and its salts, etc. 6729. Apr. 20.

National Federation of Associated Paint, Colour, and Varnish Manufacturers of the United Kingdom, and others. Production of organic compounds, etc. 6734. Apr. 20.

COMPLETE SPECIFICATIONS ACCEPTED.

14,041 (1914). Barbet et Fils et Cie. *See* XVIII.

5669 (1917). Newton (Bayer und Co.). Manufacture of pharmaceutical products. (114,680.) Apr. 24.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

Agnew, Renwick, and Ilford, Ltd. High-temperature development of photographic materials. 6723. Apr. 20.

Eagle. Kinematograph films. 6959. Apr. 25.

Smith. Production of screens for half-tone and like photographic printing-surfaces. 6435. Apr. 16.

COMPLETE SPECIFICATIONS ACCEPTED.

4429 (1917). Wade. Kinematograph films. (114,871.) May 1.

7961 (1917). Crosland and Crosland. Preparation of sensitised paper or like flexible material for use in obtaining direct X-ray photographs or radiograms. (114,933.) May 1.

I.—GENERAL ; PLANT ; MACHINERY.

Evaporation and drying ; Some general aspects of — H. K. Moore, Amer. Inst. Chem. Eng., Dec. 7, 1917. Met. and Chem. Eng., 1918, 18, 128—133, 186—192.

DIRECT evaporation under atmospheric pressure or in a vacuum is used where: the amount of liquor to be evaporated is so small that it would not pay to have a multiple effect; the boiling points are very high; the liquor deposits an encrusting material on concentration; where crystals of a certain size are desired; the material to be evaporated is corrosive, or decomposes at a high temperature; the object is to recover a volatile constituent or to obtain artificially a low temperature or a sudden chill as in refrigeration processes; the liquor to be evaporated is already a concentrated solution and the product is separated as a dry film, powder, or mass of crystals. Direct vacuum evaporation (single effect) shows very little economy of steam over evaporation under atmospheric pressure and none at all if the vacuum has to be produced by steam power. Multiple-effect evaporation is used where the cost of fuel is high and the quantity of liquor to be evaporated is large. Air drying or gas drying depends upon the property of partially saturated air or gas of taking up more vapour, and it may be profitably employed in drying at a comparatively low temperature such materials as pulp, paper, cloth etc., which are continuously entering and leaving the apparatus; in drying at low temperatures substances of which the internal structure must be preserved; where the final product must be obtained in a fine state of division; in drying such substances as are not affected by heat but are sticky or poor conductors of heat. The heat necessary to evaporate the water may be supplied by the air or gas itself or may be applied directly. Drying by means of radiant heat is used when it is necessary to concentrate substances that require a high temperature and when there is no suitable material of which to construct ordinary apparatus. Mechanical drying by the use of filter and hydraulic presses, and centrifugal machines, and refrigerating machinery for drying gases are also briefly discussed. Several tables are given and the method of using them to solve evaporation and drying problems explained. The subject of heat conductivity is considered, and it is pointed out that the heat conductivity tables of physicists are of little use in practice, as the rate of heat exchange is largely increased when ebullition becomes violent owing to the rapid motion of the liquid. The phenomena in an evaporator tube, methods of calculating temperature differences, types of multiple-effect evaporators, and the relative advantages of forward and backward flow are discussed and illustrated by charts.—W. H. C.

PATENTS.

Distillation or evaporation of liquids [tar, petroleum, etc.] J. L. Major, Hull. Eng. Pat. 114,353, Apr. 26, 1917. (Appl. No. 5915 of 1917.)

THE liquid to be distilled is fed into an externally heated still through a number of pipes which extend from near the bottom of the still to the level of the surface of the liquid. The liquid in passing upwards through the pipes becomes heated and overflows from the upper ends of the pipes on to the surface of the main body of liquid in the still, the constituents of lower boiling point being vaporised before the liquid mixes with the main body. An annular tray with serrated edges

may be provided into which the pipes discharge and from the serrations of which the liquid overflows.—W. H. C.

Liquids and gases ; Apparatus for effecting intimate contact between — Kirkham, Hulett, and Chandler, Ltd., and S. Hersey, London. Eng. Pat. 114,370, June 16, 1917. (Appl. No. 8697 of 1917.)

IN apparatus for intimately mixing liquids and gases, of the type described in Eng. Pats. 18,129 of 1908, 23,813 of 1911, and 104,261 (this J., 1909, 873; 1912, 801, and 1917, 445), in which the liquid is projected centrifugally against the walls of a vessel through which the gas is passed, the liquid which rebounds from the walls is sprayed again. Curved pick-up pipes dip into the liquid contained in the vessel and deliver it to a rotating perforated tray, and an additional annular perforated tray is carried by the main tray outside and at a slightly lower level, so as to receive liquid which rebounds from the walls. The auxiliary tray may also be provided with scoop pipes dipping into the liquid, and alternatively its rim may be serrated. In another form, the auxiliary tray may be replaced by a series of radial projecting horizontal plates each having an upturned perforated serrated or like periphery, with or without a scoop pipe. The following edge of each plate may be upturned so as to act as a fan.—W. F. F.

Refrigeration ; Method of — F. G. Keyes, Boston, Mass., Assignor to National Automatic Refrigerator Co. U.S. Pat. 1,258,017, Mar. 5, 1918. Date of appl., Jan. 27, 1917.

A MIXTURE of an absorbent, a solvent, and a refrigerant is distilled so that the solvent and refrigerant pass into the refrigerating chamber in proportions comprising substantially a critical boiling mixture. The resulting mixture is vaporised in the refrigerating chamber and re-absorbed by the absorbent in the same proportions. (See also U.S. Pat. 1,251,538; this J., 1918, 142 A.) —W. H. C.

Dryers ; "Evacuator for cylindrical — C. L. St. Clair, Oregon City, Oreg., and J. H. Hoffman, Dansville, N.Y. U.S. Pat. 1,258,055, Mar. 5, 1918. Date of appl., Aug. 10, 1917.

A HORIZONTAL cylindrical dryer is provided with helical ribs on its inner surface, and a narrow chamber forming one end is divided by a spiral partition having several convolutions. A number of openings are provided around the circumference of the narrow chamber, each of which is connected with the end of one of the helical ribs. The narrow chamber is provided with an axial drain pipe.—W. F. F.

Heat of liquids ; Apparatus for utilising the — E. N. Trump, Syracuse, N.Y., Assignor to The Solvay Process Co., Solvay, N.Y. U.S. Pat. 1,258,165, Mar. 5, 1918. Date of appl., Mar. 7, 1916.

THE liquid is caused to flow under control through a series of connected chambers, each of which is connected with a separate compartment of an apparatus in which progressively lower steam pressures are maintained.—W. H. C.

Mixing and agitating mechanism for extractors, etc.* O. Z. Howard, New York, Assignor to The Diamond Match Co., Chicago, Ill. U.S. Pat. 1,258,331, Mar. 5, 1918. Date of appl., Sep. 14, 1916.

THE agitating device is carried on a central vertical screwed shaft by which it is rotated and at the same time moved vertically upwards or

downwards. Means are provided for automatically arresting and reversing the motion of the shaft at each limit of the vertical movement.

—W. H. C.

Heater; Solar ——. D. A. Harrison, Los Angeles, Cal. U.S. Pat. 1,258,405, Mar. 5, 1918. Date of appl., July 24, 1915.

Two headers for supply and discharge of fluid are connected by thin slanting tubes, the upper header sloping from its centre towards both ends in the direction of the opposite header. A grooved reflector is arranged behind the tubes, each tube fitting within but slightly spaced from the walls of the groove. A sheet transparent to heat rays is arranged to cover the other side of the tubes, and another reflector extends over the upper header. Means are thus provided to direct the sun's rays on to the tubes and upper header. The tubes are contracted at their outlet ends in the upper header.—W. F. F.

Gases; Apparatus for use in preparing solutions of ——. G. Braam, Rotterdam, Netherlands. Eng. Pat. 111,858, Dec. 4, 1917. (Appl. No. 17,974 of 1917). Under Int. Conv., July 25, 1916.

SEE U.S. Pat. 1,256,291 of 1918; this J., 1918, 198 A.

Waterproofing and rendering impervious to dust, bags, sacks, and the like; Method of ——. J. Gadsden, Melbourne, Australia. U.S. Pat. 1,258,104, Mar. 5, 1918. Date of appl., July 6, 1917.

SEE Eng. Pat. 109,252 of 1917; this J., 1918, 45 A.

Vessels or apparatus for use in concentration of sulphuric or other acids. Eng. Pat. 114,972. See VII.

Apparatus for concentrating solutions. U.S. Pat. 1,258,168. See VII.

Evaporating apparatus. U.S. Pats. 1,258,562 and 1,258,563. See XVIII.

Process of desiccating liquids. U.S. Pat. 1,258,318. See XIX A.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Oxidisable constituents of ——. Part I. J. I. Graham and J. Hill. Inst. Min. Eng., Sept. 14, 1917. Trans. N. Eng. Inst. Min. Eng., 1918, 68, 37—54.

PREVIOUSLY published experiments on the extraction of coal with pyridine have been made at the boiling point of the solvent, without exclusion of air. These conditions favour retention, chemical or physical, of solvent and absorption of oxygen by the coal or its constituents. Extraction experiments have been made by the authors, on coal from the Barnsley Soft seam at 40° C., under diminished pressure (60 mm. mercury), and in an atmosphere of nitrogen. A yield of 10—15% of extract was obtained after removal of solvent by distillation *in vacuo* and by washing with hydrochloric acid. The extract was a brown powder fusing on heating, partly soluble in caustic soda, insoluble in ammonia; 35—40% of it was soluble in chloroform. The residue was black, coke-like, and retained pyridine tenaciously. The capacity for absorbing oxygen of the extract, residue, and the original coal was determined by an adaptation of methods previously described (see this J., 1911, 1000), at 30 and 90° C., and in presence of air and an atmosphere containing 90% of oxygen. The absorption by the extract was negligibly small, whereas the residue displayed an avidity for oxygen almost equal to

that of the original coal. The so-called resinic constituent is thus not responsible for the spontaneous combustion of coal as commonly supposed, but rather the insoluble or cellulosic bodies. The extract, unlike those obtained by Wheeler (see this J., 1913, 969), was inert towards a photographic plate while the residue was strongly active, but this activity seems to be unconnected with the oxidisability. This activity is destroyed when the coal is coked.—H. J. II.

Intensive toluol production. II. Proposed improvements in the concentrating and refining process. Lichtenthacker. See III.

PATENTS.

Coke ovens; Regenerators for ——. E. C. R. Marks, London. From Soc. Franco-Belge de Fours à Coke, Brussels. Eng. Pat. 114,222, Apr. 13, 1917. (Appl. No. 5255 of 1917.)

Two sets of regenerators are arranged longitudinally below a battery of coke ovens, one set being heated by waste gases while the other set is heating the combustible gases. Each set comprises a central gallery divided transversely by partitions to form a row of regenerator chambers. These are filled with chequer brickwork and communicate alternately with two longitudinal flues which are arranged on each side of and parallel to the central gallery. The lower parts of the flues may also be filled with chequer brickwork, forming auxiliary regenerators, one of which may be outside the furnace setting. One of the flues may be wholly filled with chequer brickwork, and an auxiliary flue provided outside the furnace setting.—W. F. F.

Gas wash boxes. F. Thuman, London. From C. S. Chrisman, West Chester, Pa., U.S.A. Eng. Pat. 114,397, Nov. 7, 1917. (Appl. No. 16,290 of 1917.)

THE gas-inlet pipe dipping into the liquid in a wash-box is provided with a rim having a more extensive periphery, by making re-entrant spaces in the wall of the pipe. There may be two such re-entrant spaces at right angles, extending across the inlet pipe, so that in effect the pipe is divided into four branches, sector-shaped in cross-section, and separated by liquid spaces.—W. F. F.

Hydrocarbons; Art of and means for cracking ——. J. W. Coast, jun., Tulsa, Okla., Assignor to the Process Co., U.S. Pats. 1,258,190 and 1,258,191, Mar. 5, 1918. Date of appl., Mar. 22, 1917.

AT the bottom of a cracking still supported on a heating chamber, is a layer of fusible material so heavy that coke-forming substances float on its surface, a skimming device forcing them to a point above one of the end walls of the heating chamber. The contents of the still are maintained under pressure.—L. A. C.

Petroleum hydrocarbons; Apparatus for cracking ——. J. S. Cosden and J. W. Coast, jun., Tulsa, Okla., Assignors to The Process Co. U.S. Pat. 1,258,196, Mar. 5, 1918. Date of appl., Dec. 26, 1916.

SUPERHEATED vapours from a cracking chamber pass through a series of reflux condensers, the first of which is a supplementary cracking chamber into which a relatively cool hydrocarbon is sprayed. The vapours pass into another of the series into which steam is discharged. The pressure throughout the apparatus is greater than three atmospheres.—L. A. C.

Distillation or evaporation of liquids [petroleum]. Eng. Pat. 114,353. See I.

Apparatus for determining the quantity of carbon dioxide in flue-gases. U.S. Pat. 1,260,020. See XXIII.

**11B.—DESTRUCTIVE DISTILLATION ;
HEATING ; LIGHTING.****PATENTS.**

[*Peat and*] *pitch* ; *Carbonisation of* —. W. Anderson, Helensburgh, Dumbarton. Eng. Pat. 114,371, Nov. 21, 1917. (Appl. No. 8789 of 1917.)

WET peat, 100 parts, and ground coal tar pitch, 20 parts, are mixed together and passed through a pulping machine, and then formed into blocks. The blocks are dried in a stove in a current of hot air, and are then suitable for carbonisation in a retort.—W. F. F.

Electrodes for searchlights. E. A. Sperry, Brooklyn, N.Y., U.S.A. Eng. Pat. 102,971, Dec. 22, 1916. (Appl. No. 18,111 of 1916.) Under Int. Conv., Dec. 22, 1915.

THE positive electrode consists of an outer shell of highly refractory pure carbon with an inner core of volatile material, *e.g.*, about 40–60 % of cerium or other rare earth fluoride or the like, mixed with carbon. The luminosity of the flame is increased and the formation of a crater facilitated. The flame has a high resistance and an anode drop of about 13 volts. The current density in the positive electrode is such that the flame is caused to issue from the tip of the electrode or mouth of the crater. The negative electrode may be provided with a core containing carbon and an alkali chlorate or borate so as to control the negative flame.—W. F. F.

III.—TAR AND TAR PRODUCTS.

Toluol production ; Intensification —. II. *Proposed improvements in the concentrating and refining process*. F. E. Lichtenthaler, Met. and Chem. Eng., 1918, 18, 195–202. (See also this J., 1918, 174 A.)

THE present method of concentrating the toluol into crude toluol in intermittent stills and then washing and refining, is condemned as causing loss of toluol and waste of chemicals. Continuous concentration of the toluol into one fraction in a double-column continuous concentrator provided with an internal reflux system is advocated. The crude light oil is separated into crude benzol, crude toluol, and solvent naphtha. The crude toluol is then washed with sulphuric acid, water, caustic soda, and again with water, and rectified in an intermittent column still provided with direct and indirect steam heating and an internal reflux system. Automatic soda dissolvers are described and the room for improvement in the chemical washing process mentioned. Central concentration and refining stations to which the crude light oil obtained at the gas works might be sent for working up are advocated.—W. H. C.

PATENTS.

Distilling coal tar or the like ; Process and apparatus for —. W. P. Thompson, Liverpool. From P. C. Reilly, Indianapolis, Ind., U.S.A. Eng. Pat. 114,453, Mar. 19, 1917. (Appl. No. 3918 of 1917.)

**V.—FIBRES ; TEXTILES ; CELLULOSE ;
PAPER.**

Fibres ; Electrification of —. S. A. Shorter. J. Textile Inst., 1918, 9, 6–10.

WOOL is positively charged by most materials with which it is likely to come into contact in the course of manufacture. Certain other materials, however, possess the property of electrifying wool with a negative charge ; among these may be mentioned asbestos, vitreous silica, certain kinds of glass and porcelain, and certain kinds of leather, such as buff and wash leathers and raw hide, which are of the class of "oil leathers." Ordinary leathers electrify wool positively. Thus it has been proved experimentally that wool issuing from the front rollers of a French drawing frame had a strong positive charge, but after subsequently passing through the buff leather rubbing rollers, this charge was almost completely neutralised. For this reason some form of "oil leather" would be the most suitable foundation for the card clothing, while on the other hand, cotton-rubber cloth, which is frequently used, would be very objectionable from an electrical point of view. Experiments in the drawing and spinning processes showed that, under the ordinary conditions of draft, there was little or no electrification after passing between the back rollers but a strong electrification after the front rollers ; when the back rollers were driven as fast as the front rollers, so that there was no draft, the electrification after the back rollers was strongly pronounced. Hence increase of speed increases electrification because the electricity is then generated faster than it can be discharged by conductivity. An untwisted sliver emerges from the front rollers far more highly electrified than a twisted sliver, owing to the wider and closer contact between the wool and the rollers and the greater lateral displacement of fibre over fibre. When both front rollers were covered with wash leather there was still a positive though diminished

charge on the wool, although the leather generates negative electricity on the fibre. Hence the lateral motion under pressure of one fibre over another develops more positive electricity than the negative electricity generated by the contact between the wool and the rollers. Negative electricity is also lost by escape through contact with the front rollers; this might be prevented by constructing them of insulating material. Increase of pressure increases electrification. The development of electricity in the finishing process is caused mainly by contact with wood and metal; it may be considerably diminished by the substitution of other materials, such as vitreous silica, porcelain, or glass. Covering the rollers with cloth is sometimes effective, according to the nature of the materials. Investigations on the influence of humidity showed that for room temperatures of 60°–70° F. (16°–21·5° C.), a difference of 5°–6° F. (2·8°–3·3° C.) between the dry and wet bulbs gave a very favourable decrease in the electrification; this is due more to condensation of a film of moisture on the rollers than to absorption of excessive humidity by the wool.—J. F. B.

Wool containing vegetable matter; Carbonisation of —. W. Harrison. J. Textile Inst., 1918, 9, 10–13.

In the carbonisation process the loss of strength of the wool varies with the conditions of treatment. It is much more pronounced when the wool is heated at 100° C. while saturated with the dilute sulphuric acid, than when it is rapidly dried first and then heated under the same conditions. With acid at a concentration of 50 grms. per litre, little or no tendering occurs below 60° C. and if the acidified wool be first dried, it may be heated for 2 hours at 100° C. with very little tendering. With acid at 100 grms. per litre, tendering is produced during drying and subsequent heating. When tendering has been caused by drying wool with the acid in it, the wool may regain strength after washing and neutralising. This is due to the partial gelatinisation of the wool fibre by the concentrated acid and its subsequent coagulation when the acid is removed. In practice, the goods should be neutralised as soon as possible after carbonising. It is not desirable to employ an acid of more than 5% strength; the impregnated wool should be dried below 170° F. (77° C.) before heating further for the carbonisation of the vegetable matter; this last process should be as short as possible consistent with the destruction of the vegetable impurities. From experiments made to determine the consumption of acid, it is estimated that 100 lb. of air-dry wool containing 20% of vegetable matter, impregnated with 5% acid (6½% Tw.), would absorb about 10 gallons of liquid, after hydro-extracting, equal to 5 lb. of sulphuric acid. Of this, the quantity absorbed by the vegetable matter (1 lb. of acid) would be lost during crushing and "willowing." If the wool is washed in 400 galls. of water, 2·4 lb. of acid would be removed, leaving 1·6 lb. to be neutralised, with a consumption of 2 lb. of soda ash. It is noted that darkening in colour proceeds almost parallel to the degree of tendering of the wool.—J. F. B.

PATENTS.

Flax and other fibres; Method and apparatus for retting —. N. T. Bacon, Pease Dale, R.I. U.S. Pat. 1,258,983, Mar. 5, 1918. Date of appl., Apr. 26, 1917.

The process of water-retting of flax is regulated by locally checking the retting action by bubbling gas through selected portions of the retting water.—J. F. B.

Esparto or the like; Removing — from stationary digesters and the like used in paper-making. W. M. Wallace, T. Marshall, and A. Brown, Denny, Stirling, and Bertrams, Ltd., Edinburgh. Eng. Pat. 114,348, Apr. 10, 1917. (Appl. No. 4991 of 1917.) Addition to Eng. Pat. 104,578, Apr. 16, 1916 (this J., 1917, 450).

As a modification of the original method for breaking up and discharging digested material from digesters, drainage vats, and other receptacles by the hydraulic force of a jet of water, a movable nozzle having a swivel or universal joint or a flexible portion, and operated in all directions by means of a lever and rod mechanism, is inserted through the charging hole of the digester when the lid is off. The material disintegrated by the force of the water is discharged through an opening in the bottom of the digester, and a pipe passing through an orifice in the false bottom connects the upper surface of this with the discharge orifice. This passage is kept clear by a suitably disposed water-jet nozzle fixed inside the boiler and connected to the water supply when the lid is opened.—J. F. B.

Paper pulp; Process and apparatus for treating —. G. C. Howard, Tacoma, Wash. U.S. Pat. 1,258,568, Mar. 5, 1918. Date of appl., May 29, 1916.

PAPER pulp, e.g., a mixture of wood-pulp and water, is introduced into a vat and caused to flow within the influence of a pair of rapidly rotating rollers, whereby the surface friction of the rollers draws a portion of the pulp and a reduced amount of water between the rolls, causing it to rise and float upon the remainder. The height of the liquid is adjusted so that the rolls are submerged, and means are provided to prevent the flow of the heavier pulp material beyond the roll and for discharging the withdrawn pulp and water and the remainder of the water and pulp by separate outlets.—J. F. B.

Paper; Process and apparatus for regenerating old —. H. Wade, London. From Soc. Union Française des Papeteries, Lyon, France. Eng. Pat. 114,257, Aug. 16, 1917. (Appl. No. 11,784 of 1917.)

THE material is triturated in the presence of water in a vat provided with stirrers, the blades of which are inclined relatively to their plane of rotation and are arranged to overlap during rotation, so that the blades of one stirrer engage with the angular spaces of the blades of the other. The bottom of the vat is provided with projecting teeth on which the paper is torn or triturated by the stirrers. A pump withdraws pulp from the bottom of the vat and delivers it into a bucket or trough situated over the top of the vat and containing a grooved roller which rubs the pulp against grooves in the bottom of the bucket and then discharges it back into the vat. At the end of the operation the pulp is transferred to the upper end of an inclined wire screen on which jets of water are directed in a uniform manner, under constant head, from an upper tank to wash the impurities through the screen as the pulp travels down it.—J. F. B.

Paper; Process of making —. W. H. Good-enough, Camas, Wash. U.S. Pat. 1,257,996, Mar. 5, 1918. Date of appl., Aug. 29, 1917.

In the process of making news-print paper, 2 lb. of "sal soda" (sodium carbonate) is added to 1500 lb. of paper stock.—J. F. B.

Cotton and other fibre-bearing seeds; Delinting of ginned —, and the segregation and collection of the detached fibres. Defibration of the decorticated hulls of cotton and other fibre-bearing seeds, and segregation and collection of the detached fibres. E. C. de Segundo, London. Eng. Pats. 114,435 and 114,450, Feb. 28, 1917. (Appl. Nos. 10,753 of 1916 and 2975 of 1917.)

Cellulose acetate; Manufacture of —. J. Koetschet, Lyon, Assignor to Soc. Chim. Usines du Rhône, Paris, France. U.S. Pat. 1,258,913, Mar. 12, 1918. Date of appl., June 18, 1914.

SEE Fr. Pat. 473,399 of 1914; this J., 1915, 488.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Tendering of bleached (but badly scoured) vegetable yarns; Investigation of the cause of —. S. H. Higgins. J. Soc. Dyers and Col., 1918, 35—43.

FROM experiments on the washing of cream yarn goods and on the retention of chlorine and acid by cotton and linen, it is concluded that the deterioration of imperfectly bleached textile fabrics during storing is due to mineral acids which have not been completely washed out of the goods, and that the chlorine reaction of chemicked and washed cloth is due to free chlorine; no evidence was obtained that chloramines play any part in this deterioration, as suggested by Cross and Bevan (this J., 1908, 260; compare Cross, J. Soc. Dyers and Col., April, 1918). The yellowing of bleached goods on storing or on steaming is ascribed to the darkening of the melted wax, and can be prevented only by good scouring.

—F. W. A.

Dyeings fast to light; The production of —. K. Gebhard. Sealed communication, June 12, 1910. J. Soc. Dyers and Col., 1918, 34, 74—76. (Compare this J., 1910, 691.)

THREE methods are discussed whereby the fading of dyestuffs may be prevented. (1) Dislocation of the original equilibrium between the oxygen in solution and the ions of the water (the perhydroxyl ions). This equilibrium

is influenced by all other bodies in the system. When it is ascertained what kind of influence takes place under the action of light the equilibrium can be established in a direction favourable to the durability of the dyestuff by a suitable concentration of the substances present or the introduction of new substances. The equilibrium is altered to the disadvantage of the perhydroxyl ions by increasing the H^+ ion concentration in aqueous solutions of acid dyestuffs. This is effective with wool but not with cotton, as the latter reacts easily with H^+ and OH^+ and removes them, thus facilitating the generation of the unfavourable OOH ions. (2) Preventing or impeding the reaction between the dyestuff and the perhydroxyl ions. The facility of reaction may be decreased by converting the dyestuff into the least reactive state, e.g., by making it difficultly soluble. This is realised in the case of vat dyestuffs, colour lakes, and after-treatment with copper sulphate. Another method consists in diverting the reactivity of the perhydroxyl ions into other channels, e.g., by the addition of other substances more easily oxidisable than the dyestuff. Only those substances are useful which are capable of being automatically regenerated; this regeneration should be brought about by the light itself. Such catalytic reducing agents are cerium

sulphate or calcium citrate. The enzyme catalase is a substance of this order but is not practically available. (3) Transformation of the dyestuff peroxide into more stable compounds. Dyestuffs might conceivably be used which possess the property of splitting off the elements of water from the labile dyestuff-peroxyhydrates and forming the more stable dyestuff-peroxides. This dehydration may be promoted by the introduction of other substances into the system. It may also be possible to replace the peroxide oxygen in the dyestuff by other radicals which make it more stable, e.g., by reciprocal decomposition of a dyestuff-peroxide with an inorganic or organic peroxide; or the radical may be introduced directly where the dissociated oxygen attaches itself during the auto-oxidation. Such a combination is perhaps formed when dyeing reduced hydroxyanthraquinones on chrome mordants. In some cases the fibre itself may serve as a suitable radical. Fastness to light may be increased by excluding the unfavourable influence of moisture, e.g., by a layer of oil or wax, but the method has certain definite limitations.—J. F. B.

PATENTS.

Dyeing machine. H. M. Dudley, Philadelphia, Pa. U.S. Pats. (A) 1,258,203, (B) 1,258,542, (C) 1,258,543, (D) 1,258,544, (E) 1,258,545, (F) 1,258,546, Mar. 5, 1918. Dates of appl. (A) Dec. 5, 1916, (B) and (C) Dec. 22, 1916, (D) Dec. 29, 1916, (E) Jan. 11, 1917, (F) Jan. 31, 1917.

(A) THE dyeing machine comprises a receptacle in which is a fibre chamber formed by the walls of the receptacle, a perforated bottom plate having openings diverging upwards, and a perforated top plate having openings diverging downwards; means are provided for moving the top plate relatively to the bottom plate, so as to compress the fibre, and for holding it in the desired position. Below the fibre chamber is a second chamber having a perforated bottom plate with openings diverging upwards and tubes also diverging upwards integral with and opening into each of the openings of the bottom of the fibre chamber. Alternatively, a fourth perforated plate with openings diverging downwards may be spaced beneath the third plate, the tubes then connecting the openings of the third and fourth plates. A circulating device is provided for forcing liquid through the entire system. A small testing device similar and proportionate to the large one may be arranged externally, the small device being connected to the second chamber of the large one, so that the liquid passes through both machines in parallel. (B) Below the second or liquid supply chamber, a series of tapering rods converging downwards are arranged and means are provided for heating the liquid. (C) The openings in the plates are of pyramidal form and the tube chamber is provided with pyramidal tubes. (D) The openings in the plates are elongated, and below the liquid supply chamber is a plate-carrying chamber converging downwards, containing a series of plates diverging upwards, and having tapered edges. (E) The fixed plate of the fibre chamber is constructed of a series of thin blades attached to the wall of the receptacle and a reservoir is inserted in the external pump circuit. (F) A series of members converging upwards is provided above the movable top plate of the fibre chamber.—J. F. B.

Cotton fabrics; Treatment of —. O. Klausner, Assignor to Akt.-Ges. Ciland, Herisan, Switzerland. U.S. Pat. 1,258,225, Mar. 5, 1918. Date of appl., Aug. 12, 1916.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Boric acid; Ignition of —. C. R. Bagshaw. Analyst, 1918, 43, 138—139.

To ascertain whether boric acid could be determined in boric acid powder and boric acid ointment by igniting the sample and weighing the residual boron trioxide, a number of experiments were carried out. Boric acid ointment known to contain 10% of the acid yielded 5.11% of boron trioxide, equivalent to 9.06% of boric acid; this residue of boron trioxide decreased in weight continuously on further heating. Boric acid itself should yield 56.4% of boron trioxide on ignition, but the amount found by the author varied from 52.6 to 55.1% according to the conditions under which the substance was heated.

—W. P. S.

Argon; Preparation of — in the laboratory. M. Bodenstein and L. Wachenheim. Ber., 1918, 51, 265—270.

ARGON is recovered from commercial oxygen, made from the air, by combustion with hydrogen. The process described is an adaptation of Ger. Pat. 295,572 (see Fr. Pat. 473,985; this J., 1915, 717) to laboratory requirements. (See further, J. Chem. Soc., 1918, ii., 166.)—J. C. W.

PATENTS.

Sulphuric or other acids; Vessels or apparatus for use in the concentration of —. S. J. Tungay and G. B. Haughton, London. Eng. Pat. 114,072, May 23, 1917. (Appl. No. 7118 of 1917.)

In the concentration of sulphuric or other acid, the liquid flows over square or oblong trays arranged in cascade and constructed of acid-proof metal, passive iron, lead, fused quartz, pottery, glass, or the like. The trays are provided with longitudinal or transverse channels or corrugations to increase the heating surface and prevent deposition of solid matter. (Reference has been directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 4391 of 1875, 18,751 of 1890, and 9514 and 13,927 of 1893; this J., 1891, 240; 1893, 690; and 1891, 636.)—W. F. F.

Acetic acid from acetic aldehyde; Manufacture of —. H. Dreyfus, Basle, Switzerland. Eng. Pat. 108,159, Apr. 23, 1917. (Appl. No. 5683 of 1917.) Under Int. Conv., Apr. 27, 1916.

In the oxidation of acetaldehyde to acetic acid by air or oxygen as described in Eng. Pat. 105,065 of 1917 (this J., 1918, 180 A), the best temperature is found to be between 150° and 250° C., preferably between 150° and 200° C. Suitable catalysts are: Platinum, copper and its compounds, chromium compounds, iron, uranium

oxide, vanadium oxide, cerium oxide, etc. Although catalysts facilitate the reaction, they are not necessary for complete oxidation.—L. A. C.

Concentrating [phosphoric acid] solutions; Apparatus for —. W. J. Wayte, New York. U.S. Pat. 1,258,168, Mar. 5, 1918. Date of appl., Feb. 20, 1917.

A SHALLOW tank divided into compartments and provided with wheels is supported below a fixed vapour hood so that it may be raised into contact with the lower part of the hood or lowered on to a truck and wheeled aside. Heating coils supported from the fixed hood depend into the tank, one into each compartment, when it is in its raised position. The apparatus is intended more especially for the concentration of a solution of phosphoric acid.—W. H. C.

Kelp char, etc.; Process of and apparatus for treating — [to obtain alkali salts]. (A) F. Van D. Crusier, Oswego, N.Y., and (B) F. Van D. Crusier, Oswego, and O. Z. Howard, New York, Assignors to The Diamond Match Co., Chicago, Ill. U.S. Pats. (A) 1,258,320 and (B) 1,258,321, Mar. 5, 1918. Dates of appl., Aug. 10 and Sept. 14, 1916.

At the bottom of each of a series of vats placed at different levels is a valved discharge opening leading to the vat below and also lateral outlets covered by strainers. The kelp char is extracted in the top vat by extraction liquor from the succeeding vats, the solid matter being allowed to settle and the liquor drawn off for concentration; a further quantity of liquor is then added and the material flushed into the second vat, this process being repeated down the series until extraction is complete.—L. A. C.

Alkali chlorides; Process for the electrolysis of —. R. van Hasselt, The Hague, Netherlands. U.S. Pat. 1,259,683, Mar. 19, 1918. Date of appl., Oct. 12, 1916.

See Eng. Pat. 101,140 of 1916; this J., 1916, 1109.

Preparation of anhydrous sulphide of zinc. Eng. Pat. 106,489. See XIII.

VIII.—GLASS; CERAMICS.

Glass; Analysis of —. L. Ronnet. Ann. Falsif., 1918, 11, 26—31.

To determine silica, iron, aluminium, manganese, calcium, magnesium, potassium, and sodium in glass, the author employs mainly the usual methods of analysis. Iron and aluminium are precipitated together by a basic precipitation and then separated from one another by dissolving in hydrochloric acid and boiling with sodium thio-sulphate, the iron being converted into a soluble double thiosulphate of iron and sodium, whilst the alumina is precipitated together with sulphur. Potassium and sodium are weighed together as their chlorides and the potassium is then determined by the perchlorate method. (See also J. Chem. Soc., June, 1918.)—W. P. S.

PATENTS.

Glass-gathering mechanism. The Westlake European Machine Co., Assignees of A. Kadow, Toledo, Ohio, U.S.A. Eng. Pat. 112,613, June 18, 1917. (Appl. No. 8758 of 1917.) Under Int. Conv., Jan. 11, 1917.

Glass ware; Manufacture of hollow — and machinery therefor. T. B. Kitson and G. O. Tague, Leeds. Eng. Pat. 114,477, Apr. 5, 1917. (Appl. No. 4927 of 1917.)

IX.—BUILDING MATERIALS.

PATENTS.

Stones; Manufacture of metal-coated artificial —. H. Welte, Znaim, Austria. U.S. Pat. 1,258,282, Mar. 5, 1918. Date of appl., Nov. 10, 1915.
SEE Eng. Pat. 17,862 of 1915; this J., 1917, 139.

Mortar; Manufacture of —. J. Joachim, Berlin, Assignor to Mortelwerk Joliet Ges. m. b. H., Waidmannslust, Germany. U.S. Pat. 1,259,211, Mar. 12, 1918. Date of appl., Aug. 5, 1913.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Steel ingots; Defects in —. J. N. Kilby. Iron and Steel Inst., May, 1918. [Advance copy.] 24 pages.

EXPERIENCE shows that the variations in casting temperatures are not as great as usually supposed, and that the speed of pouring has a greater influence on the cracking of ingots. The teeming time for a 7200 lb. ingot is given as six minutes; if it be less than three minutes 80% of the ingots will show cracks on rolling. The addition of 8 to 10% of lime (or 6 to 8% of magnesia) to acid open-hearth slags is recommended as giving a reduced content of ferrous oxide, thereby enabling the slag to remove more extraneous matter present in the steel. The amount of manganese remaining in the metal is proportional to the lime content of the slag.—C. A. K.

Steel; Effects of cold working on the elastic properties of —. J. A. Van den Broek. Iron and Steel Inst., May, 1918. [Advance copy.] 41 pages.

MILD steel was subjected to cold stretching, compression, and twisting, and afterwards tested with reference to its elastic properties. It was found, contrary to accepted opinion, that cold stretching does not lower the elastic limit in compression, and the effects of cold working are probably a function of the strains and are independent of the stresses involved in the process. When a mild steel is cold worked and properly heat treated, the elastic limit may be raised more than 100% when tested in the same direction as the applied strain. Tempering at 100° C. to 300° C., or ageing the cold-worked steel, tends to improve the elastic properties. Application of heat merely accelerates the effect of time. Cold working breaks up the coarser crystalline structure and planes of weakness, with formation of amorphous steel, and after ageing, the elastic limit is not reached until a greater stress than that at which cold working is discontinued is attained. The beneficial effect of cold working is permanent.—C. A. K.

Pearlite [in steel]; Effect of cold work on the divorce of —. J. H. Whiteley. Iron and Steel Inst., May, 1918. [Advance copy.] 9 pages.

By annealing cold-worked pearlitic steels a little below the critical point (690° C.), the values for combined carbon as given by the Eggertz colour test are considerably increased as compared with the unstrained metal. At 500° C. pearlite showed a tendency to break up, and at 680° C. the divorce was completed in less than two hours, the cementite then occurring in rounded particles uniformly distributed. The pearlite in an unstrained steel was practically unaltered. The granular structure of the cementite is similar to the "granular pearlite" in tempered steels.—C. A. K.

Steel; Constitution and occurrence of non-metallic inclusions in —. A. McCance. Iron and Steel Inst., May, 1918. [Advance copy.] 48 pages.

ATTENTION is drawn to the important part that non-metallic inclusions play as a source of weakness in stressed materials. Ziegler's suggestion that non-metallic inclusions are soluble in steel is not supported and their practical importance is concerned with their existence as suspensions. In consequence of this they do not obey the laws of segregation governing other elements in solution in liquid steel, but their ultimate position is determined by secondary influences such as convection currents or local movements of crystallisation. The probability of particles of 0.001 cm. diam. rising to the surface of an ingot is practically nil, but coalescence occurs during the solidification of the last portions of metal, the suspensoids thereby being crowded together. Consequently the average size of particles found in the solid ingot is always larger than that of the particles occurring in the liquid steel. The opinion is expressed that the prevention of sulphur red-shortness by manganese is due to manganese sulphide being insoluble and therefore precipitating the sulphur out of solution in the steel. In commercial steels sulphur inclusions may be composed of manganese sulphide but not of iron sulphide even in solid solution. The eutectic of MnO—SiO₂ solidifies at about 1180° C. with a composition of 41% SiO₂ and 59% MnO. As most of the silicates isolated from steels have approximately the same percentage of silica it is concluded that they belong to the most easily fusible class, alumina and iron oxide making up deficiency in manganese oxide. Consideration of the system iron oxide-silica indicates that there is probably a physical equilibrium between Fe₂O₃, FeO, and SiO₂ independent of their chemical grouping. High working temperatures are advocated to minimise inclusion dangers on both physical and chemical grounds. Inclusions of an adventitious nature are chiefly chips of refractory material with which the steel comes in contact. Manganese silicate shows a selective solubility for the alumina in firebrick inclusions, and the interaction between firebrick and steels containing manganese has a distinct bearing on the wear of ladle nozzles and runners conveying steel to the moulds. Hydrofluoric acid may be used as a substitute for Stead's cupric reagent (this J., 1915, 616) for the identification of phosphorus, especially in cast samples.—C. A. K.

Steel; Inclusions in — and ferrite lines. J. E. Stead. Iron and Steel Inst., May, 1918. [Advance copy.] 6 pages.

EXPERIMENTS were made to determine whether or not non-metallic inclusions in steel induce ferrite to crystallise around them. In no case did quartz, magnesia, lime, basic open-hearth slag, cyanonitride of titanium, or manganese sulphide inclusions, artificially introduced into a steel bar, lead to development of a ferrite envelope, when the bar was heated to and slowly cooled from about 1200° C. Fluorspar proved an exception in the case of 0.16 and 0.31% carbon steels, and mill scale and slags containing iron oxide wholly or partially decarburised the adjacent metal. Hermetically sealed cavities made in steel did not induce formation of ferrite. The influence of phosphorus was shown by similarly heating and cooling two forged steels, containing 0.07 and 0.3% P respectively. Before heating both showed white ferrite bands or lines round the non-metallic inclusions, but after the slow cooling from 1200° C. these were absent, due to the concentration of the phosphorus in the inclusions being reduced by inter-diffusion at that temperature (see following abstract). Pure slag particles,

free from phosphorus, were not surrounded by a ferrite layer, and the presence of such ferrite is associated with a high phosphorus inclusion.

—C. A. K.

Iron, carbon, and phosphorus. J. E. Stead. *Iron and Steel Inst.*, May, 1918. [Advance copy.] 24 pages.

THE diffusion of phosphorus, in solid solution, in iron has been noted in a cast alloy containing about 3% C and 0.3% P. In the original specimen the phosphorus was associated with ferrite. When the steel was heated to 960° C. and quenched in water, it was found that carbon had diffused into the ferrite of lower phosphorus content, but on slow cooling the carbon returned to the parts still lower in phosphorus. When heated to 1200° C. and slowly cooled, the phosphorus interdiffused and became more evenly distributed and on cooling no separation was effected. It is suggested, as the solution pressure of carbon increases rapidly with increase in temperature, and as iron phosphide is mobile at a high temperature, that if an alloy containing phosphorus is carburised at a high temperature, the entrance of carbon into solid solution would increase the internal tension and drive the phosphorus into less carburised areas. Concentration of phosphorus in these areas would proceed until the tension of the phosphide in solid solution balanced the tension of carbide in solid solution at any given temperature, and if that temperature exceeded the formation point of the liquid ternary eutectic Fe—C—P, the internal tension of the high phosphide ferrite would become so great that the phosphide would be forced out of solid solution, forming a eutectic liquid. This temperature is given as 1200° to 1300° C., from trial on an alloy containing 0.5% P, an abnormal figure for a commercial steel. In a tentative investigation to determine the critical point of solution of iron phosphide in iron, it was found that solution of phosphide in phosphorus-free iron had occurred at 700° C., but in iron practically saturated with phosphide in solution the temperature is higher. Conversely, observations on the temperature at which iron phosphide (Fe_3P) falls out of solid solution shows that the amount present is a vital factor. Methods for the detection of phosphorus in solid solution are given. (See also this J., 1915, 616.)—C. A. K.

Hypo-eutectic steel; Transformation of martensite in —. M. Matweiff. *Rev. Soc. Russe de Mét.*, 1916, I., 149—155. *Rev. Mét.*, 1918, 15, Ext., 44—48.

OBSERVATIONS of the micro-structure of hypo-eutectic steel containing C 0.26—0.30%, Mn 0.60—0.90%, Si 0.2—0.4%, S less than 0.035%, and P less than 0.05%, were made after hardening and tempering under different conditions. A cylindrical specimen was heated so that the temperature varied from the melting point at one end to a comparatively low temperature at the other end, and the specimen was then quenched in cold water so that the hardness varied from a maximum at one end to a minimum at the other. Micrographs are shown, taken at five zones along the specimen measuring from the hardened end, and these show (1) the presence of martensite in large needles, (2) martensite in small needles, (3) that the pearlite has been converted into martensite but the ferrite has not been dissolved in the latter, (4) the simultaneous presence of pearlite, ferrite, and martensite, and (5) the presence of pearlite and ferrite only, indicating a soft metal. The effect of tempering, at various temperatures, specimens hardened as above was then observed. When the reheating temperature was below 300° C. no change took place, but above

300° C. zones (1) and (2) showed the presence of sorbite, zones (3) and (4) showed the presence of sorbite in place of amorphous martensite, and zone (5) showed no change. Tempering at 500°—600° C. showed no important changes, but at 750° C. zone (1) showed deposits of free ferrite on the surface of the grains of martensite, indicating overheating, and zones (2) and (3) showed the texture due to normal heating. It is concluded that steel hardened at a very high temperature would show little strength and ductility owing to the coarse martensite structure, and that the breaking strength increases to a maximum as the hardening temperature is reduced to about 800° C. When the steel is subsequently tempered, the breaking strength increases with rise of the temperature of reheating.—W. F. F.

Manganese [in steel]; Volumetric determination of — by means of sodium arsenite. F. Ibbotson. *Chem. News*, 1918, 117, 157—158.

ATTENTION is directed to a source of error in the determination of manganese in steel when the metal is dissolved in nitric acid, the manganese oxidised to permanganate, and the latter titrated with sodium arsenite solution. In the presence of nitric acid, the arsenite solution has a reducing value about 33% more than it has when used for titrating a permanganate solution free from nitric acid. Reliable results are obtained, however, if the arsenite solution is standardised against permanganate under the conditions obtaining in the actual determination, i.e., in the presence of nitric acid, etc.—W. P. S.

Nickel-chrome steel; Allotropic transformations and microstructure of —. A. M. Masloff. *Rev. Soc. Russe de Mét.*, 1915, I., 495—515. *Rev. Mét.*, 1918, 15, Ext., 37—44.

EXPERIMENTS were made on samples of nickel-chrome steel to determine separately the effect on the micro-structure of the maximum temperature of heating, rate of heating and cooling, and variations in the proportions of nickel and chromium. The specimens tested contained approximately C 0.5%, Mn 0.3%, Si 0.25%, P 0.03%, while the proportions of chromium and nickel were varied as desired from 0.92% to 2.03% and 1.07% to 5.53%, respectively. The influence of the maximum temperature of heating on the transformation or recalescence point observed during subsequent cooling was shown to be practically negligible if the rate of cooling was not greatly varied, and the influence of the rate of heating was also negligible. Variation in the rate of cooling had considerable effect. When the rate of cooling between 750° and 550° C. varies from 1° to 32° C. per minute, the steel shows the same transformation point as if chromium were absent, and contains troostite and pearlite. The transformation point falls as the rate of cooling increases, and becomes less clearly marked, while the specimen shows the structure of pure troostite changing with the most rapid cooling to martensite. The presence of nickel was found to reduce the temperature at which the solid solution of carbon in iron decomposes, while chromium was found to have a smaller but opposite effect. Chromium, however, retards the decomposition of this solid solution. Steel containing a small amount of nickel but sufficient chromium may therefore be hardened by cooling in air.—W. F. F.

High-speed steel; Researches on —. M. Yatskevitch. *Rev. Mét.*, 1918, 15, 65—112.

EXPERIMENTS were made to determine the effect of varying heat treatment upon the transformation points, the general form of the heating and cooling curves, the micro-structure, and the hardness of a sample of high-speed steel. The

sample contained W 18.20%, Cr 3.00%, C 0.62%, V 0.95%, Si 0.27%, Mn 0.38%, S 0.025%, and P 0.025%. The heating and cooling curves were obtained by the Saladin-Le Chatelier apparatus, in which a neutral body was employed in addition to the sample, the two registering thermocouples being connected differentially according to the Roberts-Austen method so that differential curves were obtained. The effect of the rate of cooling was also observed in three series of experiments in which the cooling took place (1) within the heating tube, (2) in the air, and (3) in a current created by a fan. Series of heating curves are shown in which the maximum temperature of the specimen varies from 700° C. to 1050° C. and these show changes of curvature at about 400°—500° C. and points of inflexion at 773° C. and 856° C., attributed to three distinct exothermic reactions. The corresponding cooling curves show in general (1) only a single point of inflexion or transformation point, which falls as the maximum temperature increases, except that with the higher maxima a second lower point of inflexion appears at about 500° C.; (2) points of inflexion similar to (1) except that the lower point of inflexion varies from 250° to 370° C. and appears with the lower maximum temperatures, and (3) (rapid cooling) similar curves with more strongly marked lower point of inflexion, the upper point disappearing with the higher maximum temperatures. These results show the importance of the time factor in the hardening and tempering of high-speed steels. Corresponding curves are given in which the maximum temperature is above the melting point, and also comparative curves showing the variation in hardness with temperature. A number of micrographs are given showing the effect on hardness of varying heat treatment, and varying rates of cooling. The presence in the steel of various combinations of the constituent elements can be shown by suitable choice of etching reagents. The higher maximum temperatures show the increased production of particles which resist the action of reagents.—W. F. F.

Cobalt steel; Determination of cobalt and nickel in —. W. R. Schoeller and A. R. Powell. *Iron and Steel Inst.*, May, 1918. [Advance copy.] 5 pages.

THE method is based on the separation of hexamine cobaltous and hexamine nickelous iodides (this J., 1917, 720), the process being modified by the previous removal of iron and chromium. 2 grms. of drillings is dissolved in 30 c.c. each of hydrochloric and nitric acids, and evaporated to dryness. 2 c.c. of sulphuric acid (1:1), a little hydrochloric acid, and 25 c.c. of water are added, and the cooled solution titrated with 20% sodium carbonate solution, using a thiocyanate solution as a spot indicator. When the red colour grows faint, the solution is made up to 200 c.c. and filtered. 100 c.c. of the filtered solution is heated to boiling with 1—2 c.c. of nitric acid, and treated with 25 c.c. of bromine water and an excess of caustic soda. The precipitate contains all the cobalt and nickel and traces of iron, chromium, and manganese. It is filtered off, dissolved in hydrochloric acid, and the solution evaporated with a few c.c. of nitric acid, and treated with a saturated solution of 1 gm. of tartaric acid and 50 c.c. of ammonia (sp. gr. 0.88), followed by a saturated solution of 4 grms. of potassium iodide. The iodides of cobalt and nickel, after washing with ammoniacal potassium iodide solution, are dissolved in 10 c.c. of hydrochloric acid (1:1) with addition of a little sodium sulphite, the solution treated with 5 c.c. of 25% ammonium phosphate solution, and the cobalt precipitated by addition of ammonia until the blue amorphous precipitate becomes pink and crystalline. The

cobalt-ammonium phosphate is titrated with *N/5* sulphuric or nitric acid until the precipitate disappears (see this J., 1916, 656). Manganese if present is precipitated with the cobalt. It is determined in the liquid, after the titration, by the persulphate method, and a correction applied. 1 c.c. of *N/5* acid = 0.0059 gm. Co. The filtrate from the cobalt-ammonium phosphate is cooled and titrated with a freshly standardised solution containing 10 grms. of sodium cyanide, 2 grms. of caustic soda, and 1 gm. of silver nitrate, until the silver iodide precipitate at first produced redissolves.—C. A. K.

Calcium sulphate; Influence of — on the action of water on iron. P. Medinger. *Ber.*, 1918, 51, 270—271.

THE fact that gas and water pipes suffer corrosion particularly severely when they lie in heavy clays containing calcium sulphate is due to the depression of the ionisation of the bicarbonates and consequent liberation of more hydrogen ions from the carbonic acid. This influence of the sulphate on a solution containing calcium bicarbonate and free carbonic acid may be demonstrated by means of litmus.—J. C. W.

[*Gold amalgamation.*] *Discussion on mercury losses.* J. Chem., Met., Min. Soc., S. Africa, 1918, 18, 173—180.

H. RUSDEN stated that free mercury exists in black sand in the globular and floured forms. The globular mercury can be recovered from the tube mill discharge in a Batea pan. In the subsequent cyanide treatment a portion of the mercury is dissolved, and precipitated by zinc, a zinc-gold amalgam being sometimes formed. The average recovery of mercury from black sand is 2 lb. per ton.

H. A. White explained that coarseness of pulp as well as the mineral composition (especially the presence of chlorite, talc, clay, and certain sulphides) may have a considerable influence upon the mercury consumption. He suggested leaching black sand residues with sodium sulphide and precipitating the solution with aluminium powder. If the supply of mercury should become inadequate, it might become necessary to adopt blankets, and cyanide the finely ground coarser metal thus caught. A few experiments bearing upon the adhesion of gold to grease tables were made on the mill discharge stream. By removing the grease and concentrate every two hours, the recovery was 28% of that obtained by amalgamation. Better results might be expected from a continuous grease belt system. In another test, a plate was divided into three equal longitudinal strips: the middle one was covered with canvas, the outside ones with blanketing. In 24 hours the recovery on canvas was 70, and that on the blankets 40%, of the recovery by amalgamation.

F. Wartenweiler stated that, by the use of Batea pans, the mercury content of black sand had been reduced from 0.15—0.75 to 0.18%. Gold precipitates taken from extractor boxes assayed 0.15—0.25% Hg.—W. R. S.

[*Gold-bearing concentrates; Cyaniding versus smelting* [of —]. A. E. Drucker. *Eng. and Min. J.*, 1918, 105, 454.

STATISTICS are given showing the importance of cyaniding raw gold-bearing concentrates on the spot. Fine grinding in cyanide solution to pass a 200-mesh screen is necessary for an extraction of 90—95% of the gold within 24—48 hours. The raw concentrates obtained at Maibong, Korea, were treated by fine grinding in a cyanide solution, air agitation, decantation, and filter pressing, at a minimum cost of \$4.17 per ton and a gold

extraction of 91.2%. The concentrates were formerly shipped to America for smelting at a total cost for marketing of over \$30 per ton.—W. F. F.

Chalcopyrite; Flotation of — in chalcopyrite-pyrrhotite ores of S. Oregon. W. H. Coghill. Tech. Paper 182, U.S. Bureau of Mines.

The separation of these sulphide ores, which have nearly the same density, is difficult by ordinary methods of ore dressing. Flotation experiments gave favourable results. The ore was ground to pass a 200-mesh sieve. The oil used ("Flotco No. 1") gave a steep surface tension curve and was characterised by high solubility. The water was neutral. The extraction of copper attained was 78.7% and a concentration ratio of 12:1, while the product contained 27.4% of copper. The gold which is present in the chalcopyrite, passed into the tailings in the process, but seems to be easily recoverable by amalgamation. An insoluble oil is to be avoided as also the introduction of iron from the crushing plant.—H. J. H.

Copper minerals; Determination of — in partly oxidised ores. C. E. Van Barneveld and E. S. Leaver. U.S. Bureau of Mines. Eng. and Min. J., 1918, 105, 552—553.

It is important in ore flotation to be able to distinguish between copper present as sulphide and oxide minerals. Extraction by 5% cold sulphuric acid does not effect a quantitative separation of oxidised compounds. Metallic iron from the crushing machinery is dissolved and causes deposition of metallic copper. Only one-half of the copper in cuprite passes into solution, while some chalcopyrite, bornite, and chalcocite are also dissolved. Neither does a 5% solution of ammonia give satisfactory results. The sulphides are dissolved to a slight extent, while the formation of gelatinous silica interferes with the solution of oxidised minerals. These are also defects of Hunt and Thurston's method (Colorado School of Mines, May, 1917, 7, 157) based on the extraction of the oxidised minerals with alkaline sodium tartrate and alkaline ammonium sulphate. Extraction with dilute sulphurous acid is considered to give the most correct results:—2 grms. of ore, pulped to pass a 100- or 150-mesh sieve, is shaken with a solution containing 3% of SO_2 for one-half to two hours. The insoluble residue is filtered off and washed with dilute sulphurous acid, and the filtrate then contains all the copper present as oxide, carbonate, or silicate in the ore. After acidification with nitric acid the copper can be estimated electrolytically. Sulphide minerals are not affected. Metallic iron—up to 3%—is rapidly dissolved and has no influence if excess of sulphurous acid is present. No interference is caused by the formation of gelatinous silica and ores of any grade can be dealt with. Metallic copper must be determined separately.—H. J. H.

Sulphur [copper sulphide] and copper oxide determination. C. G. Maier. Eng. and Min. J., 1918, 105, 372—373.

IN a method of determining accurately the proportions of copper sulphide and "oxide" or acid-soluble copper in a sample of copper ore, especially for use in flotation processes, 1 to 3 grms. of the ore is heated to 80°–90° C. with 50 c.c. of 4% sulphuric acid for 30–45 minutes. The solution is cooled and 1 to 5 c.c. of clean mercury added and mixed thoroughly with the residue, so that it amalgamates with the metallic copper present. The solution is decanted and the ore washed out of the beaker, leaving the mercury, which contains all the original metallic copper and also any copper reduced from cuprous

oxide. The solution is filtered and the copper determined separately in the filtrate and residue, preferably by the iodide method. The copper in the residue represents the sulphide and that in the solution the "oxide" or acid-soluble copper.—W. F. F.

Sulphur analysis [in ores]; Method of —. F. G. Hawley. Eng. and Min. J., 1918, 105, 385—386.

A METHOD is described for estimating sulphur gravimetrically in ores and furnace products by oxidation to sulphate and precipitation as barium sulphate, which avoids the difficulties usually experienced in oxidising mattes and calcines, or ores containing much copper or zinc sulphide. 0.5–1.0 gm. of the sample is treated with 10 c.c. of a 20% solution of sodium chlorate, and 7–15 drops of a mixture of equal parts of bromine and glacial acetic acid. 10 c.c. of nitric acid nearly saturated with potassium chlorate is then added and the mixture agitated. After 2 or 3 minutes the sulphur is oxidised, and the mixture is then evaporated to dryness. The residue is cooled, 5 c.c. of 60% hydrochloric acid added, and after heating till all soluble substances are dissolved, the solution is diluted to 150 c.c. and neutralised with ammonia. If lead is present, about 1 gm. of ammonium carbonate is also added, the mixture boiled for 1 minute, filtered, and the precipitate washed thoroughly. The filtrate is heated to expel ammonia, hydrochloric acid added in excess, and then about 15 c.c. of a 10% solution of barium chloride. The mixture is boiled for 10 minutes, allowed to settle, filtered, and the barium sulphate ignited and weighed. This method avoids the formation of globules of free sulphur during the oxidation by preventing heating of the solution. Potassium chlorate may be used instead of the sodium salt and is more stable in nitric acid, but much less soluble in water.—W. F. F.

Zinc [smelting]; Fine-grinding and porous-briquetting of the charge [in] —. W. M. Johnson. Amer. Inst. Min. Eng., Feb., 1918. Eng. and Min. J., 1918, 105, 370—371.

A PROCESS is described which reduces the consumption of coal in a zinc-smelting retort. The excess of about 400% above the amount theoretically necessary, which is used at present, is employed to secure a high reducing power, good heat-conductivity, and porosity of charge, and a residue free from slag, and the coal is used in large pieces. In experiments with zinc ore and coal dust ground to 80-mesh fineness, it was found possible to reduce the coal consumption, but the charge was so dense that it obstructed the passage of zinc vapour. Good results were obtained by the addition of broom straw to give porosity. The percentage of coal was reduced successively from 60% to below 30% of the ore, the lower amount effecting a complete reduction of the ore and avoiding the production of slag. The poor conductivity of the finely ground charge is avoided by briquetting the mixture into pieces of about 0.5 in. diameter. Assuming the present cost of zinc ore smelting to be \$17 per ton, it is estimated that a net saving of \$9.47 would be effected by this process.—W. F. F.

Copper-nickel series of alloys; Potential measurements on the — and some observations on brasses. N. T. Gordon and D. P. Smith. J. Phys. Chem., 1918, 22, 194—215.

COPPER-NICKEL alloys are shown to be very regular in electrochemical behaviour, and the potential values are reproducible and constant to within 3 millivolts, remaining so for many hours. Alloys containing 6.8, 10.9, 65.5, 74.3, 83.1, and 94.7% Cu were employed, and each

exhibited potential differences against mixed solutions of copper and nickel sulphates, N/1 in combined strength, which, when plotted against the logarithms of the copper concentration, gave curves of a straight line character, and, with one exception, with a similar slope. Polished surfaces increase the tendency to give ions to the solution, whilst coarser grinding with emery produces small accidental variations from the steady values obtained with annealed surfaces.

Further experiments with Cu-Zn alloys (see J. Phys. Chem., 1916, 20, 228) have shown these to be variable as regards electromotive force, and lend confirmation to suggestions made by other authors (Roberts-Austen, this J., 1898, 214; Carpenter and Edwards, this J., 1911, 133) of unexplained changes to which these alloys are subject. (See also J. Chem. Soc., June, 1918.)—B. N.

Manganese; Estimation of — in aluminium alloys and dust. J. E. Clennell. Eng. and Min. J., 1918, 105, 407–410.

THE dust, freed from grease, is dissolved in dilute hydrochloric acid, the solution filtered, and the hot filtrate treated with excess of hot caustic soda to redissolve the alumina. The precipitate containing iron, manganese, copper, and magnesium is filtered off and washed. Separation of the iron from the manganese by ammonia and ammonium chloride was found to be unsatisfactory even after successive redissolving and precipitating. The method of separation by ammonium carbonate described by Fresenius ("Quantitative Analysis," 7th Ed., Vol. 1., p. 437) was satisfactory but tedious, and the zinc oxide method described by Low ("Technical Methods of Ore Analysis," 5th Ed., p. 162) was with some modifications found to give a perfect separation of the manganese. The manganese in the pure hydroxide may be estimated by oxidation of oxalic acid (Low, *loc. cit.*), or by Volhard's method depending on the titration of a manganous salt with permanganate (Low, *loc. cit.*, p. 167). The following much simpler method does not involve the separation of the manganese from all other metals. 1 grm. of the sample is heated with 50 c.c. of 50% nitric acid, and finally boiled to expel oxides of nitrogen. The solution is filtered, the residue washed, placed in a nickel crucible, dried, ignited, and the ash covered with sodium peroxide. The mixture is fused and the product dissolved in water and added to the previous nitric acid solution. The mixture is boiled and about 1 c.c. of standard silver nitrate solution added to remove chlorides. 0.1 grm. of lead peroxide is added for each estimated 0.1 grm. of manganese present, the mixture boiled, cooled, made up to 100 c.c., and filtered. 50 c.c. of the filtrate is titrated with standard sodium arsenite. The sodium arsenite solution is made by dissolving 10 grms. of arsenious oxide and 30 grms. of sodium carbonate in boiling water, cooling, and diluting to 1000 c.c.; 62.5 c.c. of this solution is diluted to 1000 c.c.: 1 c.c. of the final standard solution is equivalent to about 0.00025 grm. of manganese. The arsenite solution is standardised against the known manganese content of a standard potassium permanganate solution, or preferably against a standard manganous nitrate solution, obtained by dissolving pure manganous carbonate in nitric acid. Results of tests are given showing that the method is reliable and not affected by the presence of ferric iron or aluminium.—W. F. F.

Bismuth; Determination of — in lead bullion. D. W. Jessup. Eng. and Min. J., 1918, 105, 603–604.

FIVE grms. of filings is dissolved in a flask in 60 c.c. of nitric acid (1 : 4); the solution is heated with 15 c.c. of sulphuric acid until fumes are

evolved and then directly over a blast lamp for a few minutes; after slight cooling, 40 c.c. of hot water is added and the solution rapidly decanted through a filter. To the residue are added 10 c.c. of sulphuric acid and 40 c.c. of water. The mixture is agitated and decanted, the residue again heated with 10 c.c. of sulphuric acid over a free flame until dense fumes are evolved, and treated as before. The combined filtrates are partly neutralised with ammonia, precipitated with hydrogen sulphide, the sulphides extracted with sodium sulphide and cyanide in succession, and the residue dissolved in 10 c.c. of nitric acid (1 : 1). The solution is evaporated just to dryness, the residue dissolved in a few drops of hydrochloric acid (1 : 1), and the solution diluted with 500 c.c. of warm water. After standing overnight, it is decanted through a tared filter, the latter washed, and the precipitate weighed as BiOCl. In the bismuth assay of lead ores and slags, the lead sulphate is treated as described above to extract all the bismuth.—W. R. S.

PATENTS.

Iron; Manufacture of — [from black oxide scale]. F. Perry, and Metalloids, Ltd., Tipton. Eng. Pat. 114,237, May 18, 1917. (Appl. No. 7184 of 1917.)

SCALE or black oxide of iron is heated in an atmosphere of Mond gas or similar gas, preferably after the latter has been purified from sulphur and hydrocarbon gases. The resulting metal is purer than that from which the scale is originally produced.—T. H. B.

Grey cast iron; Manufacture of —. W. B. Hamilton, Sheffield. Eng. Pat. 114,328, Mar. 21, 1917. (Appl. No. 4112 of 1917.)

IRON or steel, either solid or molten, is introduced into an acid-lined electric furnace, and limestone, lime or other metallic oxide, and sand are added to form a slag, carbonaceous material being also added, either when charging, or during melting, or to the slag.—T. H. B.

Steel [heating] furnaces [; Gas-fired —]. The Richmond Gas Stove and Meter Co., Ltd., Warrington, and J. Thompson, Sheffield. Eng. Pat. 114,359, May 14, 1917. (Appl. No. 6821 of 1917.)

A FURNACE for heating small articles, *e.g.*, steel cutters, is made of refractory brickwork and is circular in horizontal cross section. Heating burners are arranged tangentially at the upper and lower parts of the chamber. A sliding door is provided at one side, having a central opening to enable the heated articles to be manipulated, and the hot gases to escape. To facilitate exchange of articles to be heated, a central tubular support is provided in the floor of the chamber, into which supporting blocks of various sizes may be fitted.

—W. F. F.

Zinc powder; Method of converting — into liquid zinc. Norsk Elektrisk Metalindustri-Aktieselskap, Sarpsborg, Norway. Eng. Pat. 105,558, Apr. 5, 1917. (Appl. No. 4954 of 1917.) Under Int. Conv., Apr. 8, 1916.

ZINC powder is subjected to a rubbing action without the use of fluxes, in a movable, internally heated furnace, *e.g.*, in a rotating electric furnace.

—T. H. B.

Copper; Process for tempering and hardening —. J. A. Morterud, Duluth, Minn., U.S.A. Eng. Pat. 114,105, Aug. 27, 1917. (Appl. No. 12,265 of 1917.)

THE copper is heated until it becomes luminous and plunged into a bath containing either 60%

of nitric acid and 40% of vegetable alkali (or caustic potash) by weight, or 75% of nitric acid and 25% of alkali.—T. H. B.

Copper; Treatment of — for various purposes. W. T. Howard, Assignor to L. V. Howard, Baltimore, Md. U.S. Pat. 1,257,943, Feb. 26, 1918. Date of appl., June 23, 1915.

COPPER in a finely divided state, obtained by precipitation from a solution of a copper salt by means of fine-grained iron, is washed, and compressed sufficiently to give a mechanical interlocking union between the particles. The product has a lower specific gravity than cast or rolled copper, is soft and highly porous, has a high conductivity for heat and electricity, and marks paper.—T. H. B.

Metals; Heat treatment of — and apparatus employed therein. Woodward, Gatty, Saunt, and Co., Ltd., London, and O. Stott, Birmingham. Eng. Pat. 114,217, Apr. 10, 1917. (Appl. No. 4975 of 1917.)

A CHAMBER is divided into a series of superposed compartments to receive the metals to be heat treated, and between successive compartments are intermediate heating spaces. Air, gas, or vapour, or a mixture of these, is supplied to the heating spaces and is circulated through the chamber, passing into the compartments containing the metal through perforations in the roofs and floors. Gradual and uniform heating of the metal is thus effected. The atmosphere within the chamber may be maintained at a pressure slightly below that of the atmosphere.

—T. H. B.

Refractory metals [tungsten and molybdenum]; Method of working —. Westinghouse Metal Filament Lamp Co., Ltd., Westminster. From Westinghouse Lamp Co., Bloomfield, N.J., U.S.A. Eng. Pat. 114,282, Nov. 19, 1917. (Appl. No. 17,045 of 1917.)

WIRES of tungsten and molybdenum or other refractory metals are produced by alternate mechanical working and heat treatment of the metal. The mechanical working is carried out at approximately a red heat, and the heat treatment at a higher temperature, e.g., above 1000° C.

—T. H. B.

Hot-blast stoves used in connection with blast-furnaces. W. J. Mellersh-Jackson, London. From C. M. Stein et Cie., Paris. Eng. Pat. 114,333, Mar. 24, 1917. (Appl. No. 4292 of 1917.)

BEFORE combustion in a Cowper, Whitwell, or other hot-blast stove, the air or gas, or both, are passed through a continuous regenerating stove heated by waste gases. (Reference is directed in pursuance of Sect. 7, Sub-section 4, of the Patents and Designs Act, 1907, to Eng. Pats. 4536 of 1881 and 10,204 of 1887.)—T. H. B.

Quicksilver [mercury] ores; Continuous retort for treating —. W. H. Landers, New Almaden, Cal., Assignor to Pacific Foundry Co., San Francisco. U.S. Pat. 1,256,703, Feb. 19, 1918. Date of appl., Apr. 16, 1917.

A METAL retort is enclosed within a body of masonry provided with a series of fire-boxes, each fire-box being connected with a number of fire-brick flues, the walls of which surround the retort. The material is moved continuously through the retort by a conveyor.—T. H. B.

Aluminium; Process of metal-plating —. W. J. Travers, Buffalo, N.Y. U.S. Pat. 1,256,954, Feb. 19, 1918. Date of appl., June 8, 1915.

THE aluminium is cleaned electrolytically by using it as cathode in an alkaline solution, then plated in an electrolyte containing salts of a metal

of the iron group (e.g., a solution of nickel ammonium sulphate acidulated with boric acid), dried, and heated gradually to at least 240° C. to produce an adherence of the electro-plated metal with the aluminium.—T. H. B.

Alloy; High-speed-cutting-tool —. G. L. Kelley, Germantown, and A. H. Miller, Ambler, Pa., Assignors to The Midvale Steel Co., Philadelphia, Pa. U.S. Pat. 1,258,227, Mar. 5, 1918. Date of appl., June 26, 1917.

AN alloy containing a preponderating amount of nickel, with not less than 0.05%, preferably 0.5–2%, of zirconium and a quantity of silicon and aluminium, e.g., 2 to 16%, together equal to at least double the amount of the zirconium.—T. H. B.

Magnesium; [Electrolytic] production of —. G. O. Seward, Jersey City, N.J., Assignor to American Magnesium Corporation. U.S. Pat. 1,258,261, Mar. 5, 1918. Date of appl., July 3, 1915.

AN alloy of magnesium and tin, or magnesium and copper, is produced by electrolysis a suitable electrolyte containing magnesium, using molten tin or copper cathodes, with respect to which magnesium is more electropositive than it is with respect to aluminium. The magnesium is subsequently dissolved out of the alloy by using it as an anode with a suitable molten electrolyte, and depositing the magnesium at the cathode.—B. N.

Alkali metals; Process and apparatus for producing — [by electrolysis]. J. Brode, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen, Germany. U.S. Pat. 1,258,529, Mar. 5, 1918. Date of appl., July 3, 1915.

A FUSED alkali halide is electrolysed, and the alkali metal formed at the cathode is separated from the halogen evolved at the anode by a metallic partition in the form of a hood having a closed top above the cathodes, and a perforated base located opposite the anodes. During the electrolysis the partition is completely covered by the molten electrolyte. The alkali metal formed is drawn off from the cathode space and the halogen evolved in the anode space is drawn off under a reduced pressure.—B. N.

Steel smelting furnaces; Gas valves for —. Z. Davies, Llanelly. Eng. Pat. 114,589, Nov. 7, 1917. (Appl. No. 16,273 of 1917.)

Casting metals and other substances in moulds; Process and apparatus for —. E. Straus, Munich, Germany. Eng. Pat. 108,154, June 2, 1917. (Appl. No. 7951 of 1917.) Under Int. Conv., July 15, 1916.

[Ore] concentrating or slimes tables. M. H. Baker, Bendigo, Victoria, Australia. Eng. Pat. 114,594, Nov. 27, 1917. (Appl. No. 17,536 of 1917.)

Speller; Condensers for redistilling —. J. G. Granberg, Beckemeyer, Ill., U.S.A. Eng. Pat. 112,008, Sep. 18, 1917. (Appl. No. 13,405 of 1917.) Under Int. Conv., Dec. 8, 1916.

SEE U.S. Pat. 1,221,045 of 1917; this J., 1917, 556.

Sulphide ores; Separation of mixed — [by flotation]. C. Faul, St. Kilda, and H. Lavers, Surrey Hills, Victoria, Australia, Assignors to Minerals Separation North American Corporation. U.S. Pat. 1,257,990, Mar. 5, 1918. Date of appl., June 26, 1916.

SEE Eng. Pat. 2974 of 1915; this J., 1916, 605.

Aluminium; Production of —. G. Giuliani, Lazzago, Italy. U.S. Pat. 1,257,995, Mar. 5, 1918. Date of appl., Apr. 29, 1913.

XII.—FATS; OILS; WAXES.

Castor oil: Determination of the purity of —. Chercheffsky. Ann. Chim. Analyt., 1918, 23, 75—81.

THE method proposed depends on the critical temperature of solution of the oil in ethyl alcohol (sp. gr. 0.8181 at 15° C.). Ten drops of the oil and 40 drops of the alcohol are placed in a tube

10 cm. in length and 6 to 8 cm. in diameter, and the open end of the tube is then sealed hermetically. The tube is placed in an oil or glycerol bath and the temperature of the latter is raised gradually until the curved meniscus between the oil and alcohol layers becomes flat and horizontal. The contents of the tube are now mixed without removing the tube from the bath, and this is allowed to cool slowly. The temperature at which the mixture becomes permanently turbid is noted. In the case of pure castor oil this point lies between 66° and 67° C.; with other oils it is much higher, namely, rape oil, 202°, earlnut (arachis) oil, 197°, cottonseed oil, 172°, linseed oil, 163°, and fish oil, 167° C. The presence of 2% of any of these oils in castor oil raises the turbidity temperature of the latter to 69°—71° C. The author criticises the method described by Frabot (this J., 1918, 98 A), mainly on the difficulty of obtaining petroleum spirit of uniform composition for use in the test.—W. P. S.

Analysis of cholesterol [compounds]. Lifschütz. See XX.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Pigments; The tinting strength of —. T. R. Briggs. J. Phys. Chem., 1918, 22, 216—230.

THE power of one pigment to impart its colour to a mixture containing a second pigment is greatly increased if the first pigment coats over and hides the particles of the second one; the smaller the particles of the first are, relatively to the second, the less of the former is required to coat the particles, and consequently the greater becomes the tinting strength of the first pigment. Anything which favours the adhesion of the fine to the coarse particles promotes the coating-over effect, and increases the tinting strength of the first pigment, whilst with particles of the same size and with equal adhesive power to promote the coating tendency, the greater the hiding power the higher is the tinting strength. With proper control of the other factors it is stated that it ought to be possible to estimate hiding power from tinting strength, if the pigment to be tested is very fine compared with the one with which it is mixed, and if it actually coats over and hides it. Other physical properties, besides colour, of mixed powders are dependent very largely upon relative size of particles and the coating-over effect; thus the relative size has an important bearing on the colour of a mixture of two pigments one of which is inert. The coarser the inert pigment is, the larger is the amount which may be added without appreciably affecting the shade of the mixture. This accounts for the fact that ground barytes, silic, and asbestine are used so generally as inert fillers, as each substance consists of particles far larger than those of the majority of the pigments with which they are mixed.—B. N.

Covering power of pigments with special reference to photographic prints. Renwick. See XXI.

PATENTS.

Sulphide of zinc; Preparation of anhydrous —. P. Comment, Dijon, France. Eng. Pat. 106,489, May 8, 1917. (Appl. No. 6551 of 1917.) Under Int. Conv., May 16, 1916.

DEHYDRATED, finely powdered zinc sulphate is intimately mixed with sodium sulphate (or potassium sulphate, or a mixture of both) and zinc persulphide in the proportions corresponding to the equation:— $2 \text{ZnSO}_4 + \text{ZnS}_2 + 2 \text{Na}_2\text{SO}_4 = 3 \text{ZnS} + 2 \text{Na}_2\text{S}_2\text{O}_4 + 4 \text{SO}_2$. The mixture is

calcined at about 800° C., protected from the air, until decomposition of the zinc persulphide is complete, the zinc sulphide washed free of alkali sulphate and dried at 100° to 120° C. The quantity of alkali sulphate may be reduced in proportion to the degree of fineness and the intimacy of the mixture. Instead of anhydrous zinc sulphate, an anhydrous alkali-zinc sulphate may be used, or, during evaporation of a solution of zinc sulphate, sufficient alkali pentasulphide may be added for the formation of the necessary quantity of zinc persulphide. The zinc sulphide obtained is suitable for use in painting.—L. A. C.

Resins: Method of manufacturing permanently fusible and soluble — from non-fusible phenol-aldehyde resins. L. Berend, Amöneburg, Germany. U.S. Pat. 1,259,347, Mar. 12, 1918. Date of appl., June 28, 1915.

SEE Eng. Pat. 107,205 of 1916; this J., 1917. 969.

XV.—LEATHER; BONE; HORN; GLUE.

Glucose [dextrose]; New galloyl derivatives of — and comparison with chebulic acid. E. Fischer and M. Bergmann, Ber., 1918, 51, 298—320.

PARTIALLY acylated glucoses may be obtained by the action of acyl chlorides on the acetone condensation products of dextrose in the presence of quinoline or pyridine, the isopropylidene group being removed subsequently by hydrolysis with acids. A trigalloylglucose has now been prepared, starting with glucosemonoacetone, and a galloylglucose from glucosediacetone. The former is a tannin-like mass, but the latter does not show the typical behaviour of tannins towards gelatin and alkaloids.

Chebulic acid, the eutannin of commerce, is a gallic acid derivative which yields dextrose on hydrolysis. Compared with trigalloylglucose, however, the rate of hydrolysis is slow, and for this and other reasons the conclusion is drawn that chebulic acid is not structurally similar to trigalloylglucose. (See further J. Chem. Soc., 1918, i., 224.)—J. C. W.

Proteins [gelatin]; Ionisation of — and antagonistic salt action. J. Loeb, J. Biol. Chem., 1918, 33, 531—549.

WHEN powdered gelatin is soaked in a sodium chloride solution of M/8 or M/4 strength, imbibition occurs to a certain extent. If now the gelatin is washed with water, or a weaker solution of a neutral salt of a univalent metal, a large additional swelling of the gelatin takes place. With a weak solution of a salt with a divalent cation (such as calcium) contraction instead of additional swelling occurs. The author explains the observed phenomena by the assumption that the additional swelling is due to ionisation and that a salt with a univalent metal forms an ionisable compound with gelatin, whilst a salt with a divalent metal forms a non-ionisable compound. Antagonistic salt action is due to the transformation of an ionisable into a non-ionisable protein compound. (See also J. Chem. Soc., 1918, i., 240.)—H. W. B.

Gelatin: Effects of electrolytes on — and their biological significance. II. Effect of salts on the precipitation of acid- and alkali-gelatin by alcohol. Antagonism. W. O. Fenn, J. Biol. Chem., 1918, 33, 439—451.

THE hindering action of acids and alkalis on the precipitation of gelatin by alcohol (see this J., 1918, 216 A) is reduced when univalent salts like sodium chloride are also present in the gelatin solution. Divalent cations (like calcium) are

antagonistic to alkalis, but not to acids, whilst divalent anions (like sulphate) have the reverse effect. (See also J. Chem. Soc., 1918, i., 240.)
—H. W. B.

PATENT.

Leather: Process of manufacturing —. A. Barclay, Prahran, Victoria, Australia. Eng. Pat. 114,358, May 4, 1917. (Appl. No. 6391 of 1917.)

DE-HAIRED and bated skins are immersed for 30 mins. to 8 hours, according to their size, in a mixture consisting of saturated magnesium sulphate solution, 1, and water, 2 parts, formalin being added in the proportion of 0.5 oz. per gall. of the mixture. The skins are then drained and tanned.—W. P. S.

XVI.—SOILS; FERTILISERS.

Boron; Its effects on crops and its distribution in plants and soils in various parts of the United States. F. C. Cook and J. B. Wilson. Proc. Amer. Soc. Biol. Chem., Dec., 1917, vi.—vii. J. Biol. Chem., Mar., 1918.

THE authors describe the effects of manure to which a proportion of borax or colemanite (calcium borate) has been added, on various crops grown in different parts of the United States (see this J., 1915, 675; 1916, 319; 1917, 1186). The conclusion drawn is that the absorption by and the toxic effect of boron on plants varies with the variety of plants, the solubility of the boron compound, the amount of the boron compound added to the soil, the time elapsing after the compound is mixed with the soil before planting, the amount of rainfall, etc., and finally, with the character of the soil to which the boron compound is added. Thus, in some soils, 0.0044% boric acid added as borax and 0.0058% added as colemanite had no injurious action on lettuce, spinach, and kale, whilst at another spot 5 miles distant, similar percentages in the soil resulted in a distinct diminution in the crops of these vegetables. Wheat, oats, and rye absorbed only a little boron, whilst leguminous and succulent plants absorbed comparatively large amounts and were adversely affected by relatively small traces of the boron compounds in the soil.—H. W. B.

Heat; Effect of sodium nitrate applied at different stages of growth on the yield, composition, and quality of —. J. Davidson and J. A. Le Clerc. J. Amer. Soc. Agron., 1917, 9, 145—154. Bull. Agric. Intell., 1917, 9, 180—181.

EXPERIMENTAL plots of wheat were treated at different stages with sodium nitrate either in solution or in the solid state, at the rate of 320 lb. per acre. Applied at the early stages of growth, when the plants were about 2 ins. high, the nitrate stimulated vegetative growth and increased the yield. Applied at the time of "heading," it improved the quality of the grain as regards colour and protein-content, without affecting the vegetative growth. Application at the "milk stage" had no effect on the yield, quality, or protein-content of the grain. The same results were obtained whether the nitrate was applied in the solid state or in solution, except in the case of early application, the solution then giving higher yields than the solid, no doubt owing to better distribution in the soil. The experiments confirmed the inverse relation between nitrogen-content and yellow colour of the grain: potassium chloride alone appears to increase this colour, but does not affect either the vegetative growth or the chemical composition of the grain.—J. H. L.

Oats; Effect of fertilisers on the protein-content of —. R. W. Thatcher and A. C. Army. J. Amer. Soc. Agron., 1917, 9, 344—348. Bull. Agric. Intell., 1918, 9, 153—156.

FIELD experiments at the Minnesota Agric. Exp. Station, with oats grown in a 3-year rotation of oats, clover, and maize, indicated that nitrogenous fertilisers, and especially sodium nitrate, increase the protein-content of the grain. Potassium chloride appears to have a slight effect in the opposite sense, whilst phosphate fertilisers do not materially affect the nitrogen-content. The average protein-contents of the oats (dry substance) corresponding to the different fertiliser treatments, ranged from 13.4% with potassium chloride, to 15.24% with a "complete" commercial fertiliser. —J. H. L.

Fertilisers; Production of —. P. Becquevort. London. Eng. Pat. 114,277, Oct. 30, 1917. (Appl. No. 15,812 of 1917.)

THE calcium carbonate occurring in natural phosphates is converted into calcium chloro-ferrite, $\text{CaCl}_2 \cdot \text{CaO} \cdot \text{Fe}_2\text{O}_3$, which is not attacked by the acids present in soils. The phosphate is ground and for every 100 parts of calcium carbonate present there are added 111 parts of calcium chloride and 160 parts of ferric oxide; the mixture is formed into briquettes, then heated at 1000°C ., cooled, and ground.—W. P. S.

Phosphatic and nitrogenous fertiliser; Process of making a mixed —. R. F. Gardiner. Clarendon, Va. U.S. Pat. 1,258,106, Mar. 5, 1918. Date of appl., Aug. 6, 1917. Dedicated to the public.

APATITE is ground to pass any mesh between 60 and 200, then heated at about 900°C . and fused with ammonium sulphate and its dissociation products.—W. P. S.

XVII.—SUGARS; STARCHES; GUMS.

Cane sugar; The deterioration of raw —: A problem in food conservation. C. A. Browne. J. Ind. Eng. Chem., 1918, 10, 178—190.

THE deterioration of raw and semi-refined cane sugars during storage, under the action of micro-organisms, has been recognised to depend on the relation between the moisture and the non-sucrose present in the sample. This relation has been formulated by the Colonial Sugar Refining Co. of Australia, according to the rule that in sugar intended for storage the percentage of moisture must not exceed half that of the non-sucrose. In other words, if W = the moisture and S the sucrose, the "factor of safety" $\frac{W}{100-S}$ must not exceed 0.333. The author confirms the general validity of this rule, with the modification that for sugars of the Cuban and Porto Rican type, the factor of safety must not exceed 0.30. In cold weather, if the temperature does not exceed 20°C ., no deterioration will take place, but it will start again when the warm season sets in. Sugar deteriorating in warehouse may lose moisture simultaneously with sucrose, and the action may be concealed for this reason. Cases in which the sugars deteriorate in spite of a low factor of safety are most frequently explainable by an uneven distribution of the moisture, either by the mixing of

different batches or by migration of moisture due to sweating. The danger of bagging sugar direct from the centrifugals has long been recognised. Certain corollaries follow from the "factor of safety" rule. For instance, slight fluctuations in moisture content will have a far greater influence on high-grade sugars than on low-grade products. This is confirmed by practical experience in the storage of high-grade raw sugars and moist refined sugars; it has even been found advantageous to wash the sugars in the centrifugals with molasses instead of with water. In the case of samples stored in closed bottles, the factor $\frac{W}{100-S}$ will fall

as deterioration proceeds, until a limit is reached where the sugar is stable. In such cases it has been found that the limit factor is nearer 0.25 than 0.3, owing to a residual inverting power after multiplication of the organisms has ceased. Thus a sugar which has been in active deterioration soon after manufacture may arrive at its destination with a safety factor below 0.3, but still be liable to further deterioration. In over 90% of the cases investigated, deterioration follows the normal course, in which polarisation and sucrose diminish and invert sugar increases until the limit of deterioration is reached, the percentage of moisture remaining practically constant. Abnormal fermentations, however, are met with; in some cases there is an increase in polarisation, which is explained by the fermentation of levulose, this being shown by abnormal Clerget values for sucrose, lower than the direct polarisation. In such cases, also, an increase in moisture or other volatile matter is frequently observed. In deterioration in closed bottles an odour of alcohols and esters is usually perceptible; the principal product of the fermentation is carbon dioxide. Cases are on record of spontaneous combustion of sugar cargoes under certain imperfectly understood conditions. The author has made a bacteriological study of the micro-organisms found in raw cane sugars; some of these are harmless towards sucrose, others are destructive. The destruction of sucrose in deteriorated sugar is not due to any single organism or class of organisms; moulds and budding fungi are to be looked for, as well as bacteria. The organisms which cause the inversion of sucrose in raw sugars are unable to thrive in saturated solutions; the washing of raw sugars in the centrifugals, by diluting the films of saturated syrup to a point where inverting organisms can thrive, must be regarded as a leading cause of deterioration. One of the most fertile sources of infection is the water coming from the cooling tower, employed for cooling the warm condensation waters from the factory. This water frequently contains sugar and is highly favourable to the growth of micro-organisms. The use of this water in the centrifugals or the access of spray from the cooling tower to the sugar warehouse is certain to cause trouble. To prevent the deterioration of sugar, methodical care and cleanliness in manufacture and storage, systematic drying of the manufactured sugar, clean and dry warehouses with good ventilation in dry weather and exclusion of moisture in wet weather, are the principal points for attention.—J. F. B.

Sugar reagents; Copper-phosphate mixtures as —. A qualitative test and a quantitative titration method for sugar [dextrose] in urine. O. Folin and W. S. McElroy. J. Biol. Chem., 1918, 33, 513—519.

THE quantitative reagents proposed for the estimation of dextrose in urine are a solution containing 60 grms. of crystallised copper sulphate and 4 c.c. of concentrated sulphuric acid per litre, and a dry mixture containing 100 grms. of

crystallised disodium hydrogenphosphate, 60 grms. of dry sodium carbonate, and 30 grms. of sodium or potassium thiocyanate. To carry out an estimation, 5 c.c. of the copper solution and 4 to 5 grms. of the powder are boiled in a test-tube and the urine run in, a few drops at a time, from a burette with a capillary tube attached, until the solution is colourless. 5 c.c. of the copper solution is equivalent to 25 mgrms. of dextrose (also to 45 mgrms. of anhydrous maltose or 40.4 mgrms. of anhydrous lactose). (See also p. 278 A, and J. Chem. Soc., May, 1918.)—H. W. B.

Sugar; Note on Cammidge's method for the estimation of [reducing]— R. W. Garrow. Pharm. J., 1918, 100, 148.

CAMMIDGE has described a modification of Scales' method (this J., 1915, 1264) for the volumetric determination of cupric-reducing sugars in urine, blood, and other physiological liquids. Instead of Fehling's solution, a modified Benedict solution is employed, containing 200 grms. of sodium citrate, 100 of dry sodium carbonate, 10 of sodium bicarbonate, and 21 of crystallised copper sulphate in 1000 c.c. After the reduction, hydrochloric acid is added to dissolve the cuprous oxide; carbon dioxide is thus liberated and protects the cuprous chloride against atmospheric oxidation. The cuprous chloride is added to a known excess of standard iodine solution and the excess of iodine is titrated back with thiosulphate. Each c.c. of *N*/10 iodine is equivalent to 0.0033 gm. of dextrose. Up to the point when the blue iodo-starch colour is discharged, the solution is perfectly transparent, but immediately after the first end-point is reached a slight opalescence begins to appear, increasing to a white precipitate of cuprous iodide, and the blue colour returns. The first discharge of the blue colour should therefore be taken as the end-point, and the titration should be done as rapidly as possible.

—J. F. B.

Honey; The ash test for — H. Stout. Pharm. J., 1918, 100, 147.

THE specification for honey in the British Pharmacopoeia of 1914 reads:—"Ash not more than 0.25%; solution of the ash in water is not alkaline to litmus." In Squires' "Companion to the B.P." (1916), it is pointed out that the requirement of a non-alkaline ash is evidently an error and is likely to exclude genuine honey while favouring an article prepared with starch or invert sugar. This view is confirmed by the author, who has examined several samples of honey of Cuban, Californian, Irish, and Scotch origin, showing ash contents of 0.1–0.14%, and the solutions of the ash in all cases were alkaline to litmus.—J. F. B.

XVIII.—FERMENTATION INDUSTRIES.

Beverages; Non-alcoholic carbonated —: sanitary condition and composition. R. M. Allen, J. O. La Bach, W. R. Pinnell, and L. A. Brown. Kentucky Agric. Exp. Stat., Bull. No. 192, June, 1915. Pp. 65.

A REPORT on the inspection of about 70 factories producing non-alcoholic beverages, with the results of chemical and bacteriological examination of the raw materials and products. Bacterial counts of the waters used and of the bottled beverages, showed that carbonation greatly reduces the number of bacteria, but is not of itself sufficient protection against contaminated water or insanitary conditions of manufacture. The chief sources of infection were the waters used, and the

bottles, the latter having in many cases been very imperfectly cleansed before use. For the detection of bacteria of the *B. coli* group direct plating on Endo fuchsin medium (nutrient agar with lactose, fuchsin, and sodium sulphite added when ready for use) was found a very trustworthy presumptive test, the plates being incubated for 24 hours at 37° C.: the only disadvantage is that considerable care and experience is required in the preparation of the medium to obtain uniform results. Most of the beverages investigated consisted of carbonated water sweetened, flavoured, and coloured in imitation of a fruit. For the flavour of strawberry, raspberry, banana, and pineapple, mixtures of synthetic esters are invariably used, and as the true extracts of lemon, lime, and orange are only slightly soluble in water, terpeneless extracts and imitation flavours are largely used in these cases also. Owing to the slight solubility of oil of ginger, ginger ales are generally fortified with capsicum, which gives the desired pungency and is cheaper. A few non-alcoholic beverages contain actual grape juice, apple juice, or other fruit juice, but in most cases synthetic flavouring matters are used. Those having a vanilla flavour usually contain synthetic vanillin and coumarin. Caffeine is a constituent of another class of beverages, e.g., those of the cola type, made from certain vegetable extracts diluted with carbonated water; in 25 products of this class the proportion of caffeine ranged from 0.012 to 0.268 gm. per 100 c.c., which is considerably less than that present in tea or coffee. Beverages of this class have usually a naturally dark colour; ginger ales, root beers, etc., are coloured with caramel, whilst aniline dyes are generally employed for the beverages of brighter colours. Saccharin and benzoic acid were found in a number of the products and saponin in one of the concentrated foaming ingredients.—J. H. L.

Wines; Methods for determining the adulteration of — U. Pratolongo. Staz. Sper. Agrar. Ital., 1917, 1, 315–364. Bull. Agric. Intell., 1918, 9, 109–111.

VARIOUS empirical rules have been suggested, by Gauthier, Halphen, Blarez, Roos, and others, for discriminating between natural and adulterated wines, on the basis of the relation between alcohol-content and acidity. A study of the analytical data for 560 Italian wines showed that all these rules are subject to numerous exceptions. That of Blarez appears to be the most useful, and is recommended in a modified form for the detection of adulteration. For this purpose the author divides natural Italian wines into two categories, viz., those of "normal" and those of "abnormal" composition, and gives for each a table showing the minimum permissible acidity for various alcohol-contents. He proposes that wines of the second category (which constituted about 10 % of the total number of wines studied) should be sold only with a declaration of origin which would justify their "abnormal" composition. All wines sold without such a declaration should be regarded as adulterated unless conforming with the table for those of "normal" composition.—J. H. L.

Wines; Presence of copper in white — P. Carles. Ann. Falsif., 1918, 11, 43–48.

THE presence of traces of copper (equivalent to 0.015 gm. of crystallised copper sulphate per litre) has been detected in certain white wines. These wines gradually become turbid when bottled, but the turbidity disappears if the wine is kept in an uncorked bottle for some time; it reappears when the bottle is again corked. If the turbid wine is centrifuged, a red sediment of cuprous oxide is obtained.—W. P. S.

Cider; Contribution to the study of the alcohols of —. E. Kayser. Bull. Soc. Agric. de France, 1917, 321—323. Bull. Agric. Intell., 1918, 9, 239—241. (See also this J., 1917, 608, 902.)

THREE portions of sterilised apple must were sprinkled with a strong yeast and an apiculated cider yeast and allowed to ferment for three and a half months at 4°—12° C. One portion was then decanted from the yeast deposit into a second sterile flask, the second was similarly decanted into a flask containing another yeast which had already fermented similar must, whilst the third was left undisturbed. After a further period of 2½ months (March—June) the ciders and the alcoholic distillates therefrom were analysed. The results showed that decantation before the secondary fermentation increased the production of aldehydes and higher alcohols, probably owing to aeration. The quantity of higher alcohols plus esters was greatest in the cider which had been decanted on to a new yeast, whilst the volatile acidity was highest in the sample which had been decanted into a clean flask. Although the particular kind of yeast employed is probably a very important factor, the results show that cider for drinking and cider for distilling require different treatment.—J. H. L.

Horse-chestnuts; Use of — for the production of alcohol. Kayser. Feuille d'Inform. du Minist. de l'Agric., (France), 1917, 22, 10. Bull. Agric. Intell., 1918, 9, 111—112.

FERMENTATION experiments indicated that 100 kilos. of dry horse-chestnuts (value 12s. 8d. in France) will yield 27—28 litres of alcohol, which, though lower than the yield obtainable from maize, would warrant their industrial use under present conditions (cp. this J., Goris, 1917, 1107; Baker and Hulton, 1917, 1285). They contain about 0.5% of potassium and 0.15% of phosphoric acid, both of which are indispensable yeast foods. —J. H. L.

Acorns; Utilisation of — by alcoholic fermentation. Kayser. Feuille d'Inform. du Minist. de l'Agric. (France), 1917, 22, 9—10. Bull. Agric. Intell., 1918, 9, 112.

ACORNS from three varieties of oak (pedunculate, sessile, and holm) found in the Mediterranean district, were freed from their cups, cut into small pieces and heated at 120°—122° C. for half an hour with 2—3 times their weight of water containing 2.5% of hydrochloric or 1% of sulphuric acid. The residual solid matter was separated from the liquid and completely exhausted by crushing and washing with hot water; and the extract, after partial neutralisation with potash, was seeded with grain yeast or cider yeast. Fermentation commenced in 24 hours, or sooner after addition of 1—2 parts per thousand of sweet rye extract. Dilution of the liquid also accelerated fermentation, owing to the fact that acorns contain considerable amounts of tannin which retards fermentation. The yield of alcohol varied, according to the variety of plant, the degree of ripeness, and, above all, the dilution of the extract, from 8.58 to 20.16 litres per 100 kilos. of whole acorns (dried), or from 28 to 31 litres per 100 kilos. of dried kernels. (See also Baker and Hulton, this J., 1917, 1285.)—J. H. L.

Yeast manufacture; The amino nitrogen in pressed —. K. Schweizer. Schweiz. Chem.-Zeit., 1918, 2, 26—28.

SOERENSEN'S formaldehyde titration method (this J., 1908, 135) may be usefully applied in the analysis of the mashers for the manufacture of pressed yeast by the aeration process. Ten c.c. of filtered mash or sweet wort is neutralised with N/10 sodium hydroxide to a standard pink in

presence of 6 drops of 1% phenolphthalein solution; 5 c.c. of commercial formaldehyde, similarly neutralised, is added, and the acidity of the amino-acids then determined by titration. Results of several determinations of amino-acids in pure grain mash and part grain, part molasses mash would appear to indicate that the concentration of amino nitrogen approximates to an equilibrium, corresponding to about 0.018%, irrespective of the quantity of total nitrogen present during the mashing process. Determinations of the amino-acids, total acidity, and density of the worts showed that a good proteolysis does not necessarily correspond with a good acidification and saccharification. Soerensen's titration method is also applicable to the so-called mineralised worts to which nitrogen is added in the form of ammonium salts. The titration of ammonium sulphate may be made with sufficient accuracy between the limits of 0.5—5.0% concentration.

—J. F. B.

Yeast-nucleic acid; Preparation of —. E. J. Baumann. Proc. Amer. Soc. Biol. Chem., Dec., 1917, xiv—xv. J. Biol. Chem., March, 1918.

FRESH brewer's yeast is diluted with water, and the nucleic acid is obtained from the nucleoprotein by treatment with a concentrated solution of sodium hydroxide (100 grms. of alkali per kilo. of yeast). The proteins are removed by precipitation with acetic acid, after partial neutralisation with hydrochloric acid, and the nucleic acid obtained from the filtrate as the insoluble magnesium salt by the addition of magnesium sulphate and hydrochloric acid. The yield is 4 to 7.5 grms. per kilo. of yeast. (See also J. Chem. Soc., May, 1918.) —H. W. B.

Yeast-nucleic acid; Structure of —. III. Ammonia hydrolysis. P. A. Levene. J. Biol. Chem., 1918, 33, 425—428.

THE occurrence of uridine-phosphoric acid among the products of hydrolysis of yeast-nucleic acid by dilute ammonia at 115° C. confirms the view according to which yeast-nucleic acid is constructed of four mono-nucleotides containing guanine, uracil, cytosine, and adenine respectively. —H. W. B.

Optical method for determination of malic and tartaric acids in the same solution. Willman. See XXIII.

PATENTS.

Evaporating apparatus [for alcohol]. C. R. Harris, Los Angeles, Cal. U.S. Pats. (A) 1,258,562 and (B) 1,258,563, Mar. 5, 1918. Date of appl., May 4, 1917.

(A) AN evaporating apparatus for liquids, e.g., alcohol, comprises an evaporating vessel having a central horizontal perforated diaphragm, and an outlet at its upper end. The outlet conduit consists of a series of tubes oppositely inclined alternately, having their ends connected by short vertical tubes, thus forming a zigzag conduit. The inclined portions are filled with fibrous, porous, or granular material to retain entrained water, the vertical connecting pipes being empty. The water returns to the evaporator by gravity. (B) The evaporating vessel is provided with an inlet and outlet for liquid at its lower end, and in its upper part with radial arms supported centrally and carrying vertical evaporating surfaces. A slightly domed baffle-plate is arranged between the top of the evaporating surfaces and the cover of the vessel, and a zigzag discharge pipe is connected centrally in the cover. The baffle-plate is of greater diameter than the set of evaporating surfaces, so that any condensed liquid falling from the outlet pipe is directed beyond the evaporating surfaces.—W. F. F.

Milk product. U.S. Pat. 1,256,634. See XIXA.

Method of manufacturing grape-juice. U.S. Pat. 1,258,627. See XIXA.

XIXA.—FOODS.

Dried milks; Inquiry as to — with special reference to their use in infant feeding. F. J. H. Coutts. Report to the Local Government Board. Food Reports, No. 24, 1918, 1—137.

THE report deals with the history, methods of preparation, and distribution of dried milk, its physical and chemical characters, its bacteriology, and more particularly its use in infant feeding. It is considered that dried milk is a valuable food and one which possesses certain special advantages; it is easy to transport, keeps for a reasonable period of time without developing an unpleasant flavour, and is economical. Dried milk is not germ-free, but the number of bacteria present is relatively very small as compared with ordinary milk, especially in those varieties of dried milk which have been prepared by passing milk over rollers heated above 100° C.; there is no tendency towards multiplication of the number of bacteria when the milk is kept. The pathogenic bacteria which may have been contained in the original milk are either destroyed or reduced in number and rendered less virulent by the drying process. Dried milk prepared from a mixture of separated milk and an emulsion of some vegetable oil such as cottonseed oil, forms a suitable food for some infants but not for all.—W. P. S.

Dried milk; Some investigations bearing on the nutritive value of —. G. Winfield. Report to the Local Government Board. Food Reports, No. 24, 1918, 139—156.

As a result of comparative feeding tests on infants, it is concluded that cows' milk during the process of desiccation loses none of the characters which are necessary for the support of normal growth in children. Experiments with rats proved that dried milk used as a sole food is capable of maintaining an animal in good health.—W. P. S.

Milk powders; Examination of — at the Government Laboratory. J. J. Dobbie. Report to the Local Government Board. Food Reports, No. 24, 1918, 157—184.

TWENTY-SIX samples of dried milk prepared from whole milk contained:—Moisture, 1.85 to 6.10; fat, 22.58 to 31.23; proteins, 22.27 to 26.50; hydrated lactose, 33.26 to 41.39; ash, 5.44 to 7.58%. Seven of these samples contained sucrose in quantity varying from a trace to 2.94%. Fifty samples prepared from skimmed milk contained from 0.67 to 3.40% of fat, whilst seven other samples examined had been made from partially skimmed or impoverished milk. A few of these samples were described as "half-cream milk powder," but they had been prepared from milk deprived of 56 to 84% of its fat. In some cases the quantity of ash present was higher than the normal amount due to the presence of very small quantities of such added substances as sodium bicarbonate, alkali phosphate, and calcium oxide combined with sugar. There was no evidence of the presence of foreign fats, but two of the powders contained boric acid and five salicylic acid. With the exception of one sample, which contained annatto, all the milk powders were free from artificial colouring matters. Three of the samples contained 0.08, 0.10, and 0.19%, respectively, of dirt, which consisted of sand, sawdust, vegetable fibres, charred organic substance, etc.; only two samples were quite free from insoluble foreign

matter. Minute traces of copper were present in eleven of the samples. Five samples other than dried milk were also examined; these consisted of milk powder sweetened with sucrose (39.7%); milk powder containing added lactose (6.5%); this sample was stated on the label to contain added sodium citrate, but the quantity of citric acid present did not exceed that found in normal milk; lactose (98.4%), and two protein preparations (76.17 and 75.05% of proteins, respectively).—W. P. S.

Milk; Estimation of lactose in —. O. Folin and W. Denis. J. Biol. Chem., 1918, 33, 521—524.

Titration method: By employing the reagent and apparatus described for the estimation of dextrose in urine (see page 275 A), the lactose in milk may be determined without previously removing either the protein or the fat from the milk. It is advisable to dilute the milk 1:4 (25 c.c. in a 100 c.c. flask) for cow's milk and 1:5 (5 c.c. in a 25 c.c. flask) for human milk. The titration is made as follows:—2.8 to 3.4 c.c. of the diluted milk (that is, nearly the full amount expected), 5 c.c. of the copper sulphate solution, 4 to 5 grms. of the dry salt mixture, and a pebble (to prevent bumping) are introduced into a large test-tube, shaken, and boiled gently for 4 minutes. Then a few drops more of the diluted milk are added, and the mixture boiled again, the addition of the diluted milk being continued, boiling for 1 minute after each addition, until the liquid is just colourless. The total boiling period should be 5 to 7 minutes. The volume of diluted milk required to bring about complete decolorisation contains 40.4 mgrms. of lactose.

Colorimetric method: This is a modification of Dehn and Hartman's method (this J., 1914, 271). A 100 c.c. volumetric flask is half filled with saturated picric acid solution and then 2 c.c. (accurately measured) of the milk is added. The volume is brought to 100 c.c. with saturated picric acid solution and the flask is then shaken and the contents filtered. 5 c.c. of the filtrate is transferred to another 100 c.c. flask, 15 c.c. of saturated picric acid solution and 3 c.c. of 20% sodium carbonate solution are added, and the mixture heated in a boiling water bath for 15 minutes. After cooling, the liquid is diluted to 100 c.c. The colour is then compared with a similar solution prepared at the same time from 20 c.c. of a standard 0.025% solution of lactose in saturated picric acid solution and 3 c.c. of sodium carbonate solution, subsequently diluted to 100 c.c. Accurate results are obtained only when the standard and unknown solutions are heated simultaneously and the colour values of the two solutions do not differ by more than 20%. For use with human milk, a second standard containing 0.035% of lactose in saturated picric acid solution is recommended.—H. W. B.

Butyrometers; Graduation and calibration of Gerber new milk —. F. E. Day and M. Grimes. Analyst, 1918, 43, 123—131.

THE volume of a 1% scale division on the tube should be 0.1240 c.c.; the capacity of the body of the tube, from the body end of the scale to the inner end of the neck, should be 20.5 to 21.5 c.c., and the milk pipette should deliver 11 grms. of water at 15° C., equivalent to 11.18 to 11.30 grms. of milk. The correct temperature for reading the volume of the fat in a determination is about 55° C.

—W. P. S.

Condensed milk; Determination of the acidity of —. M. Dugardin. Ann. Chim. Analyt., 1918, 23, 83—84.

TEN grms. of the sample is diluted with 25 c.c. of water free from carbon dioxide and the solution

is titrated with *N*/10 sodium hydroxide solution, using phenolphthalein as indicator. Wholesome condensed milk, whether sweetened, unsweetened, or skimmed, does not contain more than 0.5% of acidity, calculated as lactic acid.—W. P. S.

Wheat flour; Non-protein nitrogen in —. M. J. Blish. *J. Biol. Chem.*, 1918, 33, 551—559.

THE ordinary protein precipitants do not satisfactorily remove gliadin and the other vegetable proteins from an aqueous extract of wheat flour. For the estimation of non-protein nitrogen in flour the author recommends the preparation of an extract obtained by shaking 20 grms. of flour with 400 c.c. of water for 2 hours and then filtering through paper. The proteins are precipitated by treating 100 c.c. of the extract in a 200 c.c. flask with 25 c.c. of *N*/10 sodium hydroxide followed by 27 c.c. of *N*/10 copper sulphate solution, shaking vigorously until the precipitate settles rapidly, making up to the mark, filtering, and estimating the nitrogen in 100 c.c. of the filtrate by Kjeldahl's method. A portion of the filtrate may also be concentrated to 1/20th of its volume and the amino-nitrogen estimated by Van Slyke's method. Wheat flour contains about 0.030% of non-protein nitrogen, of which about 0.002% consists of α -amino-nitrogen and 0.006% of amide-nitrogen. The nature of the remaining 0.022% of non-protein nitrogen has not been determined.—H. W. B.

Flour; The soluble nitrogen as a factor in determining the value of —. E. Rousseaux and M. Sirot. *Ann. Falsif.*, 1918, 11, 38—39.

THE authors have shown previously (this *J.*, 1918, 134A, 163A) that the ratio of total nitrogen to soluble nitrogen in flour affords an indication of the quality of flour for baking purposes; they now propose to use this ratio inversely, i.e., soluble nitrogen to total nitrogen. In the case of normal flour this value will be 0.175, or expressing the total nitrogen as 100, the ratio will be 17.5. For inferior flours the ratio will be more than 19, for maize, 18.1, rye, 22.7, beans, 12.1, barley, 12.1, and rice, 4.27.—W. P. S.

Eggs; Photographic method for the examination of —. G. A. Le Roy. *Ann. Falsif.*, 1918, 11, 10—18.

THE method consists in photographing the eggs directly, whilst illuminated by an arc or ordinary filament lamp. Before the method can be used practically it will be necessary to obtain more data regarding the increase in the volume of the air chamber in eggs on keeping and the effect of temperature, moisture, pressure, etc. on the same. The method appears to be useful for the examination of eggs preserved in cold-store, but would probably be difficult to apply to eggs pickled in sodium silicate, paraffin wax, lime-water, etc.—W. P. S.

Potatoes; Alleged poisoning by —. F. W. Harris and T. Cockburn. *Analyst*, 1918, 43, 133—136.

SIXTY-ONE cases (one fatal) of poisoning occurred recently in Glasgow; all the persons affected had partaken of potatoes obtained from one source. These potatoes had commenced to sprout and contained 0.041% of solanine, which was at least five or six times the quantity found in normal, unsprouted potatoes. This, in conjunction with the medical evidence, proves that the poisoning was caused by the excessive quantity of solanine present in the potatoes.—W. P. S.

Cocoa; Alkalised —. Rocques and Touplain. *Ann. Falsif.*, 1918, 11, 19—26.

ACCORDING to French law the quantity of added alkali in cocoa must not exceed 5.75%, calculated as potassium carbonate and expressed as a percentage of the dry, fat-free material; 2.75% of alkali is taken as being the natural alkalinity of cocoa, so the total alkalinity of an alkalised cocoa must not exceed 8.5%. Of 25 samples of cocoa examined by the authors, 7 contained more than 2.75% of alkali (as potassium carbonate), the largest quantity found being 3.23%, and the suggestion is made that the allowance for the alkali-content of natural cocoa should be increased to, say, 3.50%. French law also requires alkalised cocoa to have a slightly acid reaction, that is, the quantity of alkali added must not be sufficient entirely to neutralise the acidity of the cocoa.

—W. P. S.

Sorghum kernels; Composition of grain —. J. A. Le Clerc and L. H. Bailey. *J. Amer. Soc. Agron.*, 1917, 9, 1—16. *Bull. Agric. Intell.*, 1918, 9, 156—158.

COMPARISON of numerous data relating to six varieties of grain sorghum led to the conclusion that there is no well-defined relation between the thousand-corn weight and the protein-content of the grain. Low protein-content is usually accompanied by high bushel-weight and low contents of fibre, ash, and pentosans. Large corns have often less than the average proportion of fibre, and therefore ash, doubtless because their surface is relatively small in proportion to their volume.

—J. H. L.

Feeding stuffs; Composition of some Indian —. J. N. Sen. *Agric. Research Inst., Pusa, Bull.* No. 70, 1917, 1—60.

TABLES are given showing the composition of feeding stuffs available in India; in many cases, some dozens of analyses of different samples of a material are recorded. The fodders analysed include earthnuts, oats, colza, mustard, rape, pigeon pea, tea seed, safflower, chick-pea, coconut, sunn-hemp, cluster bean, zedoary, yams, horsegram, rocket, buckwheat, soya bean, cottonseed grass, hay, niger seed, sunflower, barley, vetches, lentil, linseed, lucerne, senji, rice, millet, guinea grass, poppy, Burma bean, green gram, field pea, sugar cane, sesamé, clover, wheat, cow pea, maize, ginger, etc.—W. P. S.

Fibrin hydrolysed in the presence of ferric chloride; The nitrogen distribution of —. C. A. Morrow and W. R. Fetzer. *Soil Sci.*, 1918, 5, 163—167.

THE results indicate that when a protein is hydrolysed in the presence of ferric chloride an accurate determination of the nitrogen distribution cannot be effected. Much of the recent work on the organic nitrogen distribution in soils by the Van Slyke method is thus quite unreliable. (See also *J. Chem. Soc.*, 1918, i., 218.)—W. G.

XIXB.—WATER PURIFICATION; SANITATION.

Carbon dioxide; Gasometric determination of combined —. W. Mestrezat. Ann. Chim. Analyt., 1918, 23, 45—47.

CARBONATES in a solution also containing hypochlorites (e.g. alkaline hypochlorite antiseptics) may be determined in an ordinary calcimeter if a tube containing a plug of cotton wool soaked in oil of turpentine is inserted between the reaction flask and the gas measuring burette. The chlorine liberated when the acid is added is absorbed by the turpentine whilst the carbon dioxide passes over into the burette.—W. P. S.

Nicotine-paraffin emulsion. A. H. Lees. J. Bd. Agric., 1918, 24, 1411—1417.

AN insecticide containing soft soap, 20, nicotine, 0.5 lb., paraffin, 2, and water, 100 gall., was found to be very effective against capsids, cabbage caterpillars, gooseberry sawfly (larvæ), raspberry and loganberry beetle (*Byturus tomentosus*), and aphides. The mixture may be given fungicidal properties by adding to it liver of sulphur, sodium sulphide, or ammonium sulphide (see Barker and Lees, J. Bd. Agric., Mar., 1916) but not lime-sulphur, Bordeaux, or Burgundy mixtures, since these latter combine with the soap. As nicotine sulphate is not volatile, it should not be used in place of nicotine in preparing the mixture.—W. P. S.

Insect eggs; Toxicity of volatile organic compounds to —. W. Moore and S. A. Graham. J. Agric. Res., 1918, 12, 579—587.

POTATO-BEETLE eggs were used for the experiments, clusters of 20—30 eggs being treated as a unit. The effects of a large number of compounds were studied by dipping the eggs therein for periods of 1—120 sec.; by spraying the eggs by means of an atomiser; and by fumigating the eggs for 15 hrs. with varying amounts of the compounds, and then in each case exposing them to the air till hatched or proved dead. It was found that slightly volatile compounds with high boiling points, such as trimethylene cyanide, nicotine, nitrobenzene, were more effective in dipping and spraying the eggs than compounds with high volatility and low boiling points, such as ether, alcohol, benzene. The latter compounds killed recently-laid eggs more easily than eggs in which the embryo was partially or fully developed, whereas the reverse was the case with the compounds of high boiling point. Kerosene was toxic to both

formation of sodium acetate: $C_2H_5OH + NaOH = CH_3CO_2Na + 2H_2$. The acetate begins to decompose at the lower temperature mentioned, and the velocity of this secondary change increases so rapidly with the temperature that at $450^\circ C$. the acetate is decomposed almost as quickly as it is formed: $CH_3CO_2Na + NaOH = Na_2CO_3 + CH_4$. Aldehyde tars, ethylene, and water are formed as by-products, but the proportion of these is small. The same reaction occurs when the alcohol is passed over heated caustic soda, but lime has very little effect. It is supposed that the caustic soda acts as a catalyst, and that the first stage in the reaction is the formation of acetaldehyde, which then decomposes further. In support of this view, it has been found that sodium acetate is also formed when acetaldehyde vapour is passed over heated soda-lime. (See also J. Chem. Soc., 1918, i., 211.)—H. M. D.

Acetone and lime. M. E. Freudenheim. J. Phys. Chem., 1918, 22, 181—193.

WHEN acetone is passed over slaked lime heated to temperatures varying from 350° to $630^\circ C$., methane, hydrogen, carbon monoxide, ethylene, and carbon dioxide are produced. The percentages of methane, carbon monoxide, and ethylene, calculated on the total gas evolved, rise from 10%, 0%, and 1% respectively at $350^\circ C$. to 54%, 23%, and 5% at $630^\circ C$., whilst the hydrogen falls from 78% at $350^\circ C$. to 10% at $630^\circ C$. The rate of evolution of the gas increases from 5 c.c. at $350^\circ C$. to 170 c.c. per minute at $630^\circ C$.; very little carbon is deposited in the heated tube at lower temperatures, but the amount rapidly increases at higher temperatures. It is stated that acetone may be an intermediate product when calcium acetate and lime are heated together. The production of methane and hydrogen only at $350^\circ C$. has not been satisfactorily explained, but it is noted that sodium acetate and soda-lime when heated together yield hydrogen in addition to methane. The formation at higher temperatures of the gases enumerated is accounted for by the possible production of keten, CH_3CO , and the dissociation of acetone and keten separately into methane, hydrogen, carbon monoxide, and ethylene. (See also J. Chem. Soc., June, 1918.)—B. N.

Antimony; The chemotherapeutics of —. M. Tsuzuki. Schweiz. Chem.-Zeit., 1918, 2, 17—22, 36—40.

JUST as quinquevalent arsenic compounds, though far less poisonous than the trivalent derivatives, are without therapeutic value, so quinquevalent antimony compounds have been found to be similarly inert; in fact a biological method has been proposed for determining the valency of antimony in its compounds in this way, although a few exceptions to the rule exist. An outstanding difference between the trivalent compounds of antimony and arsenic lies in the observation that with antimony no immunity due to acclimatisation is acquired, either by the blood parasites or by the animal organism, whereas in the case of arsenic immunity towards increasing doses is a characteristic property. The toxicological properties of antimony are very similar to those of arsenic; as a rule, antimony compounds which are insoluble in water have little or no toxic properties. Ranken (Roy. Soc. Proc., 1913, B 86, 203) has studied the effect of intravenous injection of antimony on trypanosomes circulating in the blood. These are all killed within 20 minutes. At the same time a considerable percentage of the leucocytes is also destroyed, but a stimulus is set up which leads temporarily to an overproduction of leucocytes until equilibrium is again established. The therapeutic properties of corresponding derivatives of antimony and arsenic show no

parallelism either in character or degree. Many antimony compounds show a specific difference in their action on trypanosomes and spirochaetes, being decidedly more active towards the former. Such pronounced selective activity is not found among arsenic compounds. Observations made on arsenic compounds with regard to the influence of the constitution of the organic portion of the molecule on therapeutic or toxic properties are not valid for the corresponding antimony compounds. Arsacetin is very slightly active but the corresponding antimonoacetin (stibacetin) is strongly active; salvarsan is very strongly active but "antimony salvarsan" is quite inactive. These differences in the relation between constitution and activity of similar compounds may be due to the greater ease with which antimony is split off from its organic derivatives, so that the specific properties of the organic state of combination are more readily lost in the organism. For the same reason it is more difficult to suppress the poisonous properties of antimony by organic combination. The organic derivatives of bismuth are still less stable. On the other hand, the complex salts of metals of the arsenic group increase in stability with the atomic weight of the metal, and in this direction new valuable therapeutic agents may be looked for. Certain combinations of arsenic and antimony derivatives have shown useful results.—J. F. B.

PATENTS.

Acetic anhydride and polymerised or non-polymerised acetic aldehyde; Process for the production of —. Soc. Chim. des Usines du Rhône, Paris. Eng. Pat. 110,906, June 19, 1917. (Appl. No. 8810 of 1917.) Under Int. Conv., Oct. 30, 1916.

THE decomposition of ethylidene diacetate into acetaldehyde and acetic anhydride (see Eng. Pat. 23,190 of 1914; this J., 1915, 982) can be effected almost quantitatively, without formation of tar, by heating in a vacuum with the addition of an acid or acid salt as catalyst. The acetaldehyde which is produced distils in the form of paraldehyde. —D. F. T.

Pharmaceutical products [bromodiethylacetylurethanes of N-acetylated-p-aminophenols]; Manufacture of new —. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Leverkusen, Germany. Eng. Pat. 114,680, Apr. 23, 1917. (Appl. No. 5669 of 1917.)

p-ACETYLAMINOPHENOL, 153 parts, suspended in 1500 parts of acetone, is treated with 600 parts of bromodiethylacetylisocyanate until the mixture is dissolved. After standing several hours, the precipitate is filtered off, washed with ether, and recrystallised from alcohol. Alternatively, 213.5 parts of bromodiethylacetyl chloride is added slowly to a mixture of 194 parts of p-acetylaminophenolurethane and 121 parts of dimethylaniline, the mass being heated for a short time at $70^\circ C$. to complete the reaction; 500 parts of acetone is subsequently added and the product separated. The bromodiethylacetylurethane of

p-acetylaminophenol thus obtained melts at 141° C. Compounds of this group are useful in pharmacy as nervines and sedatives.—J. F. B.

Mercury compounds of the acridine series and process of making same. P. Hüsey and M. Hartmann. Assignors to Society of Chemical Industry in Basle, Switzerland. U.S. Pat. 1,259,517, Mar. 19, 1918. Date of appl., Nov. 28, 1917.

YELLOWISH-BROWN powders of value as therapeutic agents and antiseptics are prepared by the action of a soluble mercury salt on an acridine dyestuff alkylated at the characteristic nitrogen atom; these products give yellowish-green solutions in water, and solutions in alcohol, acetic acid, and acetone which at great dilution show yellowish-green fluorescence, and solutions with intense green fluorescence in sulphuric acid. The mercury compound obtained from 3,6-diamino-2,7-dimethyl-acridine, which has been previously heated with methyl chloride under pressure, is particularly specified.—D. F. T.

Glycols; Manufacture of.—*Manufacture of glycols and glycol derivatives.* P. McElroy, Washington, D.C. Assignor to Chemical Development Co. U.S. Pats. (A) 1,259,757 and (B) 1,259,758, Mar. 19, 1918. Dates of appl., Jan. 25, 1917, and Mar. 29, 1913.

(A) A MIXTURE of ethylene-, propylene-, and butylene-glycols is obtained by chlorinating oil-gas which has been heated to about 700° C. and hydrolysing the resulting mixture of dichlorides by heating under pressure with water and calcium carbonate. (B) A mixture of alkylene halides prepared from oil-gas is heated under pressure with an aqueous solution of a suitable salt of a weak acid, e.g., calcium acetate.—D. F. T.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

*Pigments; Covering power of—*with special reference to photographic prints. F. F. Renwick. Phot. J., 1918, 58, 140—153.

THE reflection density of a diffusing medium coated on a reflecting base is dependent on the reflecting power of the base, the surface reflection of the coating, and the optical properties of the diffusing particles suspended in the medium. Starting with the expressions deduced for the latter in a paper by himself and others on the

opacity of diffusing media (this J., 1918, 224 A), the author works out a mathematical expression for reflection density, D_r , in terms of ρ , the surface reflection, R_b , the reflecting power of the base, r_∞ , the maximum reflectance of the medium with increasing thickness, λ , a constant expressing the rate at which r_∞ is approached (this corresponds with the term "covering power"), and m , the quantity of the diffusing medium per unit area—thickness of coating or concentration of diffusing particles. Usually the reflecting power is determined in comparison with that of the base, or of the base plus medium without diffusing particles in the case of photographic prints, and the final expression for reflection density includes this comparison; it is of such a form that the curve connecting D_r and m for any value of R_b is part of the whole curve for the special case where $R_b=1$, the origin being moved by an amount representing the departure of the base from a pure white. When the factor r_∞ is very small, as in the case of photographic prints where the diffusing particles are very dark, a much simpler approximate expression is obtained and examples are given showing the close agreement between this approximation and actual observation; in this case m is taken as proportional to transmission density by diffused light with oil contact between the instrument opal and the density. The expression for reflection density previously suggested by Jones, Nutting, and Mees (this J., 1915, 250), which introduces only surface reflection, reflection of the base, and transmission density, is also discussed.—B. V. S.

*Photometer: A convenient accurate—*for the measurement of photographic densities. D. E. Benson, W. B. Ferguson, and F. F. Renwick. Phot. J., 1918, 58, 155—161.

THE photometer is an improved form of the Ferguson-Renwick photometer (Phot. J., 1911, 405, and 1914, 167), based on the law of inverse squares and using only one lamp for illuminating the density and for the variable comparison beam. An electric lamp with a small gridiron filament illuminates two pieces of opal set with their upper surfaces flush with the upper surface of a horizontal table. The front opal is directly over the lamp; the back opal is illuminated by means of a system of mirrors, two of which travel on a carriage sliding on horizontal bars, thus enabling adjustment of the effective distance between the lamp and the opal. The beams of light from the two opals are brought together in a horizontal tube by a mirror over the back opal and a Lummer-Brodhun cube over the front opal. A pointer on the mirror carriage passes along a scale logarithmically calibrated to give direct readings in densities. The length of the scale is about 22 inches and reads up to 1.8; by the use of a supplementary density in the comparison beam densities up to 2.8 may be measured, and it is suggested that the use of the much more powerful Pointolite lamp would enable the measurement of densities up to 4. The viewing tube is pivoted to swing out of the way, allowing the accurate placing of the negative on the table, which is large enough to permit the measurement of any part of a half-plate. The whole instrument may be tilted on an axis parallel to the slide bars to bring the viewing tube into convenient position. An auxiliary mirror attachment is provided in the table to give illumination of materials at an angle of 45° from above for the measurement of reflection densities.—B. V. S.

Photographic films of varying porosity ; Method of producing — J. H. Christensen, Søllerød, Denmark. U.S. Pat. 1,256,981, Feb. 19, 1918. Date of appl., Mar. 9, 1916.

SEE Fr. Pat. 481,149 of 1916 ; this J., 1917, 164.

XXII.—EXPLOSIVES ; MATCHES.

PATENT.

Nitro compounds and process of making same from tar-oils. J. R. Mardick, New York. U.S. Pat. 1,258,587, Mar. 5, 1918. Date of appl., Jan. 17, 1917.

IMPURE coal tar, water-gas tar, or producer-gas tar distillate containing compounds removable by crystallisation and repeated washing with 2½ to 5% of sulphuric acid or 5% solution of soda-ash, is subjected to the action of a strong mineral nitrating acid between 10° and 60° C., the strength being gradually increased by the addition of strong acid. The polynitro compound is partially soluble in water, benzene, and toluene ; it is of brownish colour, non-crystallisable, and semi-fluid below 60° C., above which it is fluid. It is partly soluble in nitroglycerin at 45° C., and completely miscible with it at ordinary temperatures.—L. A. C.

XXIII.—ANALYSIS.

Potash ; Determination of — B. Blount. Analyst. 1918, 43, 117—120.

To determine potash in siliceous rocks, clays, etc., from 0.5 to 2 grms. of the very finely ground sample is digested for some hours with 10 c.c., or more, of hydrofluoric acid and 2 c.c. of sulphuric acid, the mixture is then evaporated, heated until most of the sulphuric acid has been expelled, the residue of sulphates digested with hydrochloric acid and water, and the mixture filtered. The insoluble portion is again treated with hydrofluoric acid, etc. The filtrate is treated with bromine and ammonia to precipitate iron, aluminium, and manganese, and, after filtration, the calcium is precipitated as oxalate. The filtrate from the calcium oxalate is evaporated to a small bulk, nitric acid is then added and the mixture evaporated until sulphuric acid fumes appear. After cooling, the residue is dissolved in a few c.c. of dilute hydrochloric acid, a slight excess of barium hydroxide solution is added, the barium sulphate is separated by filtration, and the excess of barium salts in the filtrate removed by treatment with ammonium carbonate. The solution is then evaporated with hydrochloric acid, the residue heated to expel ammonium salts, treated with a few drops of ammonium carbonate solution, filtered, again evaporated, ignited gently, and weighed. The potassium in the mixed alkali chlorides thus obtained is determined by precipitation with platinum chloride or by means of the perchlorate method.—W. P. S.

Copper, zinc, cadmium, nickel, and cobalt ; Determination of — [as carbonates]. A. Carnot. Ann. Chim. Analyt., 1918, 23, 69—75.

WHEN copper, zinc, cadmium, nickel, and cobalt are precipitated as carbonates by means of sodium carbonate, the precipitation is incomplete and the precipitate always retains a quantity of alkali carbonate. If, however, a solution containing a salt of these metals is treated, in the cold, with a slight excess of sodium carbonate, and ammonia or ammonium carbonate then added in quantity just sufficient to dissolve the precipitate and the

mixture boiled, the metal is precipitated completely as carbonate or oxide. The boiling should be prolonged for at least 5 mins. and the volume of the solution should be about 200 c.c. for 0.5 gm. of metal. In the case of copper, nickel, and cobalt, ammonia or ammonium carbonate may be used ; for zinc, ammonium carbonate gives a precipitate of better physical character than does ammonia, whilst a mixture of ammonia and ammonium carbonate must be used for cadmium.—W. P. S.

Bromine ions ; Detection and determination of — by means of fuchsin-sulphuric acid reagent. G. Denigès and L. Chelle. Ann. Chim. Analyt., 1918, 23, 81—83.

A METHOD described previously (this J., 1913, 141) is modified as follows in order to prevent the interference of nitrites should these be present. Five c.c. of the bromide solution (containing not more than 1 gm. of bromine per litre) is mixed with 4 drops of hydrochloric acid, 4 drops of 10% potassium chromate solution, and 1 c.c. of sulphuric acid, and the mixture is immediately cooled to 15° C. ; after 5 mins., 1 c.c. of the fuchsin reagent and 1 c.c. of chloroform are added, the mixture is shaken, and then allowed to separate. The intensity of the red coloration exhibited by the chloroform layer is proportional to the quantity of bromine present. The presence of 1 gm. of sodium nitrite in a solution containing 1 mgrm. of bromine does not prevent the detection of the latter. (See also J. Chem. Soc., June, 1918.)

—W. P. S.

Iodine in inorganic and organic compounds ; New general method for determining — N. Tarugi. Gazz. Chim. Ital., 1918, 48, I., 1—16.

THE iodine and chlorine in solutions of iodine trichloride such as are used for the sterilisation of water may be estimated by means of the reaction : $6\text{FeSO}_4 + 3\text{H}_2\text{SO}_4 + 2\text{ICl}_3 = 3\text{Fe}_2(\text{SO}_4)_3 + 2\text{I} + 6\text{HCl}$. The ferrous sulphate solution employed is prepared by dissolving about 14 grms. of the pure, crystallised salt in 100 c.c. of water and adding to the filtered liquid 100 c.c. of 2N-sulphuric acid ; the titre of this solution is determined exactly by titration with standard permanganate solution. The procedure is as follows : A definite volume of the iodine trichloride solution and exactly 25 c.c. of the ferrous sulphate solution are shaken vigorously in a separating funnel, left for 1½ hours, and then repeatedly extracted with chloroform until the latter is no longer coloured. The chloroform solutions are washed with a little water, which is afterwards extracted with fresh quantities of chloroform as long as the latter becomes coloured. The total chloroform, which contains in solution the whole of the iodine, is mixed with an equal volume of water and titrated with N/10-sodium thiosulphate solution. The aqueous solution which was extracted with chloroform and which consists of the acid ferrous sulphate, is filtered and an aliquot part of it titrated with N/10-permanganate solution, the result being calculated for the total volume including the volume of the iodine trichloride solution used : 1 c.c. of N/10-permanganate corresponds with 0.00355 gm. Cl. The total active halogens in the iodine trichloride solution may be estimated by direct titration of the solution with N/10-thiosulphate solution. Tables are given showing the relative proportions of iodine monochloride and trichloride corresponding with different values of the ratio, iodine : chlorine, and the concentrations of iodine trichloride by weight and by volume for solutions of specific gravities between 1.010 and 1.365.

This method may be applied to the estimation of iodine in both inorganic and organic compounds.

With an inorganic compound, this is dissolved or suspended in water, the vessel containing the liquid being surrounded with ice, and chlorine passed through until it becomes straw yellow and excess of chlorine is evident in the vessel. The tube through which the chlorine is passed is washed into the liquid, the latter being made up to a definite volume and an aliquot part treated with the standard ferrous sulphate solution, extracted with chloroform, and so on. When the iodine compound to be tested contains oxygen, it is mixed with an equal weight of sodium bisulphite before being treated with chlorine.

A few organic compounds containing iodine give up the latter as trichloride when suspended in water and treated with chlorine, but in most cases it is necessary to heat the compound with sulphuric acid while the chlorine is passed. Use may be made of a tubulated retort, the end of the tube being turned downwards and joined to a glass tube dipping into about 10 c.c. of water in a beaker kept cool by ice. The substance is introduced into the retort together with 5–10 c.c. of concentrated sulphuric acid, and chlorine is passed in, the liquid being gradually heated to boiling meanwhile. The iodine trichloride solution thus obtained is then treated as described above. All the organic compounds examined yield their iodine as trichloride under this treatment.—T. H. P.

Nitrogen; Kjeldahl's method for the determination of —. E. Salm and S. Prager. Chem.-Zeit., 1918, 42, 104–105.

WHEN a nitrogenous substance has been decomposed by digestion with sulphuric acid and mercury, or with sulphuric acid containing phosphoric anhydride and mercury, the subsequent distillation of the ammonia must be made with the addition of zinc dust if potassium sulphide is not used together with the requisite quantity of sodium hydroxide. If, however, potassium sulphide is used, zinc turnings or shavings may be employed in place of zinc dust. In the absence of zinc, or if this is replaced by aluminium, the results obtained are too low.—W. P. S.

Foam inhibitor in the Van Slyke amino-nitrogen method. H. H. Mitchell and H. C. Eckstein. J. Biol. Chem., 1918, 33, 373–375.

DIPHENYL ether is recommended as an excellent substitute for isocaprolic alcohol for the prevention of foaming during the evolution of nitrogen in the Van Slyke method (this J., 1911, 771, 1135) of determining amino-nitrogen in animal and plant extracts.—H. W. B.

Malic and tartaric acids; Optical method for the determination of — in the same solution. J. J. Willaman. J. Amer. Chem. Soc., 1918, 40, 693–701.

THE method depends on the facts that uranyl acetate enhances the rotation of *l*-malic and *d*-tartaric acids (see this J., 1911, 1177, 1407), whilst ammonium heptamolybdate reverses the sign of rotation of malic acid, giving strongly dextro-rotatory solutions with each acid. It is designed for solutions containing from 0.1–0.6 or 0.8 grm. of each acid, the necessary volume of liquid, e.g., apple juice, being ascertained by titration. The acids are precipitated as their barium salts and liberated again, and then aliquot parts are mixed with the two activating agents and examined in the polarimeter. The two readings are referred to a chart which is prepared by plotting the rotations of different mixtures activated by uranyl acetate against those of the same mixtures plus ammonium heptamolybdate. The curves cross, and the point of intersection in a given case corresponds with the weight of malic

acid along one axis and the tartaric acid along the other. (See further, J. Chem. Soc., June, 1918.)—J. C. W.

Metals; Apparatus for testing the hardness of —. Reid Bros. (Engineers), Ltd., London, and G. Brown, South Norwood, Surrey. Eng. Pat. 114,593, May 22, 1917. (Appl. No. 17,231 of 1917.)

THE specimen to be tested is placed on an anvil,

and an indenting member with a hardened point slides in a vertical guide and rests freely on the specimen. Means are provided for dropping a ball or other known weight from a predetermined height on to the indenting member. The amount of indentation is measured by means of the deflection of a beam of light by the angular movements of a small mirror, which is mounted on a flat spring so arranged that it is deflected by a collar on the indenting member to an amount depending on the depth of penetration of the specimen. This indentation is compared with that produced in a standard specimen.—W. F. F.

Melting-points; Method and apparatus for determining—L. W. Chubb, Edgewood Park, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,259,363, Mar. 12, 1918. Date of appl., May 6, 1915.

THE sample to be tested is supported on a member of refractory conducting material which is heated by the passage of an alternating current, and which forms with another connected member a thermoelectric couple. The terminals of the supporting member are connected by a non-inductive resistance, and a direct current measuring instrument has its terminals connected to the second member of the thermoelectric couple, and to the neutral point of the resistance respectively.—W. F. F.

Flue-gases; Apparatus for determining the quantity of carbon dioxide in—Z. Olsson, Assignor to A. Rust-Oppenheim, New York. U.S. Pat. 1,260,020, Mar. 19, 1918. Date of appl., Mar. 29, 1917.

THE gas is passed through a closed receptacle containing a buoyant expansible body adopted to rise and fall with changes in the density of the gas. The movements of the body are indicated by connecting it to a pointer moving over a graduated scale.—W. F. F.

Patent List

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Aubert. Furnaces. 7473. May 3. (Fr., Mar. 10, 1917.)

Beeby. Apparatus for filtering and straining liquids. 7583. May 6.

Cooper and Griffiths. Apparatus for evolving gases from liquids. 7515. May 4.

Cunningham. Separation of liquid mixtures. 7530. May 4.

Fox. Dehydrating and desiccating apparatus. 7382. May 2.

Harvey, and Harvey Gas Furnace Co. Regenerative or recuperative furnace installations. 7529. May 4.

Hodson. Kiln for incinerating earthy matters. 7623. May 7.

Linden. 7464. See XIX.

Linden. 7430. See XII.

Mann. Drying, concentrating, or evaporating liquids or semi-liquids. 7518. May 4.

Petrie. Machines for drying granular or fibrous materials. 7612. May 7.

Reynard. Effecting rapid crystallisation of substances in solution. 7959. May 11.

Rudge, and United Alkali Co. Apparatus for subjecting matter to the action of gases or vapours, for making bleaching-powder, etc. 7875. May 10.

Wilson. Automatic stills. 7541. May 6.

COMPLETE SPECIFICATIONS ACCEPTED.

43 (1917). Marks (Isko, Inc.). Refrigerating apparatus. (115,051.) May 8.

884 (1917). Aylsworth and others. See XX.

5829 (1917). Testrup, and Techno-Chemical Laboratories, Ltd. Conducting high-temperature reactions. (115,087.) May 8.

7867 (1917). Enock & Co., and Enock. Jacketed vats for heating and cooling liquids. (115,126.) May 8.

7940 (1917). Roy, and Morson and Son. Means for purifying and absorbing gaseous products of chemical reactions. (115,311.) May 15.

9015 (1917). Jeffcock and Yardley. Separating water and other matter from compressed air and other gases. (115,325.) May 15.

11,539 (1917). Bloxam (Zellstoffabrik Waldhof). Disposal of waste gases from chemical operations. (115,350.) May 15.

16,135 (1917). Schlatter and Frorath. Drying-installations. (115,193.) May 8.

18,516 (1917). Marks (Isko, Inc.). Refrigerating apparatus. (115,208.) May 8.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Arkell. Artificial fuels, and processes for manufacturing same. 7803. May 9.

Ballingall and others. 7557. See VII.

Boissier. Solid fuel. 7862. May 10. (Fr., May 10, 1917.)

Corthésy. Distillation of liquid hydrocarbons. 7315. May 1.

Corthésy. Generation of gas from coal dust, etc. 7710. May 8.

Glover, West, and Wild. Retorts for continuous carbonisation of coal, etc. 7586. May 6.

Harger. 7772. See VII.

Lamberty. Manufacture of briquettes. 7528. May 4.

Leadbeater. Means for drying and carbonising peat, etc. 7415. May 3.

Maseyk. Automatic coal-gas producer. 7765. May 9.

Parker. Generation, from incandescent carbonaceous material, of fuel gas for internal-combustion engines. 7435. May 3.

Soddy. Stripping illuminants from and purifying coal gas by means of charcoal. 7698. May 8.

Stevenson. Fuel. 7263. May 1.

Stobart. Washers for coal, etc. 7246. Apr. 30.

Thuman. Apparatus for feeding fuel, etc., to gas-producers. 7532. May 4.

COMPLETE SPECIFICATIONS ACCEPTED.

11,575 (1916). Riedel. Operation of gas generators. (101,220.) May 8.

16,469 (1917). Soc. Franco-Belge de Fours à Coke. Horizontal coking ovens. (113,779.) May 8.

5095 (1918). Gaunt and others. See X.

III.—TAR AND TAR PRODUCTS.

COMPLETE SPECIFICATIONS ACCEPTED.

5567 (1917). Thuman (Evans). Manufacture of toluol. (115,066.) May 8.

6035 (1917). Inray (Soc. Chem. Industry in Basle). Manufacture of β aminoanthraquinone, (115,259.) May 15.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

Clark (Chem. Fabr. Worms). Colours soluble in oils and fats, and process of preparing same. 7719. May 8.

Dydynski. Manufacture of sulphur colour for printing textile fabrics, etc. 7475. May 3.

Imray (Soc. Chem. Industry in Basle). Manufacture of mordant-dyeing azo dyestuffs and metal compounds thereof, and their application in dyeing. 7816. May 9.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Brégeat. Recovery of acetate of cellulose from industrial waste material. 7809. May 9. (Fr., Dec. 1, 1917.)

Carper and Tulloch. Extraction of fats, etc., from wool. 7255. Apr. 30.

Dreyfus. Manufacture of compositions or articles having a basis of cellulose acetate. 7192 and 7193. Apr. 29.

Groves and Ward. 7177. See XIII.

Harvey. 7740. See XIII.

Johnston and Sutherland. Degumming or cleansing stalk fibres. 7486. May 4.

Moore. Production and treatment of fibrous materials. 7312. May 1.

Robbins. 7907. See XIII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Barnes, and Spence & Sons. Mordanting vegetable fibres. 7829. May 10.

Dydynski. 7475. See IV.

Dydynski. Dyeing with direct (substantive) cotton colours. 7656. May 7.

Imray (Soc. Chem. Ind. in Basle). 7816. See IV.

Robertson. Printing woven fabrics. 7547 and 7826. May 6 and 10.

COMPLETE SPECIFICATIONS ACCEPTED.

5785 and 9702 (1917). Farrar and Whitehead. Dyeing machines, washing-off machines, etc. (115,082.) May 8.

6339 (1917). Albrecht. Production of printed cloths. (115,106.) May 8.

6414 (1917). Calico Printers' Assoc., and Fourneaux. Production of black on vegetable fibres. (115,278.) May 15.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Ballingall, and R. and J. Dempster. Heat-controlling means for hydrogen-gas plants. 7557. May 6.

Becket. Manufacture of calcium carbide. 7239 and 7240. Apr. 30.

Blumenberg. Treatment of borax ores. 7848. May 10.

Dutt and Dutt. Manufacture of aluminium chloride, aluminium-sodium chloride, and carbonates of soda and potash. 7841. May 10.

Gros et Bouchardy. Manufacture of nitric anhydride. 7392. May 2. (Switzerland, May 16, 1917.)

Gros et Bouchardy. Manufacture of nitric acid. 7393 and 7394. May 2. (Switzerland, June 2 and 16, 1917.)

Harger. Manufacture of hydrogen. 7772. May 9.

Heberlein and Mond. Production of preparations containing colloidal copper compound. 7576. May 6.

Hirst. Recovery of rare earths. 7216. Apr. 30.

Hulin. Preparation of anhydrous metallic chlorides. 7661. May 7.

Jones and Parsons. Process of oxidising ammonia, and catalytic bodies. 7221. Apr. 30.

Mackintosh. Extraction of radioactive substances from silicious and aluminous materials. 7819. May 9.

Rideal and Taylor. Manufacture of hydrogen. 7232. Apr. 30.

Rudge, and United Alkali Co. 7875. See I.

COMPLETE SPECIFICATIONS ACCEPTED.

6317 (1917). Westling and Andersen. Separation of molybdenum compounds. (115,274.) May 15.

8126 (1917). Richards. See VIII.

10,286 (1917). Grossmann. Method of obtaining nitre-cake in a disintegrated or ground form. (115,340.) May 15.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Marlow. Ovens or kilns for making tiles, pottery, etc. 7487. May 4.

Parsons. Glass furnaces. 7638. May 7.

Steele. Sifting apparatus for potters' slip, glaze, etc. 7488. May 4.

COMPLETE SPECIFICATIONS ACCEPTED.

1339 (1917). Chambers. Manufacture of glass. (103,672.) May 15.

8126 (1917). Richards. Furnaces or kilns for calcining limestone, fireclay, or other refractory materials. (115,316.) May 15.

8536 (1917). Soc. Nouv. des Etabl. E. Muller. Baking graphite crucibles, bricks, and other refractory objects having graphite for a base. (109,247.) May 15.

IX.—BUILDING MATERIALS.

APPLICATION.

Hadfield and Hadfield. Manufacture of concrete. 7919. May 11.

COMPLETE SPECIFICATIONS ACCEPTED.

6121 (1917). Middlesboro' Slag Co., and Major. Manufacture of slag bricks. (115,100.) May 8.

11,419 (1917). Ito. Heat-insulating compounds. (115,163.) May 8.

14,247 (1917). Abraham. Roofing materials. (113,778.) May 8.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Aitken. Crucible furnaces for melting metals. 7474. May 3.

Ashcroft. Manufacture of magnesium by electrolysis. 7245. Apr. 30.

Ashcroft. Manufacture of magnesium or its alloys by electrolysis. 7705. May 8.

Ashcroft. Treatment of complex or refractory sulphide ores or products. 7706. May 8.

Bowes. Aluminium soldering process. 7289. May 1.

Burnett and Jones. Case-hardening materials. 7556. May 6.

Burr. Admixture of metals or substances for alloying. 7311. May 1.

Clevenger. Electrolytic production of zinc. 7665 and 7667. May 7. (U.S., May 7, 1917.)

Crocker and Crocker. Manufacture of zinc. 7505. May 4.

Edser, Tucker, and Minerals Separation, Ltd. Concentration of ores. 7742. May 8.

Elmore. Extraction of lead and zinc from their ores. 7732. May 8.

Gröndal. Mechanical roasting-furnace. 7650. May 7. (Sweden, Mar. 24, 1917.)

Mayrow. Apparatus for chemical and electro cleaning and depositing metals. 7188. Apr. 29.

Mordey. Heat-treatment of iron and steel and their alloys. 7752. May 8.

Stabilimenti Biak. Process for melting metals. 7648. May 7. (Ital., May 7, 1917.)

Wright and Eagle Range, Ltd., and Yates. Tilting crucible furnaces. 7457. May 3.

COMPLETE SPECIFICATIONS ACCEPTED.

16,310 (1916). Reichenstein. Protecting iron surfaces from chemical action. (103,814.) May 15.
1674 (1917). Faulkner. Electric furnaces for melting or refining non-ferrous alloys. (115,248.) May 15.

5835 (1917). Ross and Crump. Extraction of copper or other metals from ores, etc. (115,088.) May 8.

6240 (1917). Temple. Composition for use in welding steel or wrought iron. (115,102.) May 8.

8653 (1917). Rollason. Combined tilting and reverberatory open-hearth melting-furnace and converter. (115,323.) May 15.

10,385 (1917). New Delaville Spefter Co., and Shortman. Extraction of zinc. (115,409.) May 15.

16,129 (1917). Stabilimenti Biak. Metal alloys. (111,288.) May 15.

17,325 (1917). Kimbell. Separation or concentration of ores. (115,199.) May 8.

5095 (1918). Gaunt, Brookfield, and Tylor and Sons. Means for preheating the charge in crucible and like furnaces. (115,222.) May 8.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Armelin. Dry batteries. 7727. May 8.

Ashcroft. 7245 and 7705. *See* X.

Bowen and Marino. Secondary batteries. 7175. Apr. 29.

Campbell and Gow. Control of power absorbed in electric furnaces. 7957. May 11.

Clevenger. 7665 and 7667. *See* X.

Hawkins. Accumulator cell. 7387. May 2. (U.S., May 2, 1917.)

Mayrow. 7188. *See* X.

COMPLETE SPECIFICATIONS ACCEPTED.

18,338 (1916). Ajax Metal Co. Induction furnaces. (103,645.) May 15.

1588 (1917). British Electric Transformer Co., and Berry. Electric furnaces and transformers for use therewith. (115,247.) May 15.

1674 (1917). Faulkner. *See* X.

15,815 (1917). Dean, and Chloride Electrical Storage Co. Electric accumulators. (115,374.) May 15.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Carper and Tulloch. 7255. *See* V.

Linden. Separating, recovering, and washing oil, grease, fat, etc., from water, etc., or separating two liquids of different densities. 7430. May 3.

Janaka. Manufacture of soap containing sulphur. 7249. Apr. 30. (Japan, Aug. 1, 1917.)

COMPLETE SPECIFICATION ACCEPTED.

6761 (1917). Huntington and Barnes. Soap. (115,110.) May 8.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Clark (Chem. Fabr. Worms). 7719. *See* IV.

Groves and Ward. Dopes or varnishes for aeroplanes. 7177. Apr. 29.

Harvey. Dopes for fabrics. 7740. May 8.

Robbins. Preparation of dope for treating fabrics for aircraft. 7907. May 10.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Clark (Chem. Fabr. Worms). Tanning animal hides. 7720. May 8.

Haack and Testas. Tanning fishing-nets. 7526. May 4.

Kay and Platt. Automatic tanning plant. 7694. May 8.

Weiss. Manufacture of horny masses from casein, etc. 7479. May 3. (Germany, Apr. 28, 1917.)

XVI.—SOILS; FERTILISERS.

APPLICATIONS.

Brown. Grub-resisting fertilising material. 7684. May 8.

Furse. Manufacture of manure from refuse. 7843. May 10.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATION.

Lang. Manufacture of syrup from beetroot. 7762. May 9.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Adams. Vegetable meal and/or flour. 7551. May 6.

Johnston and Kearney. Preservation of food-stuffs. 7784. May 9.

Linden. 7430. *See* XII.

Linden. Means for drying sludge, etc. 7464. May 3.

COMPLETE SPECIFICATIONS ACCEPTED.

6086 (1917). Bendixen. Method of making soluble the nucleo-albumins in preserved eggs. (115,261.) May 15.

17,607 (1917). Reisert Ges. Process of softening water. (112,127.) May 8.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Newton (Bayer and Co.). Manufacture of a pharmaceutical product. 7867. May 10.

Newton (Bayer and Co.). Manufacture of dialkylbromoacetylurea. 7868. May 10.

COMPLETE SPECIFICATIONS ACCEPTED.

884 (1917). Aylsworth, and Savings Investment and Trust Co. Apparatus for performing organic chemical reactions. (103,665.) May 8.

5755 (1917). Callimachi. Manufacture of salicylic acid. (115,080.) May 8.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATION.

Keerotype, Ltd., and Middleton. Photographic printing-paper and transfer processes. 7641. May 1.

XXIII.—ANALYSIS.

APPLICATION.

Richardson. Means for testing hardness of materials. 7825. May 10.

COMPLETE SPECIFICATIONS ACCEPTED.

12,102 (1917). Guillemin, and Comp. des Forges d'Audincourt et Dépendances. Calorimetric meters. (115,354.) May 15.

14,096 (1917). Siemens und Halske A.-G. Photometry and apparatus therefor. (112,614.) May 8.

I.—GENERAL ; PLANT ; MACHINERY.

Gas reactions; Method of obtaining general velocity curves for complete homogeneous — at constant pressure. G. W. Todd. *Phil. Mag.*, 1918, **35**, 435—444.

REACTION velocity curves for bimolecular and termolecular reactions at constant pressure have been plotted, and their application to technical gas reactions is referred to. The graphs have reference to termolecular reactions of the type $2A + B$ with either A or B in excess, and afford directly the percentage of the original substances which has undergone transformation after different time intervals. The technically important cases, in which the reaction products occupy two-thirds and one-third respectively of the volume of the reacting substances, are both dealt with in the paper. (See also *J. Chem. Soc.*, 1918, ii., 190.)—H. M. D.

PATENTS.

Condensers or coolers for gases or liquids. E. C. Stables, and J. and E. Hall, Ltd., Darford, Kent. Eng. Pat. 114,651, Apr. 5, 1917. (Appl. No. 4893 of 1917.)

A SHALLOW casing is provided with two partitions arranged in spiral form or of any modified shape, and coiled in opposite directions so as to form a tortuous passage leading from the circumference to the centre and back to the circumference in the opposite direction. The cooling medium is passed through the passage. A number of tubes for the fluid to be cooled are arranged in the passage and are connected in parallel at each end to a single inlet or outlet box inside the casing, from which an inlet or outlet pipe passes through the casing. The cooling fluid may pass through the passage in the same or in the opposite direction to that of the fluid to be cooled. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pat. 936 of 1874.)—W. F. F.

Condensers for acids. W. Hayhurst, Accrington. Eng. Pat. 114,706, May 30, 1917. (Appl. No. 7737 of 1917.)

A CONDENSER for acids, such as nitric and hydrochloric acids, comprises a vessel of prismatic form having a cross-section of triangular or other form with large cooling surface area. In one form the cross-section may be of inverted T-shape. A series of such vessels is arranged in a sloping tank, the vessels being connected at the bottom.—W. F. F.

Drying medium; Method of and apparatus for producing a —. L. C. Sadezky, London. Eng. Pat. 114,810, Feb. 19, 1918. (Appl. No. 2888 of 1918.)

A DRYING medium suitable for drying clothing, textile fabrics, powder, liquids, or semi-liquids such as milk, eggs, and the like, is produced by separating the moisture from air by cooling with liquid

ice is deposited, and thence to the conduit, E, liquid air being sprayed in at F. The mixture passes into a second depositing chamber, G, and the dry air then passes through a conduit, H, provided with steam heating pipes, J. The dry hot air is withdrawn for use by a fan, K.—W. F. F.

Dehydrating-machine for desiccating liquids. T. J. Coster and D. G. Putnam, Chicago, Ill. U.S. Pat. 1,258,988, Mar. 12, 1918. Date of appl., Feb. 2, 1917.

A STATIONARY cylindrical casing having means to supply heated gas to its interior is mounted on a rotary shaft. A drum within the casing is secured at one end to the shaft and at the other end is provided with an annular ring which is journaled on a stationary disc. A feed pipe passes through the disc and supplies the fluid to be dried to the interior surface of the drum. The dried material is removed from the drum by means of a scraper carried by the disc, and a conveyor carries it out of the machine.—J. H. P.

Drying machine. F. G. Sargent, Westford, Assignor to C. G. Sargent's Sons Corporation, Graniteville, Mass. U.S. Pat. 1,259,675, Mar. 19, 1918. Date of appl., July 11, 1917.

THE machine consists of a casing, inside which is a movable screen to support the material to be dried. Heated air is conducted to the space above the screen and passes through the screen to a number of passages, through which part of the air is returned to the heating chamber and used again, whilst the remainder passes to the exhaust.

—J. H. P.

Heat interchanging apparatus; Tubular —. E. L. Pease, Hurworth Moor, A. Bell, and The British Still Tube Co., Ltd., Darlington. Eng. Pat. 114,863, Mar. 6, 1917. (Appl. No. 3327 of 1917.)

IN an apparatus for heating air by means of steam, a number of heating units are arranged in two tiers. Each unit consists of a pair of vertical rectangular headers connected by horizontal tubes provided with vertical metal radiating ribs, e.g., by expanding the tubes. Openings are provided in the headers for the insertion of an expanding tool and for cleaning purposes. The headers of several units are adapted to fit together so as to form the side walls of the conduit through which air to be heated is passed by pressure or suction. The front headers are divided horizontally into two compartments so that the steam passes through the upper pipes and returns through the lower pipes, and the units are connected to a common steam supply pipe above the apparatus and to a common return pipe for condensed water below the apparatus, valves being provided so that any or all of the units may be put into action. The upper and lower compartments of the upper tier of front headers are connected by intermediate pipes to the upper and lower compartments of that front header of the lower tier which is below the adjacent upper unit, so that all the connecting pipes are inclined. The first unit in the lower tier and the last unit in the upper tier have a direct valved connection with the steam supply pipe, and the last unit in the upper tier has a direct valved connection with the return pipe for condensed water.—W. F. F.

Evaporators, steam generators, steam separators, or the like apparatus; Anti-priming devices or baffle plates for —. H. Fay, Liverpool. Eng. Pat. 114,888, Apr. 18, 1917. (Appl. No. 5432 of 1917.)

AN anti-priming device for evaporators comprises two horizontal sets of annular or spiral baffles which intermesh with one another and divide the evaporator horizontally into two parts. The baffles are each carried by a horizontal plate, the upper set

air. A fan, B, forces air into a conduit, A, and liquid air is sprayed in at the contracted passage, C. The mixture passes into the chamber, D, where

being suspended from a rod which screws through the top of the casing so that the extent of intermeshing of the baffles may be regulated. An indicating pointer may be attached to the screwed rod so as to indicate the position of the baffles on a scale. The steam passes upwards through a central opening in the lower plate and then radially outwards in a zigzag path over the baffles, while the separated water escapes through perforations in the lower plate into a conduit from which it flows back into the water space of the evaporator. The edges of the baffles may be beaded, flanged, or curved inwards against the direction of steam flow.—W. F. F.

Separating liquids of different specific gravity, insoluble or difficultly soluble in each other, such for instance as an emulsion or mixture of grease and water. J. Carroll, Wigan. Eng. Pat. 114,921. May 15, 1917. (Appl. No. 6913 of 1917.)

THE warm or hot emulsion of grease and water is placed in a chamber provided with an internal contracted neck at the top, the space surrounding the neck being filled with cold water. A short tube fits into the neck and the grease solidifies in the tube, which may then be withdrawn and the grease removed by pulling a scraping disc through the tube. In a modification, the vessel into which the emulsion is passed at the bottom, may be provided with a horizontal partition, having openings over which inverted funnels are placed to collect the solidified grease. The top of each funnel is flared outwards, and all may be united by shallow channels. One may be provided with a lip for the overflow of water. The apparatus is specially applicable for recovering fats from water used for washing sheep. Soluble fats are previously rendered insoluble by the addition of sulphuric acid.—W. F. F.

Liquids and gases, vapours, fumes, and the like; Apparatus for bringing — into intimate contact. W. B. Davidson, and W. C. Holmes and Co., Ltd., Huddersfield. Eng. Pat. 115,006, Jan. 18, 1918. (Appl. No. 1025 of 1918.)

IN an apparatus of the type described in Eng. Pat. 9302 of 1914 (this J., 1914, 1682), a number of shallow trays, *e*, with upturned edges, *d*, *e*, are superposed in a casing, *a*, and liquid overflows from one to the other by pipes, *f*, which dip into

the spraying vessels, *k*. These vessels are mounted on a rotating shaft, *b*, and carry short radial projecting pipes, *l*, to which spraying vanes, *m*, having scoop portions, *m'*, are secured. The upper portions of the vanes are serrated and an additional scoop, *p*, may be provided. The gas to be treated passes upwards through the apparatus as shown by the arrows, and its contact with the spray is facilitated by the inclined deflecting plate, *h*. Rotation of the liquid is prevented by radial plates, *q*, and additional radial ribs may be provided to act

as gas scrubbers. In a modification, the arms carrying the sprayers are formed as tangential tapering extensions from the vessels, *k*, so that the liquid is directed towards the vanes. In another modification a horizontal annular plate may extend inwards from the plate, *h*, and may be provided with radial slots to distribute the gas.

—W. F. F.

Refrigerating apparatus. M. F. Ewen and A. L. S. McCurdy, Chicago, Ill., Assignors to Larsen Ice Machine Co. (Inc.), Wilmington, Del. U.S. Pat. 1,259,006, Mar. 12, 1918. Date of appl., Nov. 4, 1915.

BETWEEN the absorber and the still and connected with them by valved pipes is a measuring device, and the valves are operated alternately, so that at definite intervals predetermined amounts of saturated absorbent are transferred from the absorber to the still by gravity. Between the expansion chamber and a combined condenser and liquid receiver is a positively operated valve which is actuated in fixed time relation with the valves controlling the inlet and outlet of the measuring device.

—J. H. P.

Dust filter and the like. G. H. Fraser, Brooklyn, N.Y. U.S. Pat. 1,259,008, Mar. 12, 1918. Date of appl., Apr. 20, 1915.

A NUMBER of chambers connected with a common exhaust and a common inlet main, are each provided with a filter chamber through which the dust-laden gas is caused to flow. Any one of the chambers may be cut out of the circuit by means of valves, and other valves are provided by means of which a reverse flow may be induced through the chamber to clean the filter.—J. H. P.

Filter. C. W. Merrill, Berkeley, Cal. U.S. Pat. 1,259,032, Mar. 12, 1918. Date of appl., Dec. 8, 1915.

A NUMBER of flat circular filter elements are arranged parallel to one another and the liquid is directed against their surfaces by perforated radial pipes mounted on a central rotating supply conduit passing concentrically through all the filter elements. Each filter element is provided with an aperture extending from the centre to the side wall, and the solid material is removed mechanically through the aperture.—W. F. F.

Filter; Rotary suction —. O. J. Salisbury, Salt Lake City, Utah. U.S. Pat. 1,259,139, Mar. 12, 1918. Date of appl., May 24, 1917.

THE filter is formed of a series of similar units arranged side by side in spaced relation, each comprising a solution tank and a filter agent mounted to revolve therein. The filter agents are mounted on a longitudinal, hollow shaft above the tanks.

—J. H. P.

Classifier. A. L. Blomfield, Denver, Colo., Assignor to The Dorr Co. U.S. Pat. 1,260,135, Mar. 19, 1918. Date of appl., Apr. 21, 1916.

A HOLLOW container has an overflow for liquid and suspended matter and a flat bottom surface provided with an outlet for material which settles. Sweeps move the latter across the bottom towards the outlet, and a current of liquid introduced at the bottom lifts the finer solids to the overflow. The material is fed into the container below the level of the overflow.—J. H. P.

Pulveriser. J. C. Clark, Atlanta, Ga. U.S. Pat. 1,260,330, Mar. 26, 1918. Date of appl., Jan. 13, 1916.

A STATIONARY casing, 10, is provided with a discharge opening at the bottom, and an opening in one side in which a dish-shaped plate, 19, fits. This plate is carried by the cup-shaped member, 15, 16,

which is mounted on the horizontal shaft, 13, and provided with perforations in its base through which material is guided by the plate, 19. A sleeve, 22, is mounted to rotate on the shaft, 13, and carries a spider provided with peripheral pockets,

27, carrying grinding rolls which bear against the ring portion, 16, of the cup-shaped member. The shaft and sleeve carry pulleys and are independently rotated.—W. F. F.

Cooling towers of reinforced concrete; Construction of —. F. K. T. van Iterson, Heerlen, and G. Kuypers, Rotterdam, Netherlands. Eng. Pat. 108,863, Aug. 8, 1917. (Appl. No. 11,459 of 1917.) Under Int. Conv., Aug. 16, 1916.

Pulverising apparatus. R. A. Lachmann, Chicago, A. W. Raymond, Evanston, and W. B. Sensenau, Assignors to Raymond Bros. Impact Pulverizer Co., Chicago, Ill. U.S. Pats. 1,260,406 and 1,206,407, Mar. 26, 1918. Dates of appl., Oct. 23, 1915, and Mar. 31, 1917.

Separating particles from a fluid by combined centrifugal and filtering action; Method and means for —. K. and A. Ward, Stockholm. U.S. Pat. 1,262,146, Apr. 9, 1918. Date of appl., May 22, 1914. Renewed Oct. 23, 1917.

See Fr. Pat. 472,701 of 1914; this J., 1915, 479.

Annealing furnace. U.S. Pat. 1,258,885. See X.

Apparatus for drying and deodorising night soil, slaughter house refuse, and analogous materials. Eng. Pat. 114,700. See XIXb.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coke-ovens; Chemical problems at [ammonia-recovery plants in connection with] —. G. A. Phillipson. Coke Oven Managers' Assoc., Apr. 27, 1918. Chem. Trade J., 1918, 62, 355–356.

The view is advanced that the formation of "rock salt" in the saturators is due in most cases to irregular working. In direct and semi-direct plants uneven distribution of the gas in the saturator favours the formation of "rock salt" at the quietest parts. In semi-direct plants the variation of temperature is a contributory cause, and the feed of liquor and steam to the still should be maintained as constant as possible. The scum of arsenious sulphide which forms when arsenical acid is used favours the development of "rock salt," but the author has been able to avoid this trouble, although for two years he has used an acid mixture 75% of which was arsenical. The acidity of the bath is allowed to fall during a shift from 20% at the start to 6%. Half an hour before the end the ammonia liquor feed to the still is stopped and steam allowed to flow through to the saturator, while the acidity of the bath is brought

up to 20% again. The scum of arsenious sulphide coagulates and is precipitated. When the feed of liquor is started again at the beginning of the next shift the sulphide is ejected with the first crop of sulphate crystals. This method of working also prevents accumulations of pitch. The use of arsenical acid has led to rapid destruction of the saturator curtain. In semi-direct plants it is desirable to introduce the feed of fresh acid and drainings at the same level as the serrations of the distributor. In general, the use of hot water is a great aid to the prevention of "rock salt."

—H. J. II.

Fuel oil from vertical retorts by carbonisation of cannel and coal. J. West. Gas J., 1918, 142, 133–134.

EXPERIMENTS have been made to see if the vertical retorts of gasworks could be adapted to fuel oil production by the carbonisation of cannel and coal. Trials at low temperatures (700° C. outside the retort) had given poor results in regard to yields of gas, oil, and ammonia, whereas the by-products are important when the coke is of low value. Satisfactory yields were obtained when the retorting temperature was raised to 1150°–1200° C., the temperature at the top of the retort being reduced and steam admitted at the bottom. Carbonisation of a low-grade cannel (ash 9.57%, volatile matter 30.35%, and moisture 2.90%) in Glover-West retorts at 1130° C. (outside) gave the following results: Throughput, 4.78 tons per 21 hours; gas make per ton, 11,180 cu. ft., of calorific value 541 B.Th.U.; tar oil (dehydrated) per ton, 20.9 gallons; ammonium sulphate per ton, 41 lb.; fuel oils per ton, 17 gallons. Similar results were obtained when coal was carbonised.—H. J. II.

Lubricating oils; Relation between viscosity and the chemical constitution of [mineral] —. A. E. Dunstan and F. B. Thole. Inst. Petroleum Tech., Apr. 16, 1918. [Advance proof.]

Viscosity is a function both of mechanical friction of molecule against molecule, and of resistance to deformation brought about by the mutual attraction of the molecules for one another. It must be therefore largely a constitutive property, the important variables being unsaturation, conjugation, and symmetry. Unsaturation has in general the effect of raising viscosity; the alternation of double and single linkings of carbon atoms has the same effect in a higher degree; a symmetrically-distributed molecule possesses a lower viscosity than one markedly unsymmetrical. A lubricant should have as low a viscosity as possible whilst possessing the necessary "body" to persist as a film between shaft and bearing. All the evidence goes to show that "body" and viscosity run closely parallel in the case of lubricating oils, but this does not apply to all liquids. It is proposed therefore to combine with viscosity the determination of surface tension by the measurement of the weight of a falling drop. If, as appears probable, heavy oils are iso-colloids, the disperse phase being a molecular aggregate suspended in a dispersion medium of simpler structure, then "body" may be merely the effect of the degree of dispersion exhibited by a particular oil. In no case has the chemical constitution of a component of a lubricating oil been established, but the chemical behaviour of these oils indicates that among the components are unsaturated hydrocarbons (possibly open-chain, but more probably naphthenic and polynuclear, or perhaps both types), saturated hydrocarbons (naphthenic and probably to some extent polynuclear, but not to any appreciable extent paraffinoid), and aromatic hydrocarbons (to an unknown and possibly a limited extent), together with small amounts of sulphur- and oxygen-containing compounds, the latter of

which can be isolated, and are probably the principal cause of gumming. It is the polynuclear naphthenes, above all the unsaturated components of an oil, which confer viscosity and "body." When crude petroleum is distilled, the tendency is for the lower fractions to be saturated, yielding good petrol and burning oil, whilst the higher fractions become more and more unsaturated. The wax is a survivor of the paraffin series, and is accompanied by large amounts of naphthenic saturated and unsaturated hydrocarbons. The unsaturated compounds constitute between 20 and 40% of most lubricating oils, and can be removed from the oil by agitation with concentrated sulphuric acid. The residual saturated hydrocarbon is invariably of a higher molecular weight, but lower in density and lower in viscosity, the acid having removed the chief lubricating components. A lubricating oil should therefore contain as large a proportion of unsaturated hydrocarbons as is compatible with not too great a susceptibility to oxidation, polymerisation, and gumming. Mineral lubricating oils have, however, very low iodine values, indicating low reactivity, a fact which is in keeping with the view that the unsaturated hydrocarbons are probably polynuclear and naphthenic in type. The tendency for these bodies to oxidise to gummy products is therefore very small, and probably it is the small amount (up to 3%) of oxygen-containing resinous matter which gives rise to gumming.—T. St.

PATENTS.

Pulverised fuel; Apparatus for burning — T. B. Cram, Assignor to The Railway Materials Co., Chicago, Ill. U.S. Pat. 1,258,654, Mar. 12, 1918. Date of appl., July 19, 1915.

A VERTICAL cylindrical combustion chamber of refractory material is provided with a superposed concentric conduit of smaller cross-section, arranged so that an abrupt shoulder is produced at the junction. The pulverised fuel is injected by a concentric nozzle at the upper end of the conduit, and air is supplied through the annular passage between the nozzle and the conduit. A limited combustion takes place in the conduit, and the shoulder causes the formation of eddies surrounding the fuel jet, thus mixing part of the fuel with the surrounding air and preventing backward propagation of the flame. The lower end of the combustion chamber terminates at one end of a horizontal chamber into which a further supply of air is delivered by a jet at the end.—W. F. F.

Finely-divided material [fuel] and air; Apparatus for mixing — A. G. Kinyon and A. I. Jacobs, Assignors to Powdered Coal Engineering and Equipment Co., Chicago, Ill. U.S. Pat. 1,258,912, Mar. 12, 1918. Date of appl., June 21, 1917.

POWDERED fuel is supplied from the hopper, 12, to the rotary helical conveyor, 14, which delivers it to the perforated mixing chamber, 8, surrounded by a casing, 3. The conveyor shaft carries also a perforated tube, 25, opening into the mixing chamber

and also into the casing, and a helical rib, 35, is mounted on the tube. Air under pressure is supplied to the casing at the inlet, 6, passes through the perforated tube to the chamber 8, where it is

mixed with the powdered material, and both are then delivered at the outlet, 7.—W. F. F.

Artificial-fuel composition and process. R. F. Dalton, New York. U.S. Pat. 1,260,286, Mar. 19, 1918. Date of appl., Jan. 12, 1918.

Loose anthracite coal dust or screenings, 1 ton, and a liquid fuel of low viscosity and high boiling point, 10 galls., are mixed together so that the surfaces of the coal particles are merely wetted and the interstices are not filled with the liquid. A substantial proportion of the liquid fuel remains in the mixture up to the ignition point of the coal. The mixture is delivered to the fire in loose condition.—W. F. F.

Coke ovens of the horizontal or approximately horizontal flue type. H. B. Porteous and P. T. Allen, Redcar, Yorks. Eng. Pat. 114,936, June 9, 1917. (Appl. No. 8269 of 1917.)

In a battery of coke ovens separated by walls containing heating flues, the air for combustion passes through a horizontal passage in the upper part of each dividing wall to the back of the oven, and thence down a vertical passage in the wall to a pair of return flues in the wall, below the oven floor level. The heated air then rises through a central passage in each wall communicating at intervals in its length with horizontal combustion chambers on each side of it within the wall. The fuel gas is supplied to the combustion chambers, and the burnt gases pass back again through horizontal flues in the wall similar to the combustion chambers and alternating with them. The burnt gases then pass downwards through a vertical flue at the front of the wall to a pair of horizontal flues, one under each of two adjacent ovens. The air flues mentioned above are between these horizontal gas flues, and the air is thereby preheated as it passes through them in the opposite direction to that of the gas. The hot gases finally pass to discharge flues in the base of the setting. The gas and air supplied to each flue may be regulated at the front of the ovens.—W. F. F.

Coke-oven foundation. A. Roberts, Evanston, Ill. U.S. Pat. 1,259,133, Mar. 12, 1918. Date of appl., Feb. 23, 1915. Renewed June 22, 1917.

A BENCH of coke-ovens is provided with a line of "sole blocks" beneath the ovens, supporting the carbonising chambers and the heating walls. Each block has a longitudinal opening and a transverse opening communicating with each other in the form of a Maltese cross. The spent gases pass from a passage at each side of the line of blocks through the transverse openings to the passage formed by the longitudinal openings in the blocks. Transverse tunnels are formed below each of the last-mentioned passages and communicate with them by vertical connections. The spent gases finally pass by downward passages from each end of the transverse tunnels to discharge tunnels below and at each side of the bench of ovens.—W. F. F.

Retorts or offtake pipes; Method of and means for equalising or maintaining an equilibrium or any predetermined condition of pressure in — in the manufacture of coal gas or in the volatilisation of other suitable substances. A. A. Macintosh, St. Kilda, Victoria, and W. H. Hunt, Melbourne, Australia. Eng. Pat. 105,563, Apr. 10, 1917. (Appl. No. 5037 of 1917.) Under Int. Conv., Apr. 3, 1916.

In an apparatus for maintaining the pressure in retorts for coal-gas manufacture, coke ovens, or other apparatus from which gas is liberated by volatilisation, the gas offtake passes downwards into a closed chamber, its outlet being below the surface of water maintained at a desired level. A dividing partition extends downwards from the top of the chamber into the water, and an outlet pipe for gas is provided in the top of the same compart-

ment which contains the inlet pipe. A flow of gas from the retort is induced by an exhauster connected to the outlet, the gas passing through the water. Water is continually supplied to the chamber and overflows from the second compartment by a vertical pipe extending upwards into it, the level of the top of the pipe being adjusted as desired by a screwed sleeve. The second compartment is open to the air. Heavy tarry material is withdrawn from the chamber by a pipe at the bottom.—W. F. F.

[Gas] retort settings; Regenerative —. Drakes Ltd., and W. A. Drake, Halifax. Eng. Pat. 114,859, July 30, 1917. (Appl. No. 1534 of 1917.)

In regenerative furnaces for heating retorts for the production of coal gas and the like, of the type in which the producer and regenerative flues are situated within the arch which supports a set of retorts, the hot gases from the producer at the front of the setting pass through a horizontal conduit to the back of the setting and then back through other horizontal conduits to a common chamber just behind the producer. The gases then pass through the regenerative passages to the back of the setting, and return to a transverse discharge tunnel behind the producer. The secondary air passes through transverse passages in the regenerator to longitudinal passages below and surrounding the hot gas conduit leading from the producer. These passages are connected in parallel in groups to common chambers at the back of the setting, the exit from each of these chambers being controlled by a damper. Other flues may be provided so that part of the secondary air may be conducted to the space below the grate in the producer.—W. F. F.

Gas producing and consuming plants. H. A. Drefflein and M. S. Fihn, Chicago. Eng. Pat. 114,474, Apr. 4, 1917. (Appl. No. 4873 of 1917.)

In an apparatus in which a flow of gas from a producer is induced and burnt by a jet of air, the air nozzle shown in the diagram is placed in the conduit leading to the burner nozzle. The inner tapered tube, 19, is closed at its rear end by a disc, 21, provided with equally spaced sector shaped openings, 22. A collar, 23, fitting the annular space between the tube, 19, and the outer sleeve, 17, is also provided with openings which are angularly between the openings in the disc, 21, and of equal area. A valve member, 26, is mounted on a spindle, 31, which can be operated externally by hand, and has projecting radial sectors which are adapted to

close either the outer or inner set of openings. The maximum flow of gas is induced when the openings, 22, are wide open, and complete closing of the openings, 23, is prevented by a stop so that a small flow of air takes place. This is obstructed by the lugs, 29, and by the collar, 30, thus producing eddies, so that back flow of gas and deposition of carbon are prevented. When the openings, 22, are closed, and 23 are open, the greater diffusion of the air jet induces a smaller flow of gas. In a modification, the nozzle is provided with peripheral openings only and fits closely into the surrounding tube, and a varying induction of gas is produced by moving the nozzle to and from the outlet of the surrounding tube.—W. F. F.

Sulphate of ammonia; Process and apparatus for the recovery of — from producer gases. F. Mellor, Glasgow. Eng. Pat. 114,658, Apr. 11, 1917. (Appl. No. 5093 of 1917.)

PRODUCER gas is passed through a mechanical washer throwing a minimum of back pressure, to remove dust, and then passed at a temperature of 95°–105° C. through a second mechanical washer through which liquor containing 3% of sulphuric acid is circulated. The gas is scrubbed by suitable rotating paddles, the liquor becomes saturated, and ammonium sulphate crystals are deposited in wells in the bottom of the washing tank. The crystals are discharged periodically and dried in centrifugal dryers, the discharge outlet from each well to the dryers being controlled by a valve. A tar separator may also be connected to the washer by a trapped pipe, and the liquor circulated through it.—W. F. F.

Explosive gaseous mixtures; Apparatus for burning —. C. E. Lucke, Assignor to Gas and Oil Combustion Co., New York. U.S. Pat. 1,259,029, Mar. 12, 1918. Date of appl., May 20, 1913. Renewed July 28, 1917.

The explosive gaseous mixture passes from a supply chamber through a large number of passages formed by partitions arranged so that the passages are sufficiently narrow to prevent backward propagation of the flame. The passages and supply chamber are cooled by a cooling device intersecting the partitions, and the mixture, which leaves the passages with a velocity greater than that of flame propagation, is reduced in velocity and burnt in a porous refractory medium.—W. F. F.

Petroleum; Process for refining —. M. J. Trumble, Los Angeles, Cal., Assignor to Simplex Refining Co. U.S. Pat. 1,259,171, Mar. 12, 1918. Date of appl., Sept. 27, 1909.

PETROLEUM is introduced successively into a series of bodies of water, and a heating medium is also introduced so as to heat the successive bodies of water to progressively higher temperatures, and to agitate the mixture of oil and water to produce an emulsion. The vapours produced at each temperature are condensed separately, and the residuum is removed from the last body of water.

—L. A. C.

Hydrocarbon oils; Apparatus for the treatment of —. R. Seeger, St. Louis, Mo., Assignor to New Process Oil Co. U.S. Pat. 1,259,786, Mar. 19, 1918. Date of appl., Sept. 23, 1916.

The apparatus consists of two chambers, the first containing a cracking retort, and the second, which is heated by gas issuing from the first chamber, having means for generating steam which passes to the cracking retort. Spaced outlets enable the heat in the second chamber to be controlled so that the temperature of the steam does not exceed 250° F. (about 120° C.). A chimney is connected with both the top and the bottom of the second chamber.—L. A. C.

Petroleum and the like; Method of and apparatus for distilling —. L. O. Sherman, East Chicago, Ind., Assignor to The Cleveland Trust Co., Cleveland, Ohio. U.S. Pat. 1,260,584, Mar. 26, 1918. Date of appl., Apr. 24, 1916.

CRUDE petroleum is heated under pressure in a still to 650°–850° F. (about 340°–450° C.). The vapours are condensed under pressure in two portions, and the portion of higher boiling point is led through a pipe immersed in a false bottom of lead in the still. The vapours thus produced pass into the vapour space of the still.—L. A. C.

[Hydrocarbon] oils; Process of distilling and cracking —. J. A. Swaton, Los Angeles, Cal. U.S. Pat. 1,260,731, Mar. 23, 1918. Date of appl., Aug. 20, 1917.

HYDROCARBON oils are distilled at a progressively rising temperature and the vapours led off to a cracking zone maintained at a temperature 100°–400° C. higher than the distilling zone. The heavier hydrocarbons are separated from the lighter.

—L. A. C.

Gasoline; Process for making —. F. C. Devericks, Assignor to L. S. Hornor, Clarksburg, W. Va. U.S. Pat. 1,260,970, March 26, 1918. Date of appl., Aug. 3, 1915.

From the product obtained by condensing casing-head natural gas, a hydrocarbon oil of approximately 85° B. (sp. gr. 0.651) is recovered. A portion of the uncondensed gas is absorbed in low-grade oil, thereby raising the gravity of the oil. The resultant oil is mixed with the hydrocarbons of 85° B., to produce a homogeneous liquid of approximately 70° B. (sp. gr. 0.700).—L. A. C.

Cementitious bituminous emulsion. W. M. Fraser, Woodbridge, N.J., Assignor to The Barber Asphalt Paving Co., Philadelphia, Pa. U.S. Pat. 1,259,223, Mar. 12, 1918. Date of appl., Oct. 25, 1917.

ABOUT 75 galls. of a semi-liquid asphaltic residuum and about 43 galls. of an aqueous solution of rosin or rosin oil soap are mixed together until thoroughly emulsified and miscible in all proportions with water. The emulsion will not separate into its components within thirty days, and when tested with a drop of water is stained a light brown colour at the point of contact.—L. A. C.

Apparatus for bringing liquids and gases, vapours, fumes, and the like into intimate contact. Eng. Pat. 115,000. See I.

Processes and apparatus for obtaining lower from higher carburets of hydrogen [hydrocarbons]. Eng. Pat. 108,454. See III.

Process of making cyanide. U.S. Pat. 1,259,702. See VII.

Process of manufacturing lampblack [and hydrochloric acid, from natural gas]. U.S. Pat. 1,259,121. See XIII.

Process of preserving bagasse, etc., and making fuel therefrom. Process for economic steam production in cane-sugar factories. U.S. Pat. 1,258,888 and 1,258,889. See XVII.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Destructive distillation of birch; Effect of incomplete distillation on the yield of products in the —. R. C. Palmer, J. Ind. Eng. Chem., 1918, 10, 260–262.

WHEN insufficiently seasoned or excessively wet wood is distilled, it is difficult to complete the distillation within 24 hours, and the proportion of incompletely charred pieces ("brands") is then large (8 to 10%). These brands are usually redistilled. In experiments in which yellow birch cord wood was distilled at about 340° C. in a retort taking a charge of 50 lb., one set of distillations was carried out to completion, whilst others were interrupted at definite points, and the brands made to absorb 33% of moisture and then redistilled. By stopping the distillation at the point when 10% of brands was present, the loss of wood alcohol was about 5% and that of acetate of lime 2.5%. The results also showed that formic acid is formed more rapidly than acetic acid, the total yield of the

former being obtained when about half of the wood remains as brands. Tar soluble in the pyroligneous acid is the next volatile product to be formed, and this is followed by the wood alcohol, and then by the oily tar which separates from the pyroligneous acid. In order to obtain the maximum yield of wood alcohol it is necessary to control the temperature of distillation just before the formation of the tar. The total yield of formic acid was about 30% higher, that of the acetic acid about 2.4% lower, the alcohol about 2.8% higher, the tar 20–25% lower, and the charcoal about 4% higher in the double distillation.—C. A. M.

Destructive distillation of hard wood; Influence of moisture on the yield of products in the —.

R. C. Palmer and H. Cloukey, J. Ind. Eng. Chem., 1918, 10, 262–264.

CORR wood from beech, yellow birch, and hard maple, which had been seasoned for about 18 months, and similar wood seasoned for 4 to 6 months, were destructively distilled in a laboratory retort taking a charge of about 50 lb. In the uncontrolled distillations the maximum heat was maintained until the distillates showed a considerable proportion of tar, and the distillation then finished largely by means of the exothermic reaction; whilst in the controlled distillations the heat was checked on the first indications of tar, and then regulated so that the rate of rise of temperature was lower than in the uncontrolled distillations. It was found that moisture has a favourable influence on the yield of acetic acid when the distillation is thus controlled. In the case of beech and maple the best yields of acetic acid under these conditions are obtained from wood which has only been moderately seasoned. About 15% more was obtained from wood seasoned only for 6 months than from that seasoned for 18 months. In the case of birch, however, there is little difference in the results given by wood seasoned for the two periods. For the production of formic acid the best yields are obtained by the rapid (uncontrolled) distillation of wet wood, especially in the case of beech. An excess of moisture also tends to increase the yield of wood alcohol from beech, and to a less extent from maple, in uncontrolled distillation, but in the case of birch and of maple in controlled distillations the dry wood gives the highest yields of alcohol. As a rule the yields of tar and charcoal are increased by the presence of moisture, except in the case of beech for tar and of birch for charcoal.—C. A. M.

Destructive distillation of hard woods; Effect of catalysts [phosphoric acid] on the yield of products in the —. R. C. Palmer, J. Ind. Eng. Chem., 1918, 10, 264–270.

WOOD chips were impregnated with aqueous solutions of phosphoric acid, and destructively distilled. The yield of acetic acid was thus greatly increased, e.g. from 5.13 to 13.85% in one experiment in which 2.45% of catalyst was added. The presence of the phosphoric acid also increased the yield of wood alcohol, in some experiments by 40 to 90%. Distillation of mixtures of wood and tar under pressure showed that the methoxy groups can be readily split off, with the formation of methyl alcohol. In one distillation under a pressure of 90 lb., about 20% of the theoretical yield of methyl alcohol was obtained. The metaphosphoric acid in the residue of charcoal could probably be quantitatively recovered by leaching. The use of a mixture of phosphoric acid and creosote as catalyst did not increase the yields of methyl alcohol, whilst sulphuric acid, as claimed in Ger. Pat. 185,934, reduced the yields of formic and acetic acids and prevented the formation of any methyl alcohol.

—C. A. M.

Vegetable decolorising carbons [for sugar refining].
Schneller. See XVII.

PATENTS.

Wet carbonising apparatus and process [for peat].
W. H. Boorne, London. Eng. Pat. 114,603,
Dec. 22, 1917. (Appl. No. 19,019 of 1917.)

The apparatus comprises two horizontal tubes held together by a coupling, part of which forms a bracket inside the tube. Around part of the first tube is an annular space into which the peat is introduced, and from which it travels by an external pipe to the far end of the second tube. Within this tube is a steel casing capable of rotation, having its innermost end supported by the bracket. There is an annular space between the casing and the tube, the outer end of the space being closed by a bush. Fins arranged spirally on the outside of the casing impart a rotary motion to the peat as it passes through the annular space, which is heated both internally and externally by steam, there being a steam jacket around the tube. Leaving the annular chamber through openings in the bracket, the peat passes into the first tube, where it pre-heats the peat fed into the annular space around this tube, and leaves the apparatus through a spring-controlled valve.—L. A. C.

Carbonaceous materials; Destructive distillation of
— F. M. Perkin, London, and J. West, Southport. Eng. Pat. 114,337, June 11, 1917. (Appl. No. 8337 of 1917.)

Is the continuous distillation of carbonaceous material, e.g., coal, in vertical retorts at high temperatures, a higher yield of coal tar and of aromatic hydrocarbons of lower boiling point, and a smaller yield of aliphatic hydrocarbons, is obtained by reducing the period of low-temperature distillation to a minimum. An inert gas such as stripped coal gas or producer gas is passed into the lower end of the retort at such a rate that it becomes highly heated in passing through the red-hot coke in the lower part of the retort. The hot gas carries off volatile matter from the partly coked zone, and finally passes through the cooler zone at the top where heat is given up, but not sufficiently to cause condensation of the volatile matter on the coal. The gas and distillates are then drawn off through a discharge conduit at the top of the retort.—W. F. F.

Coal; System of carbonising — J. A. Yeadon and T. Whitaker, Leeds. Eng. Pat. 114,971, Sept. 24, 1917. (Appl. No. 13,694 of 1917.)

Is a process for the continuous carbonisation of coal (including lignite, cannel, shale, peat, and analogous materials) the coal is very finely ground and is fed continuously from a hopper by a horizontal screw conveyor into the top of a retort. The screw does not extend to the edge of the retort, so that the opening is always sealed by a mass of fine coal filling the conduit. The retort is heated uniformly, and the coal falls freely through it so that it is continuously and instantaneously carbonised. The fine coke is discharged at the bottom of the retort by a similar screw conveyor, the discharge conduit being similarly sealed by a mass of powdered material.—W. F. F.

Wood; Method of destructively distilling — R. C. Palmer, Pensacola, Fla., Assignor to Govt. and people of U.S.A. U.S. Pat. 1,259,277, Mar. 12, 1918. Date of appl., March 23, 1917. (Dedicated to the public.)

Wood is intimately mixed with a solution of orthophosphoric acid, and any excess water removed by evaporation. The mixture is then heated in a retort to a temperature yielding the maximum amount of acetic acid and methyl alcohol, the vapours being

confined until they attain a pressure not exceeding 300 lb. per sq. in., and then allowed to escape under pressure to a condenser.—L. A. C.

Electrode for luminous arc electric lamps and process of making the same. F. Buchanan, Syracuse, N.Y. U.S. Pat. 1,258,981, Mar. 12, 1918. Date of appl., June 19, 1911.

About 12 lb. of dry pulverised rutile is mixed intimately with the unevaporative residue of 1 quart of water-glass to form a plastic mass, the water of the moist mass is evaporated, the dry product pulverised, and then filled into an electric conducting shell of metal, such as iron, about $\frac{1}{8}$ " in thickness, the shell being of sufficient substance to carry the current to supply a conductive metal at the arc during the consumption of the electrode, and to render the fused end of the conductor conductive when cold.—B. N.

Carbon and method of manufacturing same. R. D. Pike, Richmond, Cal. U.S. Pat. 1,262,251, Apr. 9, 1918. Date of appl., Dec. 21, 1915.

See Eng. Pat. 102,645 of 1916; this J., 1917, 127.

III.—TAR AND TAR PRODUCTS.

Benzol; Rectification of — J. D. Hamer, Coke Oven Managers' Assoc., Apr. 27, 1918. Chem. Trade J., 1918, 62, 359.

The steam-heated still as commonly used, in which the temperature of the wash oil falls in its passage through the system, is considered wasteful and irrational compared with the newer types in which the oil is heated by steam coils on the trays. In normal plants, the temperature of the oil after the pre-heater should be within 10° C. of that of the steam. The quality of the crude benzol is regulated by the quantity of live steam used and the dephlegmating devices, which should be capable of regulation independently of the heat exchangers, and should not return their condensed products to the wash oil in the still. Wash oils should not dissolve any appreciable quantity of water. Economy of acid may be effected by separating the "once run" benzol into three fractions prior to washing if the carbon bisulphide and unsaturated compounds have been largely removed by a slow and careful distillation of the fore-runnings. Chlorine reacts selectively with the thiophenes. If chlorine sufficient to combine with the thiophene and thiotolene be used these are preferentially chlorinated and the chloro-derivatives are so much less volatile than the benzene and toluene that a separation by distillation can be readily effected. (See also this J., 1918, 173 B.)

Sulphite turpentine. Schorger. See V.

PATENTS.

Carburets of hydrogen [hydrocarbons]; Processes and apparatus for obtaining lower from higher

— J. Oltmans, Hilversum, Holland. Eng. Pat. 108,451, Jan. 2, 1917. (Appl. No. 54 of 1917.) Under Int. Conv., Aug. 1, 1916.

HIGHER hydrocarbons are converted into lower hydrocarbons, e.g., coal tar or coal tar oil to benzol, petroleum to benzine, etc., by vaporising the oil and mixing the vapour with steam at 5–6 atmos., thorough admixture being ensured by passing the mixed vapours through a zig-zag length of pipework. The vapours then pass through a mass of coal or coke previously brought to incandescence by ignition in a current of air. The products of reaction pass through a scrubber, and are then mixed with a further quantity of steam and pass into a condenser. The aqueous portion of the condensed liquid is separated and the remainder purified by distillation.—L. A. C.

Anthraquinonesulphonic acids; Process of making salts of —. E. G. Griffin. Cliffside, N.J., Assignor to The Barrett Co. U.S. Pat. 1,260,535, Mar. 26, 1918. Date of appl., Mar. 22, 1917.

Sodium sulphate is added to a solution containing anthraquinonemonosulphonic and disulphonic acids and the comparatively insoluble sodium anthraquinonemonosulphonate filtered off. The anthraquinonedisulphonic acids are recovered from the filtrate.—L. A. C.

Benzenesulphonic acid and alkali benzenesulphonate; Production of —. J. W. Aylsworth, deceased, by A. M. Aylsworth and Savings Investment and Trust Co., East Orange, N.J. U.S. Pat. 1,260,852, Mar. 26, 1918. Date of appl., Jan. 23, 1917.

Excess of benzene is heated in a closed apparatus with sulphuric acid, the temperature at first being kept at 70° C., and then raised to approximately 120° C. after a number of hours. The mass is cooled below 70° C., and sufficient sulphuric anhydride added, with stirring, to convert the water of reaction into sulphuric acid. The mixture is heated as before, and the process repeated if necessary.

—L. A. C.

IV.—COLOURING MATTERS AND DYES.

Hamatoxylin africanum. A. G. Perkin. J. Soc. Dyers and Col., 1918, 34, 99.

A SOUTH AFRICAN species of *Hamatoxylin* was discovered in 1909 in Great Namaqualand, and consists of a shrub 1–1.5 m. in height, with yellow flowers and smaller leaves than *H. campechianum*. Stems 0.5–1.25 in. in diameter consist mainly of a reddish-brown core surrounded by a nearly colourless layer of wood; this core, as in the case of logwood also, darkens on exposure to air. The colour reactions of the extract resemble those of Brazilwood rather than those of logwood; it gives a brown with ferric chloride, not a black, and a pale pink precipitate with lead acetate, not a blue. Dyeing trials with *H. africanum* on mordanted wool show colours similar to those obtained with Brazilwood, but in all cases duller in shade and poorer in the red constituent. On this account it is of no technical importance. The slight difference in dyeing properties of *H. africanum* and Brazilwood may be due to impurities present in the former, but, on the other hand, it might be expected that a methyl ether of hamatoxylin would dye shades almost identical in character with those of brazilin itself.

—J. F. B.

PATENT.

Chlorinated products of xylene and new compounds and [triphenylmethane] dyestuffs therefrom; Manufacture of —. R. B. Ransford, London. From L. Cassella and Co., Frankfurt, Germany. Eng. Pat. 114,645, Mar. 12, 1917. (Appl. No. 3609 of 1917).

SEE U.S. Pat. 1,219,166 of 1917; this J., 1917, 500.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Yellow pine chips; Experiments on the pulping of extracted — by the sulphate process. O. Kress and C. K. Textor. J. Ind. Eng. Chem., 1918, 10, 268–270.

LONGLEAF pine chips from which the rosin and turpentine have been extracted are at the present time a waste material used for fuel. In experiments to determine the suitability of the extracted chips for the manufacture of "Kraft" paper, the material was coarsely screened and treated in an upright steel digester similar to that used in the ordinary

pulping process. The yield of crude pulp ranged from 35.3 to 43.8%, but it would be possible to increase this considerably by efficient screening of the chips. The oil condensed from the gases leaving the digester amounted on the average to 2.3 galls. of oil per ton of dry chips. The strength of the paper made from the pulp was lower than that of paper prepared from longleaf pine round wood, this being attributed partly to the small size of the chips, and partly to overheating in the preliminary treatment to remove the rosin and turpentine.

—C. A. M.

Sulphite turpentine. A. W. Schorger. J. Ind. Eng. Chem., 1918, 10, 258–260.

THE oil which collects on the surface of the liquid in the separator used in recovering sulphur dioxide in the manufacture of wood pulp is known as sulphite turpentine. It varies in colour from yellow to black, and is often impregnated with sulphur dioxide. From 0.36 to 1 gall. of this turpentine is obtained per ton of pulp derived from spruce or balsam, but hemlock does not yield this by-product. The present annual production of sulphite pulp in U.S.A. and Canada exceeds 1,500,000 tons, and assuming that only 0.5 gall. per ton was recovered, the annual yield of turpentine from this source should be about 750,000 galls. As was pointed out by Herty and Graham (this J., 1914, 1073), sulphite turpentine is mainly composed of cymene. The following results were obtained in the distillation of the oil from three different mills:—

Composition of wood.	Up to 175° C.	175°–176° C.	176°–177° C.	177°–178° C.	178°–182° C.	Residue.
%	%	%	%	%	%	%
Spruce, 100 ...	1.11	7.76	84.63	—	—	6.65
Spruce, 90 } Balsam, 10 }	7.66	15.18	39.00	33.66	—	3.74
Spruce, 65 } Balsam, 35 }	0.43	2.37	22.00	19.00	35.00	8.81

These results indicate that the highest yield of cymene is obtained when spruce is used as the raw material. Cymene from this source can be used in the production of toluene (see Schorger, J. Amer. Chem. Soc., 1917, 39, 2671; and Rittmann, Fr. Pat. 179,786 of 1915; this J., 1916, 1103). By fusing the sodium salt of the 2-sulphonic acid of cymene with alkali at about 300° C., dissolving the mass in water, and acidifying the solution and distilling it with steam, carvacrol was obtained, but the yields under laboratory conditions were very small, probably owing to the difficulty of controlling the temperature. (See also J. Chem. Soc., June, 1918.)

—C. A. M.

PATENTS.

Textile materials or the like; Waterproofing compositions for —. J. D. Williams, Rhyl. Eng. Pat. 114,494, Apr. 17, 1917. (Appl. No. 5406 of 1917.)

THE fabrics are treated with a composition consisting essentially of gum tragacanth associated with lead acetate and aluminium sulphate together or separately, to which may be added gold size, terebene, soap, and other ingredients.—J. F. B.

Cellulose [wood pulp] and like fibrous materials; Apparatus for washing and airing —. A. D. Berglund, Gulslogen, Norway. Eng. Pat. 114,453, Mar. 23, 1917. (Appl. No. 4248 of 1917.)

FOR washing and airing cellulose to free the mass from chemicals and gas after bleaching, the pulp is introduced into a tub the bottom of which slopes

towards the middle from both sides, and from one end towards a gutter, which communicates through a valve with a centrifugal pump. The tub is provided with a stirring device mounted longitudinally, and water is sprayed into the mass from sprinklers arranged above it and others which pass nearly to the bottom of the tub. The centrifugal pump delivers the pulp up a vertical pipe from which it is discharged over a spreading device and collects in a vessel which serves as an aerating apparatus. As it falls from the spreading device it comes in contact with air from a blower delivering the air through perforations below the pulp discharge orifice. From the aerating vessel it flows down a pipe to a distributing box, whence it is returned to the washing tub. The walls of the latter are lined with perforated filter tiles through which water escapes from the pulp.—J. F. B.

Viscose; Process for the production of articles from —. B. Borzykowski, Cleveland, Ohio. U.S. Pat. 1,260,508, Mar. 26, 1918. Date of appl., May 29, 1917.

FRESH viscose solution is passed through an extended path in a precipitating bath having a density above 18° B. (sp. gr. 1.134) and containing less than 10% of sulphuric acid or the equivalent amount of other acids.—J. F. B.

Paper; Coated —. H. R. Rafsky, Portland, Me. U.S. Pat. 1,260,448, Mar. 26, 1918. Date of appl., Dec. 11, 1915. Renewed Aug. 13, 1917.

The surface of a body paper is coated with "lime mud," ground to a uniformly fine state of division and containing a small amount of an alkali and an adhesive, such as casein, soluble in such alkali.

—J. F. B.

Paper; Method and apparatus for drying coated —. C. F. Pease, Assignor to The C. F. Pease Co., Chicago, Ill. U.S. Pat. 1,260,570, Mar. 26, 1918. Date of appl., Mar. 6, 1917.

The coated paper is first passed through a chamber containing combustion gases and hot air, and then through a chamber in which hot air is circulated. The apparatus consists of an entrance chamber containing a bank of heating tubes and communicating with the combustion gases chamber, an air heating chamber with several heaters, a conduit for combustion gases surrounding the air heating chamber and communicating with the entrance chamber, a transverse chamber communicating with the hot air chamber and the air heating chamber, and provided with means to increase the flow of combustion gases through the conduit.—J. F. B.

Process of producing artificial leather. U.S. Pats. 1,257,665 and 1,257,736. See XV.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

PATENTS.

Cotton fabrics (tissues, yarns, and embroideries); Process for imparting new properties [transparent effects] to —. Heberlein & Co. A.-G., Wattwil, Switzerland. Eng. Pat. 108,671, July 1, 1917. (Appl. No. 9666 of 1917.) Under Int. Conv., Aug. 11, 1916.

The material is treated with a solution of caustic alkali of a density above 20° B. (sp. gr. 1.15) at temperatures below 0° C. (e.g., -10° C.) until it acquires a transparent appearance which is not lost after washing and drying. Increased transparency is obtained by subjecting the treated fabric to the action of sulphuric acid of a density about 50.5° B. (sp. gr. 1.50), which may be cooled below 0° C. in

order to obtain a slower action. The treatments with alkali and acid may be repeated alternately until a sufficient effect is obtained. If desired, pattern effects may be produced by local treatments or by the use of a reserve.—J. F. B.

Fabric pieces; Process and plant for the treatment of —. [Weighting of silk goods.] F. J. B. Kuibichler and A. Fankhauser, Emmetbaden, Assignors to Wegmann & Co., Baden, Switzerland. U.S. Pat. 1,259,526, Mar. 19, 1918. Date of appl., Nov. 25, 1916.

SILK piece goods are prepared for the weighting treatment by forcing a liquid through the fabric rolled upon a metal drum, the drum is transferred to a drying machine, and the prepared fabric dried by centrifugal action. The fabric is then wound off the metal drum and rolled up on an acid-proof drum while it is simultaneously treated with stannic chloride; the acid-proof drum, together with the fabric, is placed in a bath of stannic chloride, then transferred to the drying machine, where the fabric is again dried by centrifugal action. The fabric is then unwound from the drum in a washing machine and again wound up on a metal drum, passing through a washing treatment on the way, after which it is dried by centrifugal action as before. The material is repeatedly treated with phosphate and stannic chloride until the desired charge of loading is fixed upon the silk.—J. F. B.

Dyeing machines. H. M. Dudley, Philadelphia, Pa. U.S. Pats. (A) 1,259,839 and (B) 1,259,840, Mar. 19, 1918. Dates of appl., (A) Mar. 29 and (B) Mar. 31, 1917.

(A) A hollow reel, comprising non-perforated flanges extending outwards and connected by a perforated body, revolves within a receptacle. A foraminous member, which may be constructed of a series of "upwardly and downwardly extended pyramids," with passages for liquid through them, surrounds the perforated body and is spaced therefrom. Fabric to be dyed is wrapped around this foraminous member and enclosed by a foraminous belt of similar construction, capable of being tightly adjusted around the fabric. A series of tubes connects the inner face of the perforated body with a source of liquid supply from opposite ends of the reel, and means are provided within the tubes for breaking up and distributing the flow of liquid equally over the inner face of the body, the tubes and distributing means being integral with the reel and revolving therewith. Liquid or air is forced through the reel and through the fabric while the reel is in motion and is returned from the dyeing chamber into circulation. (B) The machine consists of a receptacle having non-perforated sides, a fixed foraminous plate extending across the receptacle and integral with the sides, and a similar movable plate above the first, these plates being composed of a series of pyramidal bars with openings between them for the passage of a liquid. A second receptacle connects the first with a source of liquid supply, and serves to secure an even pressure and distribution of the liquid on the lower face of the fixed foraminous plate, and an overflow pipe from the first receptacle above the movable foraminous plate conducts the liquid back to the second. In the liquid-chamber below the fixed plate is a member having its ends converging upwards and downwards, and this liquid-chamber is connected by a pipe with the liquid-chamber of a smaller vessel of similar construction, which serves as a testing vessel. Means are provided for circulating the liquid through both vessels simultaneously, for heating the liquid as it passes through the larger vessel, and for interrupting the flow through the smaller vessel for testing purposes, while continuing the flow through the larger one.

—J. F. B.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Nitric acid; Production of — from nitrogen oxides. G. B. Taylor, J. H. Capps, and A. S. Coolidge. *J. Ind. Eng. Chem.*, 1918, **10**, 270—275.

LABORATORY experiments showed that by absorbing nitrogen peroxide in sulphuric acid containing chromic acid, nitric acid was produced directly, and when the absorbing liquid was maintained at 150° C., the mist emitted consisted of 95 to 100% HNO_3 . The drawbacks to this process are the necessity for a hot absorbent and for the electrolytic recovery of chromic and sulphuric acids from the chromium sulphate. Attempts to prepare a strong mixed acid by electrolysis of solutions of nitrogen peroxide in strong sulphuric acid were unsuccessful owing to the efficiency of the process falling to a very low value as the concentration of the nitric acid in the solution increased. In experiments to determine the most suitable conditions for absorption of nitrogen oxides by water, the apparatus consisted of an ammonia saturator for producing a mixture of air and ammonia, an oxidiser for producing nitric oxide, a cooler composed of sets of U-tubes immersed in running water, and five stoneware towers, the first of which—the "oxidation tower"—was empty, whilst the others were packed with coke, leaving a reaction space of 1.9 cub. ft. at the top of each tower. The coke in each tower was flooded at intervals of about 30 mins. with 40% nitric acid. The results indicated that the absorption should be carried out at as low a temperature as possible. Artificial cooling of the air space in the oxidation tower would be advantageous. So long as the proportion of oxygen is kept near the theoretical requirement there is no pronounced increase in the loss of acid, but it is advisable not to allow the oxygen in the exit gas to fall below 5%. The oxidation tower and first two absorption towers absorb about 85% of the acid and the last two about 10%, and it is improbable that even doubling the number of towers would enable the last 5% to be recovered. Calculated on the basis of 90% efficiency and 10% of ammonia in the mixture supplied to the oxidiser, it would be necessary to have 25% additional air after oxidation to secure 5% of oxygen in the exit gas, and it would be preferable to introduce this before the mixture enters the reaction space before the first absorption tower. The experimental plant had the following capacity calculated on the basis of 0.285 grm. HNO_3 per litre of nitrogen:—

Cub. ft. of gas per min.	1.25	2.5	4.0
Efficiency of absorption, % . . .	98	95	91
HNO_3 recovered in 24 hours, lb. .	23	44.5	68

Part of the loss of acid is attributable to the formation of a non-absorbable acid mist. By placing a Cottrell precipitator between the third and fourth towers, the mist could be reduced to about 0.5%. The precipitator consisted of a $\frac{3}{4}$ in. glass tube having in the middle a platinum wire connected with the anode of a "kenotron" high-tension current rectifier, whilst a coil of copper wire was wrapped round the tube and connected with the inner wall by means of platinum wire. The acid recovered from the precipitator was 15 to 25% nitric acid with very little nitrous acid. The formation of the mist was found to be promoted by increasing the velocity of the gas, reducing the excess of oxygen, and by increase of the strength of acid in the third tower. The controlling reaction in the process is:—

and in order to allow sufficient time for this reaction as much space as possible should be given. Removal of packing material from the towers and the substitution of liquid sprays would increase the

oxidation space, whilst the use of the Cottrell precipitator would prevent loss of acid through the increase of mist thus produced. (See also *J. Chem. Soc.*, 1918, ii., 196)—C. A. M.

Formic acid and hydrosulphites: New reaction of —. E. Comanducci. *Boll. Chim. Farm.*, 1918, **57**, 101—102.

THE reddish-yellow coloration developed when formic acid or a liquid containing it is heated gently with concentrated sodium bisulphite solution (this *J.*, 1904, 1116) cannot be detected when the original solution is coloured. In this case the heating with the bisulphite is continued until gas-bubbles begin to escape, the liquid being then cooled and treated with a fresh, dilute sodium nitroprusside solution. A more or less intense green or blue coloration is produced according to the amount of formic acid present, hydrogen cyanide being evolved at the same time; the reaction is more sensitive if the nitroprusside solution is poured gently on to the other so as to form two layers. The composition of the blue precipitate corresponds with the formula $\text{Na}_2\text{Fe}_2(\text{CN})_6$. In this reaction, the formic acid reacts with the sodium bisulphite yielding sodium hydrosulphite, this giving the blue coloration with the nitroprusside.—T. H. P.

Potash in the Pintados Salar, Tarapacá, Chile. H. S. Gale. *Eng. and Min. J.*, 1918, **105**, 674—677.

THE Pintados Salar is one of the larger saline deposits in northern Chile. There is about 20 sq. miles of a hard rugged crust in the central or lowest part of the Salar surface which gradually changes outwards to a soft, crumbling deposit. The hard, rugged, weathered crust is the richer, potash-bearing portion of the Salar, the percentage of potassium present varying from nearly 3% up to about 7%, which exists in the form of glaserite; it consists largely of sodium chloride. Underlying the hard deposit is a loose granular deposit made up largely of glauberite, or in some places of gypsum.—W. G.

Potassium salts: Extraction of — from the Pintados Salar. R. C. Wells. *Eng. and Min. J.*, 1918, **105**, 678—679.

A LABORATORY method for the extraction of the potash salts from the Pintados Salar (see preceding abstract) is described as follows. The crushed saline material (100 grms.) is heated with 37 c.c. of water at 166° C. for 15 mins., with constant stirring, and then drained in a centrifuge and washed twice with 5.5 c.c. of hot water. The extract may be evaporated to dryness and the residue used as crude potassium salt (composition see column IV.) or the extract may be cooled to room temperature and the crystalline deposit separated (composition see column V.). The salts left in the mother liquor have the composition shown in column VI. and would be utilised again in a continuous process.

I.	II.	III.	IV.	V.	VI.
K	5.0	63.5	18.3	23.4	16.1
Na	32.2	13.1	24.3	19.4	26.4
Cl	41.3	18.9	45.2	35.0	49.5
SO_4	17.3	12.3	12.2	22.2	8.0

Column II. shows the composition of the Salar salts used, and column III. the percentage of each constituent extracted. There is a suggestion that advantage might be taken of the interaction of sodium nitrate and potassium chloride to form potassium nitrate, the Salar salts and caliche being treated together by the usual nitrate process so as to produce a mother liquor rich enough in potassium nitrate to yield that salt by simple crystallisation.—W. G.

Lime; Deterioration of — on keeping. S. A. Woodhead. Analyst, 1918, 43, 161-163.

POWERED lime kept in a dry shed and turned frequently was converted to the extent of 43% into carbonate in 64 days; the same lime heaped outside and exposed to the air for 4 months was converted to the extent of 12% only. Lump lime stored in bags and protected from rain lost 28% of its calcium oxide in 4 months, whilst the loss in the same time amounted to 52% when the lump lime was heaped and exposed to the atmosphere. —W. P. S.

Carbon dioxide; Detection of — in the analysis of carbonates or oxalates. O. F. Stafford. J. Amer. Chem. Soc., 1918, 40, 622.

To detect the presence of carbon dioxide in the gaseous products of the action of acids on minerals, a glass tube is inserted into the mouth of the test-tube; this tube is drawn out to a capillary fine enough to cause a drop of the reagent (baryta water) to remain in it, and not too fine to prevent bubbles of the gas from being drawn upward through the liquid. To make the test the gas from the test-tube is drawn through the baryta water by aspirating at the top of the inserted tube. The method may be made roughly quantitative for traces of carbonates or oxalates. Two such capillaries are used; the material to be examined is placed in one, and the second tube containing a drop of baryta water inserted into the mouth of the first and sealed to it by means of "Khotinsky" cement. Then by aspiration a drop of 30% sulphuric acid is drawn on to the material and the gas generated drawn through the baryta water. In the case of oxalates, 30% sulphuric acid mixed with potassium permanganate is used. The turbidity produced in the baryta water is compared with turbidities produced similarly from known amounts of carbonates or oxalates. —J. F. S.

Cream of tartar; [Determination of] lead in commercial —. A. J. Jones. Chem. and Drug., 1918, 90, 47.

THE following methods yield accurate results for the determination of lead in cream of tartar which contains iron, aluminium, calcium phosphate, etc. *Direct method.*—Ten grms. of the sample is dissolved in 10 c.c. of hydrochloric acid (B.P., sp. gr. 1.052) and 20 c.c. of water, the solution is boiled, filtered, and the insoluble portion washed with 40 c.c. of hot water. The filtrate is treated with a small crystal of potassium iodide, boiled, cooled, and the liberated iodine is removed by the addition of N/10 thiosulphate solution, 3 drops being added in excess. After the addition of 1 c.c. of 2% hydrocyanic acid solution and 16 c.c. of concentrated ammonia, the mixture is boiled until it becomes practically colourless, then cooled, and diluted to 100 c.c. Seventy-five c.c. of this solution is now diluted to 100 c.c., sodium sulphide is added, and the coloration obtained compared with that of a standard prepared with the remaining 25 c.c. of the solution and containing a known amount of lead together with proportionate quantities of the reagents used in the test solution. *Ignition method.*—Five grms. of the sample is incinerated gently, the charred mass is digested with 50 c.c. of water, filtered, the insoluble portion washed, and ignited to a grey ash. This is treated with 4 c.c. of hydrochloric acid, the solution diluted with 8 c.c. of water, boiled, filtered while hot, and the filter washed with 30 c.c. of boiling water. To the filtrate is added a crystal of potassium iodide, and, after boiling, the iodine is removed by the addition of N/10 thiosulphate solution. The solution is then boiled with the addition of 2 c.c. of 2% hydrocyanic acid solution and a slight excess of

ammonia, cooled, acidified with hydrochloric acid, 5 c.c. of 20% tartaric acid solution is added, the mixture is rendered ammoniacal, diluted to 100 c.c., treated with sodium sulphide, and the coloration compared with a standard. —W. P. S.

Sodium cyanide. W. J. Sharwood. J. Ind. Eng. Chem., 1918, 10, 292-295.

FOR the past year cyanides have for the first time been sold on the basis of their cyanogen content, the purest technical sodium compound containing "sodium cyanide 96 to 98%" or "cyanogen 51 to 52%," whilst the old so-called "98% KCN" contained about 39% of cyanogen. Commercial fused sodium cyanide contains only a trace of potassium and not more than 2 to 4% of total impurities. It is largely prepared synthetically by heating sodium amide (produced by the interaction of ammonia and metallic sodium) with carbon. The most recent method of preparing it for the market is to cast it mechanically into egg-shaped cakes weighing 1 oz. For technical purposes the most convenient method of determination is to titrate the solution with N/20 silver nitrate solution (1 c.c.=5 mgrms. of commercial NaCN), with potassium iodide as indicator. The burette readings then also give directly "lb. per ton of solution." For the determination of sodium and potassium in mixed cyanides, in which chlorides and carbonates are the usual impurities, it is often practicable to evaporate the salt with hydrochloric acid, to ignite the residue gently, to weigh the mixed chlorides, and to titrate the chlorine in part of the residue. From these data the proportions of sodium and potassium may be calculated. Alkali sulphides may be detected by shaking the cyanide with fine lead carbonate suspended in water; or by dissolving it in a solution of silver nitrate containing less than 1 mol. AgNO₃ for 2 equiv. CN; or by dissolving it in mercuric chloride solution. In each case a black precipitate or dark coloration indicates the presence of sulphide. Sodium cyanide is not deliquescent, and is much more soluble than potassium cyanide. The concentration of dilute solutions may be approximately ascertained by means of the formula— $(\text{Sp. gr.} - 1) \times 200 = \text{Grms. NaCN per 100 c.c.}$ Strong solutions of sodium cyanide differ but little in stability from those of potassium cyanide; if anything, they are somewhat more stable. —C. A. M.

Alkali cyanide; Manufacture of —. S. Urano. Kogyō-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1917, 20, 1309-1340.

CALCIUM cyanamide containing 19% of nitrogen, when fused with sodium chloride and charcoal in a small iron crucible, gives 70% of the theoretical yield of cyanide. The following conditions were found to be most suitable:—A charge consisting of 100 parts of calcium cyanamide, 100 of sodium chloride, 50 of charcoal, and 30 of calcium carbide is heated uniformly, without contact with air, at 940°-959° C. for 5 mins., the maximum temperature being attained gradually and the charge cooled quickly. The product contains about 20% of sodium cyanide, which is extracted with water or with 50% alcohol. When water was used as the solvent the yield of cyanide was 40% of the theoretical and when alcohol was employed the yield was 70%. —J. F. B.

Sulphides; Oxidation of — with potassium iodate. R. S. Dean. J. Amer. Chem. Soc., 1918, 40, 619-620.

IN continuation of previous work (see this J., 1915, 608), it is shown that with a large excess of iodate, and hydrochloric acid of any strength sufficiently high to prevent the hydrolysis of the iodine chloride formed, the whole of the sulphur is quantitatively

oxidised to sulphuric acid according to the equation

The estimation is carried out as follows: A solution of hydrogen sulphide is treated with the requisite excess of potassium iodate solution and hydrochloric acid (3–6 N) and the excess of iodate estimated by means of a standard iodine solution. The method has also been applied to the estimation of lead sulphide: the freshly precipitated sulphide is introduced into the iodate solution, hydrochloric acid added, and the titration completed as before. The results in both cases agree to within 0.1% of the theoretical value.—J. F. S.

Magnesia-alumina-silica; The ternary system — G. A. Rankin and H. E. Merwin. *Amer. J. Sci.*, 1918, 45, 301–325.

The ternary system, magnesia-alumina-silica, has been investigated thermally to determine the melting temperatures of the various phases, and microscopically to identify the crystalline substances produced. The boundary curves of the various phases have been determined and the quintuple points fixed. It is shown that the following crystalline substances are stable in contact with the liquid phase: periclase (MgO), corundum (Al_2O_3), tridymite (SiO_2), forsterite ($2\text{MgO} \cdot \text{SiO}_2$), clinoenstatite ($\text{MgO} \cdot \text{SiO}_2$), spinel ($\text{MgO} \cdot \text{Al}_2\text{O}_3$), sillimanite ($\text{Al}_2\text{O}_3 \cdot \text{SiO}_2$), and a ternary silicate, $2\text{MgO} \cdot 2\text{Al}_2\text{O}_3 \cdot 5\text{SiO}_2$, which may be regarded as an end member in the cordierite series. This last compound is unstable at its melting point, and is considerably affected by solid solution. It has been observed in two forms: the μ -form (unstable) crystallises from glass at temperatures below 950°C . and is transformed at a somewhat higher temperature into the stable α -form. The properties of both forms, but more especially those of the α -form, are very like those of the mineral cordierite. Seven quintuple points have been established which lie respectively at 1345° , 1425° , 1460° , 1370° , 1360° , 1375° , and 1700°C . (Compare *J. Chem. Soc.*, 1918, ii., 199.)—J. F. S.

Lead; The sub-bromide and sub-chloride of — H. G. Deham. *Chem. Soc. Trans.*, 1918, 113, 249–256.

LEAD sub-chloride and lead sub-bromide have been prepared by a similar process to that employed in the case of the sub-iodide (this J., 1917, 336) by passing ethyl chloride or ethyl bromide vapour over lead sub-oxide at 311° and 261°C . respectively. Both compounds are grey, sparingly soluble, fairly stable in air, and readily oxidised by bromine water. The sub-chloride has a solubility of 2.2 milliequivalents per litre and the sub-bromide 0.4 milliequivalent per litre. The sub-salts are readily decomposed by acids into the normal salt and metal. In the preparation of the sub-chloride the reaction is very slow, and it is not necessary to carry it out in the presence of silica.—J. F. B.

Holmium and dysprosium. Rare earths. V. H. C. Kremers and C. W. Balke. *J. Amer. Chem. Soc.*, 1918, 40, 592–598.

THE fractionation of the bromates of yttrium earths effects a rapid and efficient concentration of dysprosium and holmium. Starting with 12 kilos. of rare earth oxalates from gadolinite which were converted into bromates, three parallel series of 50 recrystallisations were carried out. The series showed a concentration of samarium, neodymium, and praseodymium towards the insoluble end, dysprosium and holmium in the central portion, and yttrium, thulium, and erbium towards the soluble end. At this point the dysprosium-holmium material was removed from the three series, combined, and made into three new series, A, B, and C. Series A consisted of the more soluble fractions, and contained dysprosium, holmium, erbium, and

yttrium. Series B contained the fractions richest in holmium and dysprosium, with small quantities of neodymium, praseodymium, erbium, and yttrium. Series C was composed of the less soluble bromates, and contained holmium, dysprosium, terbium, neodymium, praseodymium, and traces of erbium and yttrium. The three series were fractionated in parallel. The concentration of the earths in the different series was controlled mainly by the colour of the solutions. As the holmium and dysprosium became concentrated towards the less soluble end of series A these fractions were added to series B, placing them where the fractions showed a similar colour. From series C the more soluble dysprosium and holmium fractions were removed and added to series B in the same way. In the same manner yttrium and erbium, which collected in the soluble end of series B, were added to series A, and the neodymium and praseodymium from the less soluble end of B were placed in C. The three series were recrystallised 30 times, which caused most of the dysprosium and holmium to collect in series B. This series was eventually given a further 60 recrystallisations, which caused the holmium and dysprosium to concentrate very rapidly. A difficulty was experienced due to the repeated separation of basic cerium bromate as a brown sludge. It is therefore recommended that cerium be removed by the sodium sulphate method before the fractionation commences. Fusion of a mixture of the nitrates of samarium, yttrium, and holmium gave a rapid concentration of the holmium. A mixture which had an equivalent of 98.6 at the start gave after 31 fusions four end fractions with equivalents 154.3–155.2. Attempts to separate holmium and yttrium by this method failed, and it was only after the addition of samarium that the separation became possible.—J. F. S.

Dysprosium; Purification and atomic weight of — *Rare earths.* VI. H. C. Kremers, B. S. Hopkins, and E. W. Engle. *J. Amer. Chem. Soc.*, 1918, 40, 598–611.

Dysprosium material of a high state of purity has been further fractionated as ethyl sulphates and as bromates. Fractionation of the ethyl sulphates is more efficient than that of the bromates for the separation of dysprosium from neodymium, praseodymium, and terbium, but neither of the methods is efficient for the separation of holmium and dysprosium. For the atomic weight of dysprosium, determined from the ratio $\text{DyCl}_3 : 3\text{Ag}$, the value 162.52 was obtained. (See also *J. Chem. Soc.*, 1918, ii., 202.)—J. F. S.

Diamond; Formation of — C. A. Parsons. *Inst. Metals*, May 2, 1918.

UP to the present diamonds have only been produced by the more or less rapid cooling of intensely heated silver (black diamonds, Mansard, 1880–1881) or iron (transparent diamonds, Moissan). The author's experiments were designed to test Moissan's theory that pressure is the determining factor in causing the crystallisation of carbon. Experiments under varied conditions to obtain diamond from carbon or carbon compounds by the combined action of very high temperatures and pressures (see this J., 1918, 174 R) proved unsuccessful, and it is concluded that pressure alone will not account for the production of diamond through the cooling of an ingot of carbon-containing iron. The effective agent is occluded carbon monoxide, the escape of which is prevented by the solidification of the outer layers of the ingot. Experiments show that if the ingot is heated in a vacuum and freed from gas, no diamond is produced. In a low vacuum of 1 in. of mercury, the gas present being carbon monoxide, diamonds up to 0.7 mm. in length were formed. It is significant that the greatest quantity of diamond

found in an iron ingot is estimated to be $\frac{1}{26000}$ th the weight of the iron and $\frac{1}{1000}$ th part of the carbon present, this amount of carbon being almost exactly equal to that estimated to be originally present in the iron as carbon monoxide. The diamond is probably formed not far from the recalcrescence point at 690° C., for it is known that diamond is rapidly corroded by carburised iron just before setting. Little can yet be said about the actual mechanism of diamond formation. There is strong evidence to support the view that the action may take place solely between iron, carborundum, sulphur, and carbon monoxide, but it is quite possible that other metals or their carbonyls may be involved. The possible mode of formation of diamond in nature is discussed, and the suggestion of Bonney, that eclogite is the parent rock of South African diamonds, is found to be in agreement with the author's conclusions.—E. H. R.

Iodine; Recovery of — from dilute residues.

H. F. Stevenson. Analyst, 1918, 43, 165–166.

The neutral or faintly acid liquid (e.g., waste liquids from Nessler and oxygen absorption tests) is treated with mercuric chloride to precipitate the iodine as mercuric iodide. The latter is treated, in a moist condition at about 45° C., with a mixture of nitric acid, 1, and hydrochloric acid, 5 vols., added in small quantities at a time. The reaction is complete when all the red mercuric iodide has disappeared. The mixture is then cooled, the iodine collected on a filter, and washed until free from mercury; mercuric chloride may be recovered from the filtrate. To convert the iodine into iodide, iron filings, 1, and water, 10 parts, are placed in a large flask and the moist iodine, 4 parts, is added gradually with shaking; the mixture is heated subsequently, treated with a slight excess of potassium hydroxide, the ferric hydroxide is separated, and the potassium iodide crystallised from the solution.—W. P. S.

PATENTS.

Sulphurous anhydride; Manufacture of —. M. Kaltenbach, Paris. Eng. Pat. 107,589, June 26, 1917. (Appl. No. 9171 of 1917.) Under Int. Conv., May 23, 1916.

Gases derived from the combustion of sulphur are passed through a column into which an alcohol, preferably ethyl alcohol, is sprayed, to absorb the sulphur dioxide, which is subsequently recovered by heating the solution and condensing the liberated gas. The alcohol for absorbing the gas is cooled previously by a portion of the liquefied gas. The solution which has been heated to expel the gas is used to heat a further quantity of solution, and the liberated gas is partly cooled by some of the cold solution prior to heating the latter to extract sulphur dioxide.—W. F. F.

Sulphur dioxide or the like from gases containing the same; Recovering —. Apparatus for segregating and recovering gases. U. Wedge, Ardmore, Pa., and F. A. Eustis, Milton, Mass. U.S. Pats. (A) 1,260,492 and (B) 1,260,493, March 26, 1918. Dates of appl., May 29 and July 10, 1915.

(A) In a continuous process for recovering sulphur dioxide from furnace gases, a solution of sulphur dioxide is obtained by treating a portion of the gas with a liquid. Part of this solution is then brought into contact with a fresh portion of the hot gas, or is heated by the same while spread over a large area under reduced pressure. This portion of gas, now cooled and enriched in sulphur dioxide, is treated with the remainder of the solution, and the sulphur dioxide is finally recovered from the latter by known means. (B) The apparatus consists essentially of a primary and a secondary

absorption tower, and a vacuum pan. Means are provided for conveying to the primary, a portion of the liquid discharged from the secondary tower, and for conveying another portion of the same liquid to the vacuum pan. The latter has a packing of porous material through which the liquid is caused to pass before entering the discharge conduit; and the outlet from the vacuum pump communicates with a compression pump.—W. E. F. F.

Titanic acid; Production of —. Det. Norske Aktieselskab for Elektrokemisk Industri, Norsk Industri-Hypotekbank, Christiania, Norway. Eng. Pat. 108,850, May 18, 1917. (Appl. No. 7213 of 1917.) Under Int. Conv., Aug. 9, 1916.

To produce titanic acid practically free from iron, a solution of quadrivalent titanium (and other metals, including iron) is boiled with a compound of trivalent titanium, the latter being added as such or formed by reduction within the original solution. For example, a solution of titanium and iron sulphates, obtained by treating ilmenite with sulphuric acid, is electrolysed with diaphragm and lead cathodes until all the ferric sulphate is converted into ferrous sulphate and about 5% of the titanium is reduced to the trivalent condition. The electrolysis is then discontinued and the liquid heated to boiling when, owing to the reducing action of the trivalent titanium, re-oxidation of the ferrous sulphate is prevented and a white precipitate of metatitanic acid produced, all the reduced titanium remaining in solution.—W. E. F. F.

Ammonium perchlorate; Manufacture of —. Aktiebolaget Carlit, Stockholm. Eng. Pat. 110,541, Sept. 24, 1917. (Appl. No. 13,721 of 1917.) Under Int. Conv., Sept. 25, 1916.

In the manufacture of ammonium perchlorate by double decomposition of ammonium sulphate and sodium perchlorate, the liquor is evaporated under reduced pressure at temperatures between 45° C. and 100° C., preferably commencing at 60° C. and rising to 80°–85° C. The sodium sulphate is thus deposited in an anhydrous state without admixture of perchlorate, and a strong solution of the latter is obtained.—W. P. F.

Sulphate of soda from chrome residues; Manufacture of —. E. P. Potter and Co., and E. P. Potter, Little Lever, Lancs. Eng. Pat. 114,501, Apr. 28, 1917. (Appl. No. 6009 of 1917.)

To recover sodium sulphate and chromium oxide from the residues obtained in the manufacture of sodium bichromate by the action of sulphuric acid on sodium chromate, the material is heated to incipient fusion with an excess of reducing agent (metallic iron, pyrites, sulphur, coal, etc.) and the mass lixiviated, the chromium being recovered as dissolved in water and the solution is treated with sulphur dioxide, hydrogen sulphide, or an organic compound. In either case chromium oxide or hydroxide is separated by filtration, and the colourless liquors are evaporated for the recovery of sodium sulphate by crystallisation. Alternatively, a mixture of the chrome residues with an excess of a lead compound, e.g. lead sulphate ("chamber bottoms"), is heated to incipient fusion and the mass lixiviated, the chromium being recovered as lead chromate by filtration, and the sodium sulphate by crystallisation.—W. E. F. F.

Caustic potash; Removal of soda from feldspars or natural or artificial silicates or aluminates and manufacture of commercially pure —. E. A. Ashcroft, London. Eng. Pat. 114,743, July 20, 1917. (Appl. No. 10,435 of 1917.)

A FELSPAR, silicate, or aluminate, is pulverised, mixed intimately with an excess (say an equal

weight) of potassium chloride, sulphate, or nitrate, and heated for 2 hours to 800°–1200° C. out of contact with air and furnace gases. The soda in the felspar is thereby replaced by potash and the resulting sodium chloride is removed by solution in water. The residue is then mixed with 1–2 parts by weight of lime or magnesia or both, and the mixture digested with water or steam at 10–20 atmospheres and 200° C. for 2–6 hours. About 90% of the potash is thus obtained as commercially pure caustic potash, and is extracted by solution in water. If digestion is effected at 90 atmospheres pressure and 300° C., the extraction of the potash is practically complete. The residue may be converted into hydraulic cement clinker by drying and burning it.—W. F. F.

Alkalis from silicate rock and other silicates; Method of obtaining —. F. A. Rody, Newark, N.J., Assignor to Metallurgical Co. of America, New York. U.S. Pat. 1,260,944, Mar. 26, 1918. Date of appl., May 18, 1915.

To obtain alkalis in soluble form from leucite, felspar, or similar silicate, the latter (100 parts) is fused to a glass-like, stringy mass which is then reduced to powder (100-mesh) and digested for about an hour with water and lime (6 parts) at a pressure of 100 lb. per sq. in.—W. E. F. F.

Caustic alkalis; Powders for generating —. J. Armstrong, London. Eng. Pat. 114,896, Apr. 20, 1917. (Appl. No. 5539 of 1917.)

ALKALI carbonate and slaked lime or baryta, both in desiccated condition, are intimately mixed in suitable proportions.—W. E. F. F.

Nitre cake; Method of utilising —. E. Hart, Easton, Pa. U.S. Pat. 1,258,895, Mar. 12, 1918. Date of appl., May 24, 1917.

AN aqueous solution of nitre cake, of sp. gr. about 1.30, is cooled to about –40° C. by blowing cooled air through it, whereby sodium sulphate crystallises out as a granular mass.—W. E. F. F.

Kelp-incinerator. H. W. Judson, Long Beach, and H. A. Lowman, Wilmington, Cal., Assignors to Sea Products Co., Long Beach, Cal. U.S. Pat. 1,259,157, Mar. 12, 1918. Date of appl., Dec. 19, 1916.

The apparatus consists of a vertical, cylindrical casing having a flat bottom and an inclined top, the latter being provided with a flue and with a covered discharging opening large enough to receive kelp from a pitchfork. A gas burner is mounted centrally within the casing at some distance above the bottom; while from the vertical sides horizontal kelp-receiving bars extend towards the centre, these being of different lengths and arranged out of alignment with each other from the level of the burner to the top of the casing. A door for removal of the ashes is provided immediately above the floor of the apparatus.—W. E. F. F.

Potassium salts [from kelp]; Process of recovering —. F. K. Cameron, Salt Lake City, Utah, Assignor to Alaska Products Co., New York. U.S. Pat. 1,259,486, Mar. 19, 1918. Date of appl., May 9, 1917.

KELP is minced and strained to separate the coarser portions and produce thorough aeration, and an acid flocculating agent is then added to produce a clear liquor and a floating coagulum; the former is evaporated to crystallisation, and the latter returned for treatment with fresh kelp.—W. E. F. F.

Cyanide; Process of making —. W. H. Wright, Indianapolis, Ind. U.S. Pat. 1,259,702, Mar. 19, 1918. Date of appl., Feb. 17, 1917.

IN a process for recovering cyanogen from illuminating gas by absorption in a mixture of ferrous and alkali hydroxides, the mixture is prepared by treating an aqueous solution of ferrous sulphate with an alkali hydroxide, filtering, and suspending the precipitate in excess of aqueous alkali hydroxide. All the operations are conducted out of contact with air.—W. E. F. F.

Borax ores; Process of treating —. H. Blumenberg, Assignor to C. T. Hinman, Los Angeles, Cal. U.S. Pats. (A) 1,259,717, (B) 1,259,718, and (C) 1,259,719, Mar. 19, 1918. Dates of appl., (A) Apr. 26, (B) and (C) Nov. 16, 1916.

(A) NATIVE calcium borate is digested with nitric acid and the mixture is filtered; or, if silicates are present, the mixture is evaporated to dryness and the residue extracted with boiling water. After separation from the calcium nitrate by crystallisation, the boric acid is heated with sodium nitrate, under reduced pressure and in presence of oxygen and aqueous vapour, to produce borax and nitric acid. (B) Calcium nitrate obtained as in (A) is heated in a closed chamber, and in presence of oxygen and aqueous vapour, to produce nitric acid and calcium oxide. (C) The native calcareous borate is heated with sodium nitrate to produce a borax glass which is subsequently digested with water for the recovery of borax and calcium nitrate.

—W. E. F. F.

Nitrogen and mixtures of nitrogen and hydrogen; Manufacture of —. E. B. Maxted and T. A. Smith, Walsall. Eng. Pat. 114,663, Apr. 12, 1917. (Appl. No. 5125 of 1917.)

Air is passed over heated iron or copper until about 5% of oxygen remains, and is then mixed with hydrogen and passed through a highly heated retort filled with porous briquettes to remove the last quantities of oxygen. The water produced in the reaction is condensed and removed. The hydrogen may be replaced by a mixture of or a gas containing nitrogen and hydrogen, in which case a mixture of nitrogen and hydrogen is finally obtained.—W. F. F.

Sulphur; Process of mining —. A. F. Lucas and G. M. S. Tait, Washington, D.C. U.S. Pats. (A) 1,259,533 and (B) 1,259,537, Mar. 19, 1918. Dates of appl., Dec. 27, 1916, and Mar. 9, 1917.

(A) The sulphur in the deposit is ignited and partly burnt in a mixture of air and carbon dioxide in such proportions that sufficient heat is generated to melt a further quantity of sulphur. The molten sulphur is forced to the surface by the gas pressure. (B) Two concentric vertical passages are provided in the deposit, and hot air diluted with combustion products is passed down through the outer passage and back through the central passage so as to heat the central passage to about 450° C. A limited combustion of the sulphur is permitted and a further quantity of sulphur is volatilised, the sulphur vapour and combustion products being withdrawn through the central passage and the sulphur then condensed and removed.—W. F. F.

Sodium and potassium bitartrates; Manufacture of mixtures of —. T. Gladysz, La Madrague de Montredon, France. Eng. Pat. 107,020, June 8, 1917. (Appl. No. 8224 of 1917.) Under Int. Conv., Mar. 12, 1915.

SEE Fr. Pat. 480,620 of 1915; this J., 1917, 137.

Sulphurous anhydride; Manufacture of —. M. Kallenbach, Paris. U.S. Pat. 1,260,681, Mar. 26, 1918. Date of appl., July 21, 1917.

SEE Eng. Pat. 107,589 of 1917; preceding.

Ammonia; Purifying —. C. Bosch, Assignor to Badische Anilin u. Soda Fabrik, Ludwigshafen, Germany. U.S. Pat. 1,261,900, Apr. 9, 1918. Date of appl., June 30, 1913.

SEE Eng. Pat. 25,259 of 1912; this J., 1913, 909.

Condensers for acids. Eng. Pat. 114,706. See I.

VIII.—GLASS; CERAMICS.

Glass; Crystals of barium disilicate in optical —. N. L. Bowen. J. Wash. Acad. Sci., 1918, 8, 265—268.

IN "barium crown" and other optical glasses rich in barium there is a tendency for colourless six-sided plates upwards of 3 mm. by 2 mm. by 0.03 mm. to form on devitrification. These plates have white outlines due to the sprouting of minute plates of the same material around the edges of the larger ones. The optical properties of these plates enable them to be identified as synthetic barium disilicate (BaSi_2O_6) with a small amount of alkali disilicate in solid solution. The crystals have a melting point of 1426°C . (See also J. Chem. Soc., 1918, ii., 198.)—A. B. S.

The ternary system: magnesia - alumina - silica. Rankin and Merwin. See VII.

PATENTS.

Silicious firebrick and method of making the same. H. A. Kennedy, Clearfield, Pa. U.S. Pat. 1,260,398, Mar. 26, 1918. Date of appl., Sep. 28, 1917.

PARTICLES of silica of substantial size and free from finely-powdered silica or sand are mixed with a binder such as fireclay and made into bricks.

—A. B. S.

Silica, plastic, gannister, common, fire and like bricks; Manufacture of briquettes. —. T. Longstaff and A. D. Gairns, Crook, Durham. Eng. Pat. 114,676, Apr. 18, 1917. (Appl. No. 5441 of 1917.)

IX.—BUILDING MATERIALS.

The ternary system: magnesia - alumina - silica. Rankin and Merwin. See VII.

PATENTS.

Impregnation of wood and the like. P. Jolnerkevitch, Petrograd. Eng. Pat. 114,886, Apr. 18, 1917. (Appl. No. 5420 of 1917.)

ABOUT 0.1—1% of a sticky substance or viscous colloid, such as resin or other soap, starch, gum arabic, or glue is dissolved in water or in a solution of common salt, zinc chloride, or other salt, and 10—20% of an oily antiseptic such as creosote or resin is added. The mixture is heated to 50° — 90°C ., and is emulsified under a pressure of 100—300

atmos. The emulsion is diluted with water or salt solution until it contains 2—10% of the antiseptic. The particles of the preservative are so finely divided that they readily and uniformly penetrate the pores of wood impregnated with the emulsion under vacuum or otherwise, and a much smaller proportion of preservative is required than with other methods. Diseased portions of wood which cannot otherwise be impregnated are efficiently treated with this emulsion.—A. B. S.

Blast-furnace slag; Making articles of —. J. B. Shaw, Alfred, N.Y., Assignor to I. H. Shaw and W. G. Tlee, Trenton, N.J. U.S. Pat. 1,259,304, Mar. 12, 1918. Date of appl., May 23, 1917.

ARTICLES of a dense structure are made by collecting the molten slag discharged from a blast furnace or cupola, allowing it to settle, and adding during the settling process an agent which will accelerate the liberation of gas from the slag. The slag is poured into moulds, a thin crust is permitted to form on the surface, and the article is removed from the mould whilst the bulk of the interior is still fluid. The solid crust is then heated to about the fusion point, whilst the article is surrounded by an envelope of heated solid material which excludes air and furnace gases, and the article is finally cooled slowly.—A. B. S.

Cement; Method of making mixtures with water-reacting — and cement product. C. M. Chapman, Douglaston, N.Y., and N. C. Johnson, Englewood, N.J. U.S. Pat. 1,259,462, Mar. 12, 1918. Date of appl., Feb. 23, 1917.

A WATER-REACTING cement is wetted and subjected to a heavy grinding action until the cement forms a somewhat viscous smooth liquid mass of highly hydrated colloid with an initial set of 1 to 4 hrs. The production of concrete in which this colloid material is used is also claimed.—A. B. S.

Cement for pickling-rats. C. E. Manby, Carnegie, Pa. U.S. Pat. 1,259,651, Mar. 19, 1918. Date of appl., Sept. 21, 1916.

AN acid-resisting mortar composed of melted sulphur and carbon is stiffened by the addition of glass in the form of fibrous wool.—A. B. S.

Kieselguhr powder; Process of bonding — and product thereof. C. S. Kinnison, Birmingham, Mich. U.S. Pat. 1,259,525, Mar. 19, 1918. Date of appl., June 27, 1917.

Blast-furnace practice; Enquiry on — in the United Kingdom. Report of Committee No. 2. Iron and Steel Inst., May, 1918. [Advance copy.] 18 pages.

THE report deals with the replies received to 14 questions circularised among British blast-furnace

owners. Questions 1—9 dealt with the influence of the mechanical and chemical conditions of the raw materials on furnace working. Except in the Cleveland district, where the ores are uniform and in lumps, ironstone of coarseness varying from lumps to fines has to be dealt with. The ores are rarely broken, and no great advantage is found thereby. Durham coke appears to be the best as regards hardness and uniformity. Limestone is rarely broken to less than 8 inches. It is generally agreed that variation of efficiency is traceable to changes in the mechanical condition of the burden, but opinions are divided as to the relative importance of chemical and mechanical conditions in their effect on regularity of working. Where the necessary storage capacity exists—as is rarely the case—and the ores are graded, this is usually found to be beneficial. The tenth question dealt with the influence on working of dimensions of the bell relative to stock line, and it was generally found that the area of bell should be about one-half that of the throat of the furnace at this point. Opinion is divided as to the merits of double bells in preventing loss of gas. Question 12 on the size and quality of firebricks used for the lining revealed a great diversity of practice in this connection, and also in the use of special devices for reducing wear at the upper part of the furnace as a result of the falling of the charge. Generally a less expensive but harder burnt brick is used in this part. Experience as to the use of spare gas for calcining ore is limited, but when tried advantage was generally claimed for it (Question 13). The cleaning of gas—wet and dry—was the subject of Question 11, but the replies will be dealt with in a separate report.

—H. J. H.

Blast-furnaces; Fuel economy in —. T. C. Hutchinson. Iron and Steel Inst., May, 1918. [Advance copy.] 15 pages.

PARTICULARS are given of the working of the blast-furnaces at the Skinningrove Ironworks since 1880. At that time the output was considerably less than the average of the furnaces in the Cleveland district. To discover the cause, experiments were made on a model furnace 1-48th full size, with all conditions, including the coarseness of the charge, reduced on the same scale. The model was cut vertically into two equal portions, each half being sheeted with glass so that the disposition of the charge could be followed. It was found that segregation of the charge occurred, coarser pieces collecting at the centre and periphery with an annular layer of fines between. On increasing the diameter of the bell equivalent to a change from 13 ft. to 15 ft. full size, the fines collected at the outside with lumps within. This would facilitate the passage of gases through the charge. On making the corresponding change on the actual furnace, the coke consumption fell from 23.94 cwt. to 22 cwt. per ton of pig iron. The fines formed an adherent carbonaceous lining to the furnace, which had a protective effect, and also contributed to fuel economy by diminishing radiation losses.—H. J. H.

Coke hardness; Importance of — [in the blast-furnace]. G. D. Cochrane. Iron and Steel Inst., May, 1918. [Advance copy.] 12 pages.

The primary importance of coke hardness in blast-furnace working is affirmed and a machine—ascribed to Greville Jones—is described which permits of the measurement of the relative hardness. It consists of a drum turned at the rate of 18 revolutions per minute and having 2 angle-bars fixed inside, diametrically opposite, to turn the coke over. About 56 lb. of coke, in lumps up to the size of a man's fist, is dried on hot plates for 24 hours. Of this 28 lb. is charged into the drum, which is rotated for 1000 revolutions at 18 per

minute. The charge is then riddled over a $\frac{1}{2}$ -in. mesh and the percentage left on the riddle noted. This is called the "hardness" of the coke. These hardness figures have been compared with the working of the furnace and the connection established. Satisfactory working can only be expected if the hardness number exceeds 74%, but no special advantage could be detected when hardness figures were above 76%. Cokes with a hardness of 70% have been found to lead to very unsatisfactory working. The soft coke is believed to react more readily with carbon dioxide in the upper part of the furnace where no useful purpose is served. Laboratory experiments on the effect of a current of carbon dioxide at 750° C. supported this view. Soft coke also becomes crushed, and as a result the working of the furnace is seriously impaired. (See also this J., 1918, 60 T.)—H. J. H.

Blast-furnace bears. J. E. Stead. Iron and Steel Inst., May, 1918. [Advance copy.] 42 pages.

THE "bears" or accretions of metal found below the hearth level of a number of blown-out blast-furnaces have been examined, and the nature and origin of the various bodies identified is discussed. Kish or graphite is prominent in all the bears examined, in considerable masses sometimes interstratified with metal. The conditions of slow cooling and absence of motion favour its separation and aggregation. Graphite in spheroidal particles is found in the mass of metal, probably having separated after solidification. Considerable bodies of mixed sulphides of manganese and iron have been found crystallised together in very varied proportions: in one case the proportion of manganese sulphide was as high as two-thirds. Slow cooling of the liquid metal is doubtless favourable to the settling out and collection of these mixtures. The red compound, titanium cyanonitride, is found in large crystals. A blue-coloured compound, titanium cyanide, $Ti(CN)_2$, has been identified in a bear at the works of Cochrane and Co., Ormesby. The compound was separated in an almost pure form, as cubical crystals harder than quartz or any steel. As a mineralogical name for this dicyanide or carbonitride of titanium, cochraneite is suggested. The discovery of iron oxides, iron silicate, and decarburised iron shows that oxidising conditions are possible even below the hearth level. The percolation of steam from the foundations is put forward as an explanation of the oxidation. The presence of such material would account for the discovery of metal closely resembling puddled iron in its malleability and ductility. The iron is frequently coarsely crystalline and columnar in structure. This columnar, dephosphorised iron, has been previously described (this J., 1914, 181). The phosphide eutectic has probably been squeezed out in the process of cooling of the partly liquid interior owing to the contraction of the solid exterior. Minute crystals of the phosphide, Fe_3P , have been discovered in the body of the columnar ferrite crystals. Independent and idiomorphic crystals of phosphide and carbide of iron have been discovered in a drusy cavity of a bear. The existence of the carbosilicide of iron and manganese (this J., 1901, 721) has been confirmed by the discovery of homogeneous idiomorphic crystals. The results of a crystallographic examination of these and the phosphide crystals, due to L. J. Spencer, are given.

—H. J. H.

Blast furnaces; Copper tuyères for —. A. K. Reese. Iron and Steel Inst., May, 1918. [Advance copy.] 6 pages.

FORGED copper tuyères for blast furnaces are recommended in preference to cast iron ones. The first cost is higher, but the advantages found fully warrant this.—F. C. TH.

Heavy steel industry in India; Technical aspects of the establishment of the —. A. McWilliam. Iron and Steel Inst., May, 1918. [Advance copy.] 20 pages.

THE recent progress of the Tata Iron and Steel Co., Bengal, is described. The blast furnaces deal with an ore containing 63% of iron, a dolomite limestone as flux, and a local coke which contains 20% ash and 0.22% of phosphorous but only 0.5% of sulphur. The pig iron produced is therefore adapted for the basic process of steel manufacture, which is carried on in six 50-ton open-hearth furnaces. The company, which is now successfully supplying many of the Indian requirements in structural and rail steels, was slow at first to establish itself, mainly owing to the defective technical skill of the German staff prior to the war. It is now making "H.E. shell" steel of satisfactory quality. The addition of manganese is made while the metal is in the furnace rather than in the ladle. The firm owns its own manganese mines, and manganese losses are not a serious item. The author advocates higher limits in official specifications for manganese—up to 1%—which he finds beneficial rather than the reverse. Indian rail steels under wearing tests on the railways are proving satisfactory side by side with those from England. The author has made trials which encourage the view that it will be possible to produce acid steels when the opportunity is more favourable.—H. J. H.

[Steel] boiler plates; A cause of failure in —. W. Rosenhain and W. Hanson. Iron and Steel Inst., May, 1918. [Advance copy.] 12 pages.

A boiler plate, 1½ in. thick, broke after bending. The steel contained C 0.16, Si 0.08, Mn 0.62, S 0.03, P 0.048, and Ni 0.10%. The tests given by the steel as received and after annealing gave the following results:—

	Elastic limit. Tons per sq. in.	Yield point. Tons per sq. in.	Max. stress. Tons per sq. in.	Elongation. % on 1.5 in.	Reduction of area. %
As received ...	14.2	18.3	26.9	31.6	59.6
Annealed at 550° C.	15.4	18.7	27.6	34.5	59.1
Annealed at 900° C.	18.3	19.2	27.9	42.2	62.5

The modulus of elasticity was in each case practically identical at 30×10^6 lb. per sq. in. The impact value of the steel as received, however, was only 0.75 kilogram-metre per sq. cm., which rose to 2.9 and 11.25 respectively after annealing at 550° C. and at 900° C. The fracture is ascribed to the low impact value of the plate as received, this being due to a coarse ferrite crystallisation in the carbonaceous bands of the plate. This crystallisation was the result of grain growth produced by slight deformation and subsequent low temperature annealing. This form of brittleness is eliminated by annealing at 900° C., and decreases as the thickness of the plate becomes less and the banded structure disappears. The brittleness produced by low temperature annealing after cold work increases as the degree of cold work decreases, as shown in the following table:—

Treatment.	Impact value. Kilogram metres per sq. cm.
Normalised at 900° C. ...	10.46
Do. and annealed at 650° C. ...	9.04
Reduced 12.4%, and annealed at 650° C.	10.66
" 6.9% " " " "	10.04
" 4.9% " " " "	8.14
" 3.0% " " " "	6.34

—F. C. TH.

[Steel;] Effect of mass on heat treatment [of —]. E. F. Law. Iron and Steel Inst., May, 1918. [Advance copy.] 15 pages.

To determine the effect of the mass of the sample of steel on heat treatment, heating and cooling experiments were made on 18-in. cubes weighing 14½ ewt. The steel used contained C 0.31, Si 0.19, Mn 0.74, S 0.022, P 0.032, and Ni 0.20%. The heating curve of this steel shows Acl at 730° C. and Ac3 at 820° C. On cooling, Ar3 occurs at 705° C. and Ar1 at 662° C. During the experiments three thermo-couples were inserted in each block, one ¼ in. deep, one half-way to the centre, i.e. 4½ in. deep, and the third at the centre. Each cube was heated to 900° C. in a furnace fired with Mond gas. The heating curves show that at 130 minutes from the time of charging, the metal at the centre and half-way to the centre was almost at the same temperature of 706° C.; but at this point the heat absorption due to Acl caused a greater lag at the centre, and the two temperatures did not again approximate until after another hour. After being in the furnace for about 4½ hours the cube attained a uniform temperature throughout. The cubes were then drawn and cooled respectively in air, in oil, in a water spray, and in water at 55° F. (13° C.). The air-cooled block cooled very slowly, and the heat evolution at Ar1 was clearly shown, especially at the centre. In the case of the oil-quenched mass the cooling was rapid, even at the centre, where the Ar1 point was very noticeable. The readings from the thermo-couples half-way to the centre, and ¼ in. deep respectively, gave not the slightest indication of any recalcence. The water-spray curves were similar to the oil-hardening ones, except in the lower ranges of temperature, where the cooling was in this case more rapid. The block quenched in water showed similar characteristics, but with a still greater rate of cooling. The essential difference between the oil and water quenching was found to lie in the greater time required in oil to cool down from about 500° C. Tensile tests were made on bars cut from the blocks. In the air-cooled block all yielded practically the same result, but in the other cases test-bars from the outer portion showed distinctly higher yield-points and maximum stresses than did test-bars from nearer the centre. The greatest difference was shown by the water-quenched block, the oil-quenched one, due to the "automatic tempering," showing the least. The properties of steels up to 250° C. are discussed in connection with an apparent transformation at 120° C.—F. C. TH.

Damascene steel. N. Belaw. Iron and Steel Inst., May, 1918. [Advance copy.] 22 pages.

DAMASCENE steel, which may contain from 1.1–1.8% carbon, is prepared in three ways: (1) by the old Indian method in a crucible from pure ore and charcoal; (2) by the Persian method from pure soft iron and graphite; (3) by a heat treatment like a very prolonged tempering. The characteristic "watering" is referred to the original austenite dendrites distorted by the forming. Very slow cooling in the furnace from fusion gives a coarse crystallisation and a "milky way" of cementite globules. The spheroidal cementite comes from the slow cooling, or in the third process from the break-up of cementite cell walls and streaks at a very dull red heat. It is to this type of occurrence of the cementite that the remarkable ductile and elastic behaviour of this steel is ascribed. It is necessary that the forging should not be carried out at a temperature above the dull red.—F. C. TH.

Steel springs; Brittleness produced in — by electroplating. O. P. Watts and C. T. Fleckenstein. Amer. Electrochem. Soc., Apr.-May, 1918. [Advance copy.] 5 pages

BRITTLENESS was produced in steel watch springs

by electrolytic pickling in various electrolytes when hydrogen was evolved on the spring which served as cathode. After removing the grease from steel springs by treating with a hot alkaline solution, it was found possible to remove the "bluing" without causing brittleness by boiling in a 10% solution of ammonium citrate. When the springs were plated in cyanide baths, brittleness ensued whenever the evolution of hydrogen was detected; but the springs were not rendered brittle in silver or gold baths from which no hydrogen was evolved. Cyanide does not promote brittleness, which is probably caused, during either pickling or plating, by hydrogen. (Compare Thompson and Richardson, this J., 1917, 219.)—C. A. K.

Steel; Determination of carbon in —. L. Dufty. Analyst, 1918, 43, 167.

The direct-combustion method (burning the drillings in oxygen) is more accurate and more rapid than the solution method (dissolving the drillings in copper-potassium chloride and burning the insoluble residue). The drillings must be thin, and the addition of an oxidising agent, such as bismuth oxide, is recommended, especially in the case of mild carbon steels. The solution method may be used for plain carbon steels, but is useless for high-speed steels and those containing molybdenum.

—W. P. S.

Ferro-silicon; Methods for the commercial analysis of —. E. M. Anger. Amer. Electrochem. Soc., Apr.—May, 1918. [Advance copy.] 8 pages.

CARBON is estimated by burning 0.5 gm. of the finely-ground sample, with addition of 2 grms. of the fine mild steel turnings of known carbon content, to facilitate combustion. The solution of the finely-ground sample for analysis is effected by covering 0.5 gm. in a platinum dish with 10 c.c. of dilute nitric acid (1:1) and slowly adding hydrofluoric acid, drop by drop, until solution is complete. The solution is evaporated to dryness, and the residue dissolved in nitric acid. Manganese, calcium, magnesium, and sulphur are determined in this solution by known methods. Total phosphorus is precipitated by ammonium nitromolybdate; the small residue left undissolved when the solution is prepared as described above must be rendered soluble by fusing with sodium carbonate, as it contains a large proportion of the phosphorus. Phosphorus which can be liberated as hydrogen phosphide is determined by treating the ferro-silicon with 40% caustic soda solution, absorbing the hydrogen phosphide in bromine, and subsequently precipitating. For the determination of iron, hydrogen peroxide is used instead of nitric acid in preparing the solution, and the hydrochloric acid solution is reduced with stannous chloride and titrated with bichromate. When titanium and barium are to be determined, a small quantity of sulphuric acid must be added in the process of solution, otherwise these elements volatilise as fluorides. For the determination of silicon, ferro-silicon with up to 25% Si can be decomposed by carbonate fusion in a platinum crucible, but with higher proportions of Si, the platinum is rapidly attacked. Fusion with sodium peroxide in iron crucibles is recommended. An approximate method, accurate to 0.5%, is based on the evolution of silicon as tetrafluoride by the solution process described above, with subsequent ignition of the residue to oxides. A factor should be used to counteract the difference in the weight of aluminium and iron —C. A. K.

Zinc or spelter; Effect of impurities on the hardness of cast —. G. C. Stone. J. Amer. Inst. Metals, 1918, 12, 11.

The hardness of a series of samples of commercial zinc of known composition was measured by the

load in lb. per sq. in. required to reduce the length of a test piece by 20%. Lead alone has practically no effect. Up to 0.1% iron has no effect, but in large quantities this metal renders spelter hard and very brittle. The hardness increases with the cadmium content, and it seems that cadmium is practically the sole cause of hardness in commercial spelter.—F. C. TH.

Brass; Volatility of the constituents of —. J. Johnston. J. Amer. Inst. Metals, 1918, 12, 15.

AFTER considering briefly the vapour pressures of some pure metals at temperatures up to 1150° C. (see this J., 1917, 1132), the relationship of the partial pressure of zinc in brasses of varying compositions to the vapour pressure of pure zinc at the same temperature is examined. This ratio is almost independent of temperature. The values of this ratio for the most important brasses are:—

Percentage of zinc	...	40	35	30	20
Ratio	...	0.27	0.21	0.15	0.05

The results indicate that, of the total zinc present in ordinary brasses, only a portion is present in solution as zinc itself, the remainder existing as a compound with copper. In the 70:30 brass half the zinc is free and half combined; in a 60:40 brass two-thirds is free. It is suggested that the compound is CuZn. Comparison of the partial pressures of the zinc in different brasses at their casting temperatures indicates that there is more danger of loss of zinc in pouring the high-zinc alloys than in those of lower zinc content, despite the higher temperature required in the latter case. With regard to the other constituents which may be present, the loss by volatilisation of copper and iron is negligible. In the case of lead the loss will be greater if it occurs free than if it is in solution. The loss of cadmium in practice is about four times that suggested by the volatilisation figures obtained, the discrepancy probably arising from the action of this metal as a deoxidiser.—F. C. TH.

Bronze and brass; Non-metallic inclusions in —. G. F. Comstock. J. Amer. Inst. Metals, 1918, 12, 5.

SPECIMENS were prepared by adding the element of which the oxide was desired to molten over-oxidised copper. Cuprous oxide, which is soluble in molten copper, occurs in the solid metal as an eutectic containing 3.5% Cu₂O or 0.29% O. The other elements added all reduced the cuprous oxide. Tin oxide occurs in angular crystals or needles of very dark bluish-grey colour; it always appears to be pitted, especially after etching, and stands out in relief with dark black edges. It apparently does not occur in the form of cell walls. Zinc oxide in brass is distinguishable from tin oxide by its lighter colour, smoother surface, rounded form, and the absence of very dark outlines. This oxide may occur as films around the crystals. The oxides of manganese and phosphorus yield no typical inclusions. The phosphide present in phosphor-bronze may be distinguished from the $\alpha\delta$ eutectoid by etching with 50% nitric acid, which attacks the eutectoid but leaves the phosphide perfectly bright. Etching with ferric chloride and ammoniacal hydrogen peroxide does not differentiate between these constituents, but in the unetched condition the phosphide is rather darker, and, being harder, stands out in relief. The sulphide present in phosphor-bronze has a bluish colour when unetched. No reagent has been found to attack it, whence it stands out clearly from the dark background of the etched alloy. This fact enables it to be distinguished from zinc oxide, which in colour and form it otherwise resembles. Alumina presents exactly the same appearance in bronze as in steel, i.e., small

black specks closely grouped without coalescing. Irregular in shape, and with rough edges. Silicates occur in form similar to slag in steel. Sand occurs in smooth angular fragments, dark grey in colour, and with convex sides. Inclusions with concave sides consist of slag.—F. C. Tu.

Tungsten [in ores]: Rapid determination of —.

F. W. Foote and R. S. Ransom, jun. Eng. and Min. J., 1918, 105, 835.

ONE GRM. of finely powdered ore is mixed with 1.2 grm. of a mixture of calcium carbonate and sodium chloride (1:1) in a porcelain crucible and heated gently at first, then with the full heat of a Bunsen burner. The cold mass is transferred to a dish and digested on a water-bath with 40 c.c. of strong hydrochloric acid; 15 c.c. of nitric acid is added and the liquid concentrated to 15 c.c. after 15 minutes' digestion. It is diluted with 100–125 c.c. of boiling water, allowed to stand 2–3 hours, filtered, and the precipitate washed three times with 2% hydrochloric, and twice with 2% nitric acid. The residue of tungstic acid and silica is treated as usual.—W. R. S.

Molybdenum ores and concentrates; Assay of —.

H. C. Mabce. Eng. and Min. J., 1918, 105, 836–837.

FROM 0.5 to 1 grm. of the sample is treated with 2–3 c.c. of fuming nitric acid in a silica or platinum crucible of 50-c.c. capacity, and the mixture evaporated just to dryness. The residue is fused with 30 grms. of potassium bisulphate, the product leached with hot water and heated till completely dissolved, and the iron precipitated with ammonia. The washed precipitate should be dissolved and reprecipitated. Fifty c.c. of sulphuric acid (1:1) is added to the filtrate, which is passed through a 24-in. reductor into a 1-litre flask, using suction. The reductor contains 10-mesh zinc previously washed with hot sulphuric acid (1:1); 20 c.c. of 15% ferric alum solution and 20 c.c. of "titrating mixture" are placed in the receiver. After the molybdenum solution has been drawn through the reductor, the latter is washed at least four times with hot sulphuric acid (1:1); the solution is filtrated warm with permanganate standardised against pure molybdenum trioxide, following the same procedure as in the actual determination.

—W. R. S.

Chromium; Passivity of —. A. H. W. Aten. Proc.

K. Akad. Wetensch. Amsterdam, 1918, 20, 812–823.

THE existence of chromium in active and passive forms is probably the cause of the divergent results which have been obtained in previous attempts to determine the electrode potential of chromium. New experiments made with electrolytic chromium and with chromium prepared by Goldschmidt's "thermit" process have given -0.47 volt for the potential of active chromium in contact with chromous sulphate solution with reference to the hydrogen electrode as standard. The attainment of this value requires the presence of hydrogen which acts as catalyst and produces the true contact equilibrium. (See also J. Chem. Soc., June, 1918.)—H. M. D.

Electrolytic behaviour of manganese in sulphate solutions. Van Arsdale and Maler. See XI.

PATENTS.

High speed or special steels; Manufacture of tools from scrap of —. Soc. Ind. des Métaux de Synthèse, Paris. Eng. Pat. 112,412, May 1, 1917. (Appl. No. 6156 of 1917.) Under Int. Conv., Dec. 30, 1916.

HIGH-SPEED steel scrap is heated in closed crucibles to about 1200° C., and potassium ferrocyanide added, preferably less than 5% of the mass treated. The temperature is then raised to 1800° C., and the metal cast, with or without a further small addition of ferrocyanide. It is claimed that the metal is free from blow holes. A small amount of barium or other suitable chloride may be added to aid the formation of slag.—C. A. K.

Case-hardening of iron and steel articles; Carburisation and —. W. Fennell, and The British Carbonizing Co., Ltd., Gloucester. Eng. Pat. 114,446, Jan. 27, 1917. (Appl. No. 1388 of 1917.)

THE articles embedded in carburising material are heated in a closed rotating chamber or muffle in presence of a gas (e.g., coal gas or carbon monoxide) under pressure (e.g., 15 lb. per sq. in.). The gas may be evolved from the charge of carburising material.—W. R. S.

Case-hardening iron and steel; Process of —. J. R. Messersmith, Cincinnati, Ohio. U.S. Pat. 1,260,787, Mar. 26, 1918. Date of appl., July 19, 1916.

THE case-hardening mixture is composed of potassium ferrocyanide, 1 part by vol., sodium chloride 1 part, and rosin, $\frac{1}{2}$ part by vol.—C. A. K.

Steel ingots; Casting of —. A. Reynolds, Hove, Sussex. Eng. Pat. 114,466, Apr. 2, 1917. (Appl. No. 4746 of 1917.)

IN casting steel ingots, a reservoir for the molten metal, comparable in capacity with the mould, is interposed between the casting ladle and the mould. The reservoir is constructed with a depending spout of such length that the diminution of head under which the metal flows in casting is as small as is compatible with the conditions of casting. In casting a group of ingots, a reservoir is arranged above each mould, with its nozzle co-axial with the mould. In casting a large ingot, when the metal in the mould is at a level above the chill portion, the reservoir is raised, the spout throttled, e.g. by inserting a nozzle of smaller bore, and the casting completed at a slower speed. An inverted dish may be fixed at the lower end of the spout to prevent access of air to the contents of the mould.

[Iron] mill scale, and the like; Melting and de-oxidising of —. A. Rollason, Long Eaton, Derby. Eng. Pat. 114,561, Aug. 7, 1917. (Appl. No. 11,307 of 1917.)

MILL scale or like material mixed with a suitable quantity of powdered carbon is added to 5–25% of its weight of molten pig-iron or steel scrap, and the mixture covered with a thick layer of non-oxidising material such as silicious slag. The temperature is then raised to melt the charge, the metal being de-carburised and converted into steel as usual.

—W. R. S.

Iron; Process of smelting and purifying —. G. R. Gehrant, Oak Park, Ill. U.S. Pat. 1,260,660, Mar. 26, 1918. Date of appl., Sept. 24, 1914.

THE ore is smelted and the smelted iron collected in the hearth of the furnace. Jets of air at sufficient pressure to penetrate the molten mass are

directed obliquely on to the surface of the iron. At the same time air at a lower pressure is blown into the furnace at a higher level.—C. A. K.

Iron and steel; Treatment of — to prevent corrosion. W. H. Allen, Detroit, Mich. U.S. Pat. 1,260,740, Mar. 26, 1918. Date of appl., Aug. 2, 1917.

ARTICLES of iron or steel the surfaces of which have been partly converted into iron phosphates, are immersed in an aqueous solution of a double cyanide of iron and potassium or other alkali metal.

—C. A. K.

Iron, titanium, and silicon; Alloy of — and process for the production thereof. N. G. Petinot, New York, Assignor to United States Alloys Corporation. U.S. Pat. 1,260,037, Mar. 19, 1918. Date of appl., Mar. 7, 1917.

AN alloy containing Fe 69–80%, together with titanium and silicon, in which the ratio of titanium to silicon is not less than 80:20 nor more than 85:15, is made in an electric furnace from a mixture containing excess of iron, and titanium and silicon in the above ratio, together with sufficient carbon to effect reduction; the silico-titanate slag is reduced by the iron of the bath.—W. R. S.

Metals; Process for reducing — to a finely divided state. Metals Disintegrating Co., New York, Assignees of E. J. Hall, Passaic, N.J., U.S.A. Eng. Pat. 109,258, Aug. 10, 1917. (Appl. No. 11,523 of 1917.) Under Int. Conv., Aug. 26, 1916.

METALS are ground whilst completely coated with or immersed in oil, in order to prevent oxidation or combustion of the metal. A modification includes the pulverisation of metals, under oil, in a ball mill, the oil being fed in and drawn off, intermittently or continuously, to prevent overheating, and to carry out with it material sufficiently ground.

—C. A. K.

Spelter; Process for producing — and material employed for carrying the same into effect. D. B. Jones, Chicago, Ill., Assignee of C. H. Fulton, St. Louis, Mo., U.S.A. Eng. Pat. 112,923, Aug. 10, 1917. (Appl. No. 11,498 of 1917.) Under Int. Conv., Jan. 22, 1917.

SEE U.S. Pat. 1,249,061 of 1917; this J., 1918, 95 A. Before distilling the zinc, the briquettes are preheated to expel volatile matter from the carbonaceous binding material. One or more of the briquettes may be interposed as a continuous resistor between the electrodes of an electric furnace, and a current passed in order to heat the material to a temperature sufficient to distil the zinc.

Zinc-bearing material containing iron; Treatment of —. A. G. Betts, Asheville, N.C. U.S. Pat. 1,239,594, Mar. 19, 1918. Date of appl., Apr. 21, 1916.

OXIDISED zinc ore containing iron is treated with an acid solution in such a manner as to leach out the greater portion of the zinc with a minimum of iron; the residue is again leached with an acid in presence of sulphur dioxide, the liquor treated with metallic iron, and electrolysed.—W. R. S.

Gold alloys and the preparation thereof. K. Shiga, Takachiho-mura, Japan. Eng. Pat. 114,447, Feb. 26, 1917. (Appl. No. 2814 of 1917.)

THE alloys contain gold (more than 80%) and nickel, or gold (more than 65), nickel (less than 20), and tungsten (less than 15%). The gold-nickel alloy is made by melting alternate layers of the metals in the form of thin sheets in a crucible. For the manufacture of the ternary alloy, a nickel-

tungsten alloy is produced first, and thin sheets of this are melted together with gold. Small quantities of cobalt, chromium, manganese, or silver may also be added. The alloys can be beaten into very thin leaves or drawn into fine wires. They are not attacked by acids (except *aqua regia*) or alkalis, and are not affected by high temperatures.—W. R. S.

Furnaces for heating ingots. G. J. Davies, Loughor, Glam. Eng. Pat. 114,570, Aug. 27, 1917. (Appl. No. 12,253 of 1917.)

THE "skid" or track along which ingots travel inside a heating furnace has a knee or bend at one end where the heat is greatest, and has imbedded within it a continuous pipe for the flow and return of cooling water.—T. H. B.

Furnaces; Crucible and like —. J. Gaunt, D. Brookfield, and J. Tylor and Sons, Ltd., London. Eng. Pat. 114,684, April 30, 1917. (Appl. No. 6093 of 1917.)

IN a crucible furnace the air blast is preheated by passing it through an annular chamber between the refractory wall and the casing of the furnace. This chamber is provided with baffles so as to give a circuitous up and down path to the air before it reaches the grate. A hinged tray of suitable construction is provided for the easy removal of the ashes.—C. A. K.

Furnaces; Electric induction — [for melting and refining metals]. C. B. Foley, Ann Arbor, Mich., U.S.A. Eng. Pat. 114,853, Apr. 13, 1916. (Appl. No. 5442 of 1916.)

THE furnace is formed of a crucible, having in its lower part a circular hollow cross-member, the position of which is such, relatively to the bottom of the crucible, that a narrow passage is left between the lower part of the tubular member and the bottom of the crucible. The axis or axes of curvature of the inner walls of the crucible are different from that of the refractory cross-member, and the walls of the crucible slope outwards in an upward direction, so that the passage gradually widens on each side of the cross-member; the top of the crucible may be contracted inwards. A primary electrical winding, carried by a closed magnetic core, is arranged within the hollow member, which is completely surrounded by the molten secondary, and the plane of the core is so fixed that it includes the narrow passage corresponding to the smallest cross-section of the molten secondary. Several such cross-members may be provided to form channels, whereby the conditions of polarity and the temperature within the body of the secondary may be varied, the space between the different cross-members being greater than that between the members and the walls of the receptacle. The means for controlling the relative polarities of the electromagnet are adapted to produce zones of different temperatures on opposite sides of the inducing means, the hottest zone being at the bottom of the crucible, a relatively cooler zone between the cross-members and the walls, and the coolest zone between the inducing means. The induced or secondary current is made to circulate in series relation about the current inducing means, or about each inducing means by itself. The crucible is adapted to contain a high head of molten material, and the cross-section of the crucible area occupied by the secondary circuit is so proportioned that at any depth of secondary, measured vertically from the surface, except the greatest depth at the bottom of the crucible, the "pinch effect" forces tending to rupture the secondary will be substantially less

than the hydrostatic pressure at that depth. At the bottom of the crucible, the "pinch effect" forces are equal to the hydrostatic pressure when the apparatus is carrying its maximum input of current. The current density is therefore such as to obtain the most efficient circulation due to the so-called "pinch effect," and at the same time prevent the rupture of the molten material forming the induced secondary circuit.—B. N.

Furnaces for roasting ores. F. W. Harbord, Westminster, Eng. Pat. 114,953, Aug. 9, 1917. (Appl. No. 11,464 of 1917.)

Is a roaster of the tunnel type the hearth is divided into sections, each of which can be moved through the furnace supported on trolleys which travel on rails or water-cooled guides. The furnace may be horizontal, or slightly inclined to facilitate the movement of the hearths. The furnace itself is divided into two portions, one of which is muffled and heated externally. When once the furnace is heated up, the necessary heat is supplied to the other portion of the hearth by the combustion of sulphur in the ore. Both parts of the furnace form one continuous chamber and the sulphur gases produced are drawn through this chamber to the sulphuric acid plant, being unmixed with the products of combustion. During its passage through the furnace the ore is rabbled by the motion of the hearths past rakes fixed in the crown of the furnace and extending nearly to the hearth, preferably in the form of firebrick blocks or teeth set at suitable intervals. Air for the combustion of the sulphur may travel in the same direction as the hearths or in the opposite direction. The furnace is particularly suitable for sulphide ores such as blende, galena, or pyrites.—C. A. K.

Roasting pyrites, ores, or the like in shelf-burners. A. G. Bloxam, London. From Zellstoff-fabrik Waldhof, Mannheim-Waldhof, Germany. Eng. Pat. 114,954, Aug. 10, 1917. (Appl. No. 11,535 of 1917.)

The chief disadvantage of the shelf burner is that while a certain number of shelves are required for the complete roasting of one material, if a change is made to another grade of material the roasting may be complete at the middle shelf. This is overcome by fixing a second hopper to feed raw material to a lower shelf on which it mixes with partly burnt material arriving from the upper shelves.

—C. A. K.

Melting furnace. A. Fisher, Chicago, Ill. U.S. Pat. 1,258,666, Mar. 12, 1918. Date of appl., Dec. 4, 1916.

The furnace is in the form of a drum mounted to rotate on a horizontal axis. It is closed at one end by a removable door, and tapers from this end towards the opposite burner end, the portion adjacent the burner being cylindrical and forming a combustion chamber from which the heat is conducted by the lining of the drum underneath the metal resting on the sloping bottom. The lining of heat-resisting and heat-conducting material is in the form of parallel ring-shaped sections. The removable door carries a trunnion to form the axis of rotation, and from that end the rings forming the lining may be easily removed by tilting the furnace to a vertical position.—T. H. B.

Annealing furnace. I. W. Foltz, Chicago, Ill. U.S. Pat. 1,258,885, Mar. 12, 1918. Date of appl., Mar. 23, 1916.

The furnace comprises a fire-box and a combustion and annealing chamber, with air inlet conduits along the sides of the combustion chamber and

exposed to the combustion gases therein. These conduits communicate with the space formed between the side walls of the fire-box and false walls spaced apart from the side walls. Air-supply conduits are arranged at the opposite side of the combustion chamber with transverse distributing conduits at intervals along the top of the chamber communicating with the supply conduits. The roof of the fire-box has an air conduit with an outlet in the fire-box, and a baffle wall with a vertical passage therein depends from the roof, the passage communicating at its upper end with the fire-box, and at its lower end with the combustion chamber.—T. H. B.

Electro-deposition of base metals (copper, zinc); Process for the —. A. A. Lockwood, Merton Park, Surrey, Eng. Pat. 114,976, Oct. 3, 1917. (Appl. No. 14,286 of 1917.)

The base metals are deposited electrolytically from solutions derived from the treatment of ores and the like, in a vacuum or under reduced atmospheric pressure varying in degree, mainly according to the complexity and density of the electrolyte. By this means the need for clarification of the solution is generally obviated, polarisation is prevented, evanescent insulation (due to gas bubbles) is avoided, and the metal is deposited more rapidly and in a denser form.—B. N.

Lead chloride and chlorine gas; Process of treating ores to produce —. J. L. Malm, Denver, Colo. U.S. Pat. 1,258,800, Mar. 12, 1918. Date of appl., Dec. 12, 1914.

An ore containing lead and other sulphides is treated with chlorine gas in the presence of moisture at a temperature sufficient to convert the lead into sulphate, with hydrochloric acid as a by-product. The lead sulphate is converted into chloride and extracted by means of hot concentrated brine, and the solution cooled to precipitate lead chloride, from which lead and chlorine are recovered, the latter being used again in the initial stage of the process.—T. H. B.

Concentrating ores; Process of and apparatus for —. J. M. Callow, Salt Lake City, Utah, Assignor to Metals Recovery Co., Augusta, Me. U.S. Pat. 1,258,869, Mar. 12, 1918. Date of appl., Feb. 4, 1915. Renewed, Aug. 1, 1917.

The ore pulp is fed into a vessel provided with an overflow at its upper end, a tailings-separating chamber with an outlet in its lower portion, and a pipe through which a current of gas is passed upwards through the pulp, by which the coarse particles are separated from the fine; the latter overflow into a flotation cell, where they are subjected to flotation.—W. R. S.

Copper alloys containing strontium; Composition of —. F. C. Frary, Niagara Falls, N.Y., and S. N. Temple, St. Paul, Minn. U.S. Pat. 1,258,886, Mar. 12, 1918. Date of appl., Mar. 31, 1916.

An alloy, harder than copper, consists mainly of that metal, with a small amount of strontium.—T. H. B.

Copper [sulphide] and like ores; Smelting —. T. W. Cavers, Copperhill, Tenn. U.S. Pat. 1,259,467, Mar. 12, 1918. Date of appl., June 29, 1917.

A blast of air carrying a relatively small amount of carbonaceous fuel, and material containing matte-forming metal, is blown into the lower part of the blast-furnace at a point somewhat above the slag level.—T. H. B.

Metals [lead, zinc, iron, and arsenic]; Process of extracting — from ores, &c. C. C. Nitchie, Depue, Ill., Assignor to New Jersey Zinc Co., New York. U.S. Pat. 1,258,934, Mar. 12, 1918. Date of appl., Nov. 19, 1915.

ORES, fumes, or other metalliferous materials are heated with ammonium sulphate at such a temperature that zinc and iron are converted into sulphates and ammonia is driven off, with some of the arsenic, then heated to higher temperature (e.g., 600°–650° C.) to decompose iron sulphate and expel more arsenic without decomposing the zinc sulphate, the latter being afterwards dissolved out, leaving a residue containing lead, and practically free from zinc.—T. H. B.

[Vanadium.] *Method of recovering values from by-products and ores.* J. J. Boericke, Merion, Pa. U.S. Pat. 1,259,595, Mar. 19, 1918. Date of appl., July 20, 1914. Renewed Aug. 7, 1917.

VANADIFEROUS fume is condensed, roasted with an alkali, the melt leached, and the solution neutralised and precipitated with calcium hypochlorite.—W. R. S.

Magnetic separator. J. G. Sekinger, Ford City, Pa., Assignor to the Pittsburgh Plate Glass Co., Pittsburgh, Pa. U.S. Pat. 1,259,788, Mar. 19, 1918. Date of appl., July 21, 1915.

AN inclined discharge spout, open on its upper side, has a casing of magnetic material mounted on its end, the casing being provided with an opening in alignment with but of smaller cross-section than the outlet of the spout. The sides of the casing are substantially parallel to the axis of the spout. Surrounding the opening in the casing is an annular groove opening downwards, and dividing the casing into two annular pole pieces, and in the groove is a "winding." The lower face of the casing is at right angles to the axis of the winding and adapted to receive and support magnetic material which passes through the opening.—W. R. S.

Tin-scrap and the like material; Art of detinning —. O. K. Zwingenberger, Tompkinsville, N.Y. U.S. Pat. 1,260,119, Mar. 19, 1918. Date of appl., June 8, 1911. Renewed Aug. 15, 1917.

TIN scrap is treated with chlorine in the presence of moisture, whilst being protected from the influence of the moisture by means of excess of another gas, e.g., sulphur dioxide, capable of reacting with the water and chlorine to form hydrochloric acid and another product.—T. H. B.

Scrap material; Process of recovering metal from —. J. W. Brown, Lakewood, Ohio. U.S. Pat. 1,260,312, Mar. 25, 1918. Date of appl., July 15, 1914.

SCRAP material which on heating forms distinct globules or masses of molten metal is subjected to pressure at a temperature above its melting point, thus squeezing out the molten metal from the dross. The dross may be mixed with a flux and heated and stirred.—C. A. K.

Alloys; Method of recovering metals from —. J. H. Gillis, Assignor to British America Nickel Corporation, Ltd., Toronto, Canada. U.S. Pat. 1,260,661, Mar. 25, 1918. Date of appl., Sept. 4, 1917.

AN electric current is passed from an alloy (e.g., nickel-copper) electrode to a suitable cathode through an electrolyte containing a salt of the metal (nickel) to be deposited, the polarity of the electrodes being reversed at such intervals and for

such periods as to avoid deposition on the cathode of any undesired components (e.g., the copper) of the alloy anode.—C. A. K.

Tungsten ingots; Apparatus for welding —. C. A. Pfanstiehl, Waukegan, Ill., Assignor to Pfanstiehl Co., Inc., North Chicago, Ill. U.S. Pat. 1,260,949, Mar. 25, 1918. Date of appl., July 12, 1915.

IN an electric furnace for sintering or welding tungsten ingots, the latter are supported between a pair of tungsten electrodes having squared and parallel end faces, to which powdered carbon may be applied. The electrodes, which are water-cooled, are of the same cross-section as the ingot, and are held firmly against the squared ends of the latter by springs or other resilient means.—C. A. K.

Sheet lead and the like; Making —. Extruding lead and the like. J. Stratton, Bowdon, and E. A. Claremont, High Legh, Cheshire, Eng. Pats. 114,902 and 114,903, Apr. 25, 1917. (Appl. Nos. 5838 and 5839 of 1917.)

Sulphide ores; Separation of metallic —. J. Hebbard and R. J. Harvey, Broken Hill, N.S.W., Assignors to Minerals Separation North American Corporation. U.S. Pat. 1,260,668, Mar. 25, 1918. Date of appl., Aug. 26, 1914.

SEE Eng. Pat. 19,373 of 1914; this J., 1915, 1017.

Sulphide ores; Separation of mixed —. J. Hebbard, Broken Hill, N.S.W., Assignor to Minerals Separation North American Corporation. U.S. Pat. 1,261,810, Apr. 9, 1918. Date of appl., Apr. 12, 1915.

SEE Eng. Pat. 5650 of 1915; this J., 1916, 639.

Copper; Electrolytic deposition of — from acid solutions. F. E. Studt, London. U.S. Pat. 1,260,803, Mar. 26, 1918. Date of appl., July 18, 1916.

SEE Eng. Pat. 108,688 of 1916; this J., 1917, 1100.

Copper and other metals; Apparatus for electrolytic production of —. M. Perreux-Lloyd, Boulogne-sur-Seine, Assignor to M. V. Bailly, Paris. U.S. Pat. 1,262,248, Apr. 9, 1918. Date of appl., Apr. 14, 1917.

SEE Eng. Pat. 110,474 of 1917; this J., 1917, 1249.

Furnace for calcining copper and like ores. J. G. Squire, Newcastle-upon-Tyne. U.S. Pat. 1,262,126, Apr. 9, 1918. Date of appl., Feb. 14, 1917.

SEE Eng. Pat., 101,998 of 1916; this J., 1916, 1264.

Zinciferous ores; Treatment of —. J. H. and P. McP. Gillies, East Camberwell, Victoria, Australia. U.S. Pat. 1,262,190, Apr. 9, 1918. Date of appl., Jan. 22, 1917.

SEE Eng. Pat. 112,336 of 1917; this J., 1918, 94A.

Classifier. U.S. Pat. 1,260,135. See I.

Recovering sulphur dioxide or the like from gases containing the same. Apparatus for segregating and recovering gases. U.S. Pats. 1,260,492 and 1,260,493. See VII.

Making articles from blast-furnace slag. U.S. Pat. 1,259,304. See IX.

Cement for pickling-vats. U.S. Pat. 1,259,651. See IX.

XI.—ELECTRO-CHEMISTRY.

Storage battery capacities; Calculation of —. C. W. Hazlett. Amer. Electrochem. Soc., Apr.-May, 1918. [Advance copy.] 13 pages.

The capacity of any Faure or pasted-type starting battery cell between the limits of the 5-minute and 100-hour rates of discharge, and of all commercial type vehicle plates between the 30-minute and 12-hour rates, is a definite single function of the time, i.e.,

$$\log I + f(T)(\log T) = K,$$

where I is the current, T the time, K the capacity in ampere-hours, and $f(T)$ a definite function of the time. The formula

$$E = 1.85 - \frac{0.448}{\log T},$$

where E is the final voltage and T the time rate of discharge in minutes, is offered as a scientific and practical universal final-voltage equation. The charging and finish-charging rates of any cell should be a definite time rate of discharge, and the 7- and 18-hour rates respectively are recommended. The development of an alignment chart and circular slide rule for calculating storage battery capacities at various time rates of discharge is shown.—B. N.

[Electric] cell; An experimental carbon —. S. A. Reed. Amer. Electrochem. Soc., Apr.-May, 1918. [Advance copy.] 6 pages.

A PRIMARY battery is described in which the electrolyte is fused borax containing manganese dioxide, the negative is broken carbon in contact with a graphite grid floating on the melt, and the positive poles are strips of gold foil. The carbon is placed inside a cylindrical shell of siliceous material (a crucible with the base cut off), and supported in a shallow clay roasting dish containing the melt. The electrolyte in contact with the outer gold strips is oxidised, whilst the inside electrolyte is reduced by the carbon anode, forming a mixture of carbon dioxide and monoxide. An average voltage of 0.8 is produced at a temperature of 925°–990° C.—B. N.

Lead electrode; The —. F. H. Getman. J. Amer. Chem. Soc., 1918, 40, 611–619.

Cast lead, electrolytic lead, and lead amalgam give the same potential, measured in a saturated solution of lead chloride at 25° C., but lead strips which had been immersed in Heller's solution (460 grms. $Pb(NO_3)_2$, 1000 c.c. water, and 100 c.c. HNO_3 of sp. gr. 1.16) exhibited a potential 8 millivolts higher than the others. This confirms the existence of an allotrope of lead. From the results it is calculated that the heat of the reaction $Pb + Hg_2Cl_2 = PbCl_2 + 2Hg$ is 21,840 cals. and the heat of formation of lead chloride is 84,400 cals. (See also J. Chem. Soc., 1918, ii., 181.)—J. F. S.

Manganese in sulphate solutions; Electrolytic behaviour of —. G. D. van Arsdale and C. G. Maier. Amer. Electrochem. Soc., Apr.-May, 1918. [Advance copy.] 16 pages.

The current efficiencies, voltages, and conditions affecting the nature of deposits formed during the electrolysis of manganese sulphate solutions have been studied, and it is shown that manganese may be deposited at the cathode from neutral solutions with high current efficiency (from 80–90%) at voltages from 3 upwards. The deposit is powdery, and ordinary expedients for improving deposition do not give better results to any extent. The deposi-

tion of manganese is diminished by increase of acidity, and is entirely prevented by 0.36% of free sulphuric acid. Manganese dioxide may be deposited at the anode at nearly 100% efficiency, and, though the effect of acid is to decrease the efficiency in cold solutions, there is much less effect on heating to 65°–75° C. Manganese dioxide is deposited from warm acid solutions containing more than 5% of manganese sulphate in the form of a dense, black, lustrous film, at current densities up to 275 amperes per sq. m. with very high deposition efficiency. Impurities such as ferrous iron and thionates cause a decrease in current efficiency according to the amount present.—B. N.

Passivity of chromium. Atch. See X.

PATENTS.

[Electrolytic] gas generators. C. F. Euler, Topeka, Kans., U.S.A. Eng. Pat. 114,491, Apr. 13, 1917. (Appl. No. 5272 of 1917.)

SEVERAL horizontal electrodes are supported by a non-conducting tank near its base, and are spaced vertically apart, extending substantially the length of the tank. A wire screen electrode is supported a suitable distance above, extending over substantially the entire area of the tank. (See also U.S. Pat. 1,234,319; this J., 1917, 1053.)—B. N.

Gas; [Electrolytic] process of making —. F. A. Osowski, Detroit, Mich. U.S. Pat. 1,259,898, Mar. 19, 1918. Date of appl., Sep. 28, 1917.

THE electric circuit is provided with spaced terminals forming a gap, and a measured quantity of acidulated water is fed, drop by drop, between the terminals to bridge the gap. Each drop, forming a conductor for the current, is decomposed by the current flowing through it.—B. N.

Depolariser; Battery —. M. E. Holmes, Lakewood, Ohio, Assignor to National Carbon Co., Inc. U.S. Pat. 1,259,099, Mar. 12, 1918. Date of appl., Sep. 10, 1914.

PIROLYSITE is purified and its depolarising action, when used in electric batteries, increased, by heating it in a hydroxide solution under pressure.—B. N.

Electrode; Storage battery —. T. Spencer, Philadelphia, Pa., Assignor to National Carbon Co., Inc., Cleveland, Ohio. U.S. Pat. 1,260,472, Mar. 26, 1918. Date of appl., Aug. 21, 1915.

A porous framework of a phenolic condensation product is formed as a filling in a grid, and active material is introduced into the pores of the filling.—B. N.

Electrode holder for electric furnaces. P. Fischer, Chicago, Ill. U.S. Pat. 1,259,842, Mar. 19, 1918. Date of appl., June 8, 1917.

A holder for an electric furnace electrode is provided with a tubular shank surrounded by a water jacket, the cooling water passing around and through the bore of the tubular shank. To one end of the electrode is fastened a metal reinforcing member comprising a tubular portion surrounding one end of the electrode and another portion extending beyond the end of the electrode, both the latter portion and the adjacent end of the electrode being provided with a continuous tapering bore. The end of the holder is tapered to correspond with the bore and fits into the latter, the tip of the holder-end being provided with a raised thread engaging adjacent portions of the electrode.—J. F. B.

Furnaces; Phase distribution for electric —. T. F. Baily and F. T. Cope, Assignors to The Electric Furnace Co., Alliance, Ohio. U.S. Pat. 1,260,298, Mar. 26, 1918. Date of appl. Jan. 31, 1918.

A HIGH-TEMPERATURE heating and a low-temperature reheating furnace are each furnished with a pair of resistance elements and supplied with current from a 3-phase supply. One of the supply wires is connected to each of the resistance elements in the heating furnace, the second supply wire to one of the resistance elements in the reheating furnace and to both elements in the reheating furnace, whilst the third wire is connected to the other resistance element in the heating furnace and to both elements in the reheating furnace.—B. N.

Electric furnaces. J. L. Dixon, Detroit, Mich., U.S.A. Eng. Pat. 111,103, Oct. 15, 1917. (Appl. No. 14,932 of 1917.) Under Int. Conv., Oct. 14, 1916.

SEE U.S. Pat. 1,214,763 of 1917; this J., 1917, 389.

XII.—FATS; OILS; WAXES.

"Acid oils" and soap stocks; Determination of moisture and total fatty matter in —. E. R. Bolton and C. Revis. Analyst, 1918, 43, 158–161.

"Soap stock" is the product obtained when edible fats and oils are treated with alkali to remove free fatty acids; it contains a varying proportion of neutral oil entrained in the soap. If this product is decomposed with a mineral acid or nitric acid, the mixture of neutral oil and fatty acids obtained constitutes "acid oil." To determine moisture in "acid oil," a strip of filter paper, 15 in. long and 1.25 in. wide, is pleated in $\frac{1}{2}$ in. folds, loosely curled, placed in a weighing bottle, and dried for 48 hours over sulphuric acid in a vacuum desiccator. The bottle and coil are then weighed, 20 to 30 drops (0.7 to 1.0 gm.) of the oil are dropped on the upper edges of the coil, and, after re-weighing, the bottle and its contents are again dried in the desiccator as before. The desiccator should be kept at such a temperature (say 30° C.) that the oil remains liquid. To determine total fatty matter in soap stock, from 1 to 2 grms. of the sample is mixed with 20 c.c. of hot water and sufficient hydrochloric acid to decompose the soap, the mixture is heated gently under a reflux condenser until the fatty acids separate in a clear layer, the mixture then cooled, and the fatty layer separated by means of a mixture of equal parts of ether and petroleum spirit. The ethereal extract is evaporated, the residue of fatty substance dried in the water-oven, and weighed. A special flask is described in which the soap stock is decomposed and extracted.—W. P. S.

Shark liver oil; A highly unsaturated hydrocarbon in —. M. Tsujimoto, Kōgyō-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1917, 20, 953–1017, 1069–1098. (See also this J., 1916, 609, 1121; 1918, 98; also Chapman, this J., 1917, 392.)

SEVERAL samples of shark liver oil obtained from 27 species of sharks caught in Japanese waters have been investigated. The oils have been classified in two groups: (1) those with sp. gr. below 0.9000 at 15°/4° C., and (2) those with sp. gr. above 0.9000 at 15°/4° C. The shark liver oils of the first group, most of which are derived from sharks of the family *Squalidae*, are all rich in the hydrocarbon squalene (*loc. cit.*), $C_{30}H_{50}$, whereas the oils of higher sp. gr. are free from squalene, with the exception of Karasuzame oil (10%) and Fujikujira (*Etmopterus lucifer*) oil (1%). The hexahydrohalogen compounds of squalene are easily

obtained by passing the dry hydrogen halide into a cooled ethereal solution and recrystallising from acetone. The hexahydrochloride sinters at 110° C. and melts clear at 125° C. with separation of hydrogen chloride; this compound may be used for the detection of squalene, even as little as 1%. The hydrobromide is very similar; the hydriodide is not so easily obtained, and melts to a pink liquid at 108°–109° C. The oils of the first group are characterised by high iodine values and low saponification values. By eliminating the elements of hydrogen chloride from the hexahydrochloride by treatment with zinc and acetic acid, a viscous liquid corresponding to $C_{30}H_{50}O_2$ is obtained. On destructive distillation a hydrocarbon resembling myrcene is obtained. The specific viscosity of squalene in Ostwald's viscosimeter is 14.3 at 15° C. and 12.2 at 25° C., and the time of flow by Redwood's viscosimeter is 91 secs. at 15° C. and 73 secs. at 25° C. For the determination of hydrocarbon (squalene) in shark liver oil, 50 grms. of the oil is distilled under 10 mm. pressure, and the acid value of the distillate, calculated as fatty acid, is deducted from the weight of distillate, the remainder being the approximate quantity of hydrocarbon. Aizame (*Centrophorus* sp., described previously as *Squalus mitsukurii*) oil is exceptionally rich, containing 84.8% of squalene. —J. F. B.

Dog-fish liver oil. A. C. Chapman. Analyst, 1918, 43, 156–158.

THE liver of the common dog-fish (*Squalus acanthias*) yields, when minced and steamed, about 40–50% of its weight of a pale yellow oil, which becomes semi-solid at 10° C. owing to the separation of solid glycerides. Two specimens of the oil prepared from different batches of liver had the following physical and chemical characters, the analyses having been made after the oils had been cooled and the solid substance separated:—Sp. gr. at 15°/15° C., 0.9175, 0.9186; refractive index at 20° C., 1.4755, 1.4749; optical rotation in 100 mm. tube, —, —1.45; saponif. value, 161.0, 168.3; iodine value (Wijs), 123.3, 123.0; free fatty acids (as oleic acid), 0.33%, 0.42%; unsaponifiable matter, 32.94%, 9.48%; brominated glycerides insoluble in ether, 19.25%, 24.95%. The proportion of unsaponifiable matter in the oil appears to depend on the age and condition of the fish.—W. P. S.

Lipase; Action of acids on castor seed —. G. Kita, Kōgyō-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1918, 21, 1–4.

ARMSTRONG (this J., 1905, 1242) found that the lipolytic activity of castor seed from which the fat had been removed was destroyed by a quantity of acid equal to that which exercised the most favourable effect on the enzymic hydrolysis of fats, and hence concluded that the favourable effect of the acid cannot be due merely to its stimulating action on the enzyme. According to the author the explanation of this apparent anomaly lies in the fact that whilst lipase rendered active by a small quantity of acid loses its activity in presence of an additional quantity of acid, in presence of fats the sensitiveness of the activated enzyme to acid is markedly diminished.

Gossypol, the toxic principle of cotton seed. Carruth. See XIXA.

PATENTS.

Oily materials; Process of purifying —. W. P. Schuck, Assignor to Superior Oil and Process Co., Portland, Oreg. U.S. Pat. 1,250,072, Mar. 19, 1918. Date of appl. Aug. 31, 1916.

FATTY oils are purified by distilling off at least some of the impurities in a current of hydrogen, in

absence of hydrogenising catalysts, whilst maintaining the oil at about 300° C., a free exit for the gas carrying off the volatilised impurities being maintained.—A. de W.

Press plates for oil expressing presses and analogous apparatus. A. W. French, Plqua, Ohio, U.S.A. Eng. Pat. 111,855, Dec. 3, 1917. (Appl. No. 17,894 of 1917.) Under Int. Conv., Dec. 2, 1916.

Soap; Apparatus for and method of rapidly ageing —. De N. W. B. Young, Narberth, Pa., U.S.A. Eng. Pats. 114,878 and 114,879, Apr. 13, 1917. (Appl. Nos. 5242 and 5243 of 1917.)

See U.S. Pats. 1,246,515 and 1,250,540 of 1917; this J., 1918, 47 A, 130 A.

Separating liquids of different specific gravity insoluble or difficultly soluble in each other, such for instance, as an emulsion or mixture of grease and water. Eng. Pat. 114,921. See I.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Sulphite turpentine Schorger. See V.

PATENTS.

Sulphide of zinc; Process for the preparation of anhydrous —. P. Comment, Dijon, France. Eng. Pat. 114,407, May 9, 1917. (Appl. No. 6596 of 1917.) Under Int. Conv., Mar. 28, 1917. Addition to Eng. Pat. 106,489 (this J., 1918, 273A).

Zinc persulphide to be used for reducing anhydrous zinc sulphate to sulphide as described in the chief patent may be obtained by dehydrating the zinc pentasulphide resulting from the action of an alkali or alkaline-earth pentasulphide on a zinc salt. Sulphur may also be present, with the persulphide, and effects a similar reduction. The addition of an alkali sulphate may be avoided by calcining the mixture for 3 hours at 500°–600° C., and then for 1 hour at 800°–900° C. The process may also be modified by the substitution of zinc sulphite for zinc sulphate. Barium sulphate may also be added in any desired proportion to obtain lithopones.—W. F. F.

Red pigment ["Crimson antimony" or "antimony vermilion"]; Manufacture of —. E. F. Morris, Roby, and T. N. C. Nevill, St. Helens, Lancs. Eng. Pat. 114,581, Oct. 17, 1917. (Appl. No. 15,025 of 1917.)

Basic antimony sulphate is used in place of the normal sulphate in the preparation of "antimony vermilion" or "crimson antimony" by precipitation with sodium thiosulphate.—A. de W.

Lampblack [and hydrochloric acid, from natural gas]; Process of manufacturing —. W. R. Mott, Lakewood, Ohio, Assignor to National Carbon Co., Inc. U.S. Pat. 1,259,121, Mar. 12, 1918. Date of appl., June 24, 1916.

Chlorine and methane or natural gas are admitted into a heater to form carbon tetrachloride and hydrochloric acid. The resulting products are admitted to a mixer with more methane or natural gas and forced into a heater to form lampblack and hydrochloric acid, the hydrochloric acid and excess of natural gas being withdrawn through a condenser to condense the former, and the excess of natural gas then led into the stream of natural gas entering the mixer.—A. de W.

Ink; Solid —. P. Akashi, Tokyo, Japan. Eng. Pat. 114,601, Dec. 21, 1917. (Appl. No. 18,941 of 1917.)

A PLASTIC or pasty composition forming a permanent solution when dissolved in water and which will

not dry up or harden on keeping, is prepared with the aid of a mixture of thymol and lactic acid. A suitable composition for ink may be made from dye (e.g., Methylene Blue), 25 parts; dextrin, 5 parts; gum tragacanth mucilage, 4 parts; thymol, 2–3 parts; and lactic acid, 3–4 parts, all by weight. —A. de W.

Phenolic condensation products; Composition containing —. Process of moulding articles. L. H. Baekeland, Yonkers, N.Y., Assignor to General Bakelite Co., New York. U.S. Pats. (A) 1,259,472 and (B) 1,259,473, Mar. 19, 1918. Dates of appl., Dec. 2, 1909, and May 25, 1917.

(A) AN infusible composition, particles or fragments of which can be welded by heat and pressure to compact coherent masses, consists of a phenolic condensation product in solid solution with a fusible cyclic hydrocarbon of high boiling point, insoluble in water. (B) Coherent masses or articles are produced from a final infusible phenolic condensation product by compounding it with a material imparting to the mass the capability of welding, subdividing this product, and then consolidating the fragments by heat and pressure.—A. de W.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Caoutchouc; Depolymerisation of raw —. S. Takeuchi, Kōgyō-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1917, 20, 1297–1309.

The degree of depolymerisation of raw caoutchouc which takes place during mastication has been studied by measuring the absolute viscosity of solutions of 1 grm. of caoutchouc in 70 c.c. of benzene. Samples from *Urecola* and *Hevea*, wild and cultivated, were investigated. This determination serves as a very convenient control of the time of mastication and other operations. The mastication should be carried on until the absolute viscosity of the solution reaches about 0.1. The solubility in acetone of the resin or other acetone-soluble matter changes during mastication, and shows a minimum value when the viscosity reaches about 0.1.—J. F. B.

PATENTS.

Rubber conglum or similar material and process for preparation of the same for vulcanisation. E. M. Slocum, Medan, Sumatra, Assignor to General Rubber Co. U.S. Pats. (A) 1,259,793 and (B) 1,259,794, Mar. 19, 1918. Date of appl., Jan. 8, 1917.

(A) LATEX is treated with a naphthol, all the solid constituents of the latex being thereby substantially conserved. (B) Rubber conglum, before the incorporation of sulphur, is subjected to the action of β -naphthol so as to form a semi-permeable layer over the nitrogenous material in the rubber and thus prevent its migration.—D. F. T.

Plastic [rubber] composition. F. J. Tone, Assignor to The Carborundum Co., Niagara Falls, N.J. U.S. Pat. 1,259,806, Mar. 19, 1918. Date of appl., Sep. 23, 1915.

A PLASTIC composition is made containing rubber mixed with silicon monoxide.—D. F. T.

XV.—LEATHER; BONE; HORN; GLUE.

Tanning; Lyotropic series and theory of —. H. G. Bennett, J. Soc. Leather Trades' Chem., 1917, 1, 130–136 and 169–182.

DISSOLVED substances fall into a definite sequence when arranged in the order of their effects on the physical properties of water and on its properties

as solvent and as a dispersion medium for colloid sols. This sequence is known as the lyotrope series, and its influence in various processes of leather manufacture is pointed out. Lyotrope influence has a marked effect on the imbibition of the hide gel, and a considerable though less effect on the gelation or diffusion of the tannin sol. The active surface of swollen hide or hide powder is of predominant importance for the adsorption of tannin, and largely depends on the lyotrope influence of salts, etc., present. Consequently the addition of non-tanning substances (such as glucose or magnesium sulphate) to a tannin solution causes considerable variations in the amount of tannin shown by analysis. The first stage of the vegetable tanning process is adsorption, and the amount of tannin adsorbed is a function of the specific surface of the adsorbing hide. The next stage consists in the diffusion of the tanning sol into the hide gel (there also lyotrope influence exerts an effect), and the gelation of the tanning sol at the interface of sol and hide fibre. Either of these two phenomena may predominate. Another essential part of tanning is the co-precipitation of the two oppositely charged colloids, the positive hide (in acid) and the negative tannin. Chrome tannage is essentially the same as vegetable tannage. Lyotrope influence is more marked, but exerted in the same sense, *i.e.*, the imbibition of the hide gel is reduced. There is the same sequence of lyotrope influence, adsorption, gelation, and diffusion of the sol, and precipitation of the sol at the hide fibre surface. The author does not regard tanning as an "irreversible" phenomenon.—F. C. T.

Gelatin: The swelling of — H. G. Bennett.
J. Soc. Leather Trades' Chem., 1918, 2, 40—51.

OWING to the contractile force of surface-tension the surface layer of a liquid is a zone of compression. If the surface is greatly increased by the presence of a large number of small particles the compression of the water becomes correspondingly greater. In the case of a colloid sol, such as a gelatin solution, there is a zone of compression surrounding each particle, and increased concentration causes the approach of these zones and final overlapping. Thus at first there is increase in viscosity, and subsequently setting. A jelly swells by reason of the mutual repulsion of similarly charged particles, the charges being due to the adsorption of ions. The swelling force varies inversely as the square of the distances separating the particles, *i.e.*, inversely as the cube root of the square of the volume. Thus the contractile force, or force tending to resist swelling, and the swelling force both diminish as swelling proceeds and the volume increases, but the swelling force diminishes with the greater rapidity, though much the larger at the outset. Finally the force of repression equals the swelling force and there is no further increase in volume.—F. C. T.

Gelatin: The swelling of — H. R. Procter.
J. Soc. Leather Trades' Chem., 1918, 2, 73—76.

This paper is in reply to one by Bennett (see preceding abstracts). The use of terms such as adsorption, lyophilic, lyotrope, etc., does not explain anything, since Bennett does not show their relation to understood physical or chemical processes. Further, Bennett's explanations are purely qualitative, whereas Procter and Wilson (this J., 1916, 645; 1917, 92) account quantitatively for the phenomena of swelling. Bennett's contention that jellies are two-phased structures is merely a matter of terms, since everything is two-phased in a molecular sense. In a gelatin jelly, however, even the ultramicroscope gives no proof of structure. The

statement that the internal pressure of a liquid is due to surface-tension is vigorously contested. Actually the surface-tension is a consequence of the internal pressure, which in its turn is caused by molecular attraction. The attraction drawing a particle of liquid inwards is a maximum at the surface, but the compression is a minimum as there is no superincumbent liquid. At interfaces of contact with solid or other liquid particles the tensions may be zero or negative. No experimental condensations of liquids by pressure or addition of soluble salts have resulted in large increases of viscosity. Whereas Procter and Wilson attribute the swelling of gelatin to the osmotic pressure or kinetic energy of ions associated with the colloid, Bennett ascribes it to static electrical repulsion of similarly charged colloid particles. Such particles, however, will not repel each other, as their charges will be balanced by a surface layer of ions of opposite charge, the whole complex being electrically neutral. Agreement is expressed with Bennett's view of the practical importance of the lyotrope series in tanning.—F. C. T.

Chrome liquors: Alteration in basicity during tannage of hides in one-bath — C. F. Barber and P. R. Barker. J. Soc. Leather Trades' Chem., 1917, 1, 142—144.

FOUR series of liquors were used, the first made from chrome alum, the second by the reduction of bichromate with glucose, the third from a ready-made one-bath liquor, and the fourth made from bichromate by reduction with bisulphate. Each series consisted of several liquors of different basicities. During tannage the basicity sometimes remained constant, sometimes diminished, and occasionally increased. No general rule appears to be followed. The results are given in detail in the paper.—F. C. T.

Leather: Wear resistance of — from different parts of the hide. F. P. Veitch and J. S. Rogers. J. Amer. Leather Chem. Assoc., 1918, 13, 86—90.

A LARGE number of soles were tested in actual wear on boys' sandals. Leather from butts wore twice as long as leather from bellies and one and one-third times as long as that from shoulders.—F. C. T.

[Tannery] lime liquors: Determination of ammonia in used — F. C. Thompson and K. Suzuki. J. Soc. Leather Trades' Chem., 1917, 1, 140—142.

CYSTINE is decomposed by magnesia at 100° C., yielding ammonia, and its probable presence in used lime liquors points to a likely source of error in the ordinary method of determining ammonia. Distillation of the neutralised liquor with magnesia *in vacuo* at any temperature below 40° C. (when cystine is unattacked but ammonium salts easily decompose) gives lower results than the ordinary method, the difference being usually about 5% of the ammonia found.—F. C. T.

Egg yolks: Estimation of fat in commercial — M. C. Lamb and A. Harvey. J. Soc. Leather Trades' Chem., 1917, 1, 186—187.

ADAM's method for the estimation of fat in milk is adopted. The egg yolk is spotted on an Adam's paper, or on a strip of coarse fat-free filter paper. The paper is dried overnight at the ordinary temperature and then extracted as usual in a Soxhlet apparatus. The advantage of the method is in its convenience. Accurate results are obtained.

—F. C. T.

PATENTS.

Hides and skins; Process of tanning —. L. T. Hall and F. Tuttle, Houston Heights, Tex. U.S. Pat. 1,256,789, Feb. 19, 1918. Date of appl. Mar. 25, 1916.

HIDES are tanned by an infusion of tillandsia. —F. C. T.

Leather; Process of producing artificial —. C. E. Arnold, Assignor to E. I. du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 1,257,665, Feb. 26, 1918. Date of appl., Sep. 3, 1914. Renewed July 9, 1917.

ONE or more coats of a plastic nitrocellulose composition are applied to a fabric with the aid of pressure. —F. C. T.

Leather; Process for producing artificial —. F. Sparre, Assignor to E. I. du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 1,257,756, Feb. 26, 1918. Date of appl., Sep. 3, 1914. Renewed July 10, 1917.

ONE or more coats of nitrocellulose composition in the form of a jelly are applied to a fabric and each coat subsequently dried. A coat of cementing material is then applied, and before this is dry a coat of nitrocellulose plastic material is applied with the aid of pressure. —F. C. T.

Glue; Process of manufacturing vegetable — [from starch]. V. G. Bloede, Catonsville, Md. U.S. Pat. 1,257,307, Feb. 26, 1918. Date of appl. Oct. 29, 1917.

A STARCH base is treated with caustic alkali, then partially or completely neutralised, and subsequently reduced to the required consistency either by the action of ferments or enzymes or by dilution with a thin vegetable glue produced from starch by such ferment action. —F. C. T.

Hides, skins, and the like; Machine for facilitating the handling and treatment of — in tanning and like operations. The Vulcan Engineering Co. (Whitehaven), Ltd., and A. Dickson, Whitehaven. Eng. Pat. 115,009, Jan. 29, 1918. (Appl. No. 1665 of 1918.)

XVI.—SOILS; FERTILISERS.

Zeolitic silicic acid in soils; Determination of —. K. K. Gedrovic. Reprint, pp. 400—406.

THE following method for determining zeolitic silicic acid, i.e., that liberated when a soil is treated with concentrated hydrochloric acid, gives good results, is rapid, and obviates the necessity for using large platinum dishes. Five grms. of the soil is treated in a small platinum dish with 10% hydrochloric acid and then calcined over a gas burner furnished with a movable mushroom-shaped top perforated over its whole surface; the temperature of the soil should not exceed 625° C. When the organic matter has been completely destroyed, the soil is cooled, mixed in a beaker with water and with 100 c.c. of 5% potassium hydroxide solution. The liquid is then heated for half an hour on a water-bath and subsequently filtered, the first opaque portion of the filtrate being returned to the filter. The contents of the latter are washed ten times with 1% potassium hydroxide solution and the total filtrate acidified with hydrochloric acid and evaporated to dryness on a sand-bath at 125°—150° C., this requiring 1—1½ hour. The silicic acid, thus rendered quite insoluble, is washed and filtered; it should be free from chlorine. —T. H. P.

Bracken as a source of potash. R. A. Berry, G. W. Robinson, and E. J. Russell. J. Rd. Agric., 1918, 25, 1—11.

YOUNG bracken yields the purest ash, containing just over 50% K₂O, but the total yield of potash per acre is only about 20 lb. Fully-grown bracken yields a less pure ash, containing from 30—40% K₂O, but the yield of potash per acre may be 200 lb. or more. When the plant dies and shrivels, however, the potash becomes lost, part returning to the root and part being washed away by the rain. At the fully-grown stage the yield of potash per acre will vary somewhat with the class of soil, but is largely controlled by the relative luxuriance of growth and close packing on the ground. The best time to harvest is July or August, and it is estimated that one ton of bracken ash would be obtained from 7—10 acres of land. Making approximate estimates, the cost of collection of one ton of ash would be from 12*l.* to 15*l.*, and its value, taking potash at 10*s.* per unit, would be 15*l.* to 20*l.*, assuming that all the ash was saved and none exposed to rain. Probably the best way wherever possible is to use the bracken for litter or bedding, thus obtaining the potash and also nitrogen and organic matter, and at the same time liberating straw for other purposes. —W. G.

PATENTS.

Cyanamide and like silos; Construction of —. O. Svendsen, London. Eng. Pat. 114,487, Apr. 11, 1917. (Appl. No. 5119 of 1917.)

A SILO, when of rectangular form, is constructed with a series of sloping shelves, one above the other, along two opposite sides, and a double series along the centre, arranged so as to slope towards the shelves on the sides at an angle slightly greater than the angle of repose of the material to be stored. Hoppers are provided at the top, opening over the space between the sloping shelves. The silo is emptied from the bottom. When the silo is of cylindrical construction the central shelves are of circular form, supported on a central pillar, and placed intermediately with the shelves on the wall. The spaces under the shelves permit of expansion of the material, e.g., crude calcium cyanamide, being stored. —J. H. J.

Calcium cyanamide; Process of making —. G. E. Cox, Niagara Falls, N.Y., Assignor to American Cyanamid Co., New York. U.S. Pat. 1,258,747. Mar. 12, 1918. Date of appl., Dec. 19, 1917.

FINELY-DIVIDED calcium carbide is heated to a reacting temperature and nitrogen passed over it at a constant rate. When the reaction begins, the heat applied is decreased and is maintained at the lower level until the reaction is self-propagating. The reaction is allowed to go on until practically all the mass is converted into cyanamide.

—J. H. J.

Phosphate fertilizer containing nitrogen; Manufacture of a —. F. W. Howorth, London. From Norsk Hydro-Elektrisk Kvaestofaktieselskab, Christiania, Norway. Eng. Pat. 114,873, Apr. 10, 1917. (Appl. No. 5062 of 1917.)

AN intimate mixture of raw phosphate and calcium carbonate is treated with sufficient dilute nitric acid to render the bulk of the phosphate soluble and to form a product which solidifies to a hard, dry mass on cooling. For example, by treating a mixture of apatite (920 kilos., containing 72% of tricalcium phosphate) and limestone (80 kilos.) with nitric acid of 62% strength (790 litres), a product (1850 kilos.) is obtained containing over 15% of soluble phosphoric acid and about 6.5% of nitrogen. Conservation of the nitrous gases is effected by con-

ducting the process in a closed vessel and subjecting the liquid product to the action of a vacuum or compressed air.—W. E. F. P.

XVII.—SUGARS; STARCHES; GUMS.

Sugar; Balance of some constituent principles of the sugar-beet during the manufacture of —.

E. Saillard. *Comptes rend.*, 1918, 166, 697–699.

AVERAGE figures are given for twenty factories over a period of fifteen years for the distribution of the dry matter, nitrogen, potash, soda, and phosphoric acid of the beetroot, in the diffusion pulps and water, the carbonatation cakes, the molasses, and the condenser water. The nitrogen in the condenser water is about 17% of the total and is lost. That in the molasses is about 30% of the total and is generally lost in the manufacture of alcohol from the molasses. Almost the whole of the potash and soda are found in the molasses, whilst most of the phosphoric acid is found in the carbonatation cakes.

—W. G.

Sugar boiling in Hawaii. A. Giacometti. *Intern. Sugar J.*, 1918, 20, 182–185.

IN the two-boiling system, which is now most generally used in Hawaii, a magma of second sugar and syrup is charged into the pan; syrup is boiled upon it until the pan is full; one half is transferred to a second pan; and the two "strikes" finished with more syrup and molasses. After curing the massecluites with very little or no washing, the sugar is bagged without drying. By the regulation of the quantity of "seed" in the first charge, the desired size of the finished grain is determined, and much care must be exercised in preparing this "seed footing" before proceeding to the actual boiling, since any neglect in eliminating false grain at this stage of the process will result in a poor sugar. When boiling second-grade sugars, a charge of first molasses is drawn into the pan to about one-fourth of its capacity, boiled to string-proof, and dropped into a tank. As soon as enough crystals are formed, which generally occurs after 18–24 hours, the charge is taken back into the pan, and finished with the same grade of molasses. Alternatively, this period of crystallisation at rest may be dispensed with, the molasses being grained directly in the pan; but in either case boiling must be very slow to ensure good exhaustion, and cooling should be carried out in crystallisers alone or in crystallisers and tanks for about equal periods. Complaints have been made by refineries in the United States against the small and uneven grain of Hawaiian sugar, so troublesome in refining, but by insisting upon the careful elimination of false grain in the early stage of boiling this defect has been remedied. Attention is now being given to the high ash content of the sugar. Contrary to the general belief, the greater part of the ash is not present in solution in the molasses adhering to the crystals, but is held by the sugar in the solid form. Washing the sugar in centrifugals and afterwards remelting is insufficient, and the suspended solids must be eliminated by decantation or filtration. Sugars of lower ash content would be obtained by sulphiting the thick-juice to neutrality and filtering to remove the calcium salts; the formation of incrustation in the pan would also thus be prevented, or at least much diminished.—J. P. O.

Molasses; Geerligns' theory of the formation of — and experiments upon the precipitation of sucrose from exhausted molasses by acetic acid. H. C. Prinsen Geerligns. *Intern. Sugar J.*, 1918, 20, 168–170.

ACCORDING to the author's theory (*Archief Java Suiker-ind.*, 1895, 297; this J., 1895, 667), final

molasses may be regarded as a hydrated combination of sucrose, reducing sugars, and salts, analogous to the known double compounds of sodium chloride and sucrose or calcium chloride and kevalose, from which the constituents do not separate out on further concentration of the solution. Experiments are now described controverting the view that molasses is simply a solution of sucrose in non-sugars. Alcohol was added to a solution of sucrose and sodium chloride in water, in such proportion that the sucrose present would have remained dissolved and the salt would have been precipitated had either of these constituents been present alone in the solution. It was found, however, that the solution separated into two layers, both consisting of sucrose, sodium chloride, water, and alcohol, with the same relative proportions of sucrose and sodium chloride in both. A similar result was obtained in the case of cane molasses; whereas were molasses simply a solution of sucrose in non-sugars, it would seem certain that the relative proportions of sugars and salts would thereby have been changed. The observation of Friedrich (this J., 1917, 1187) that on mixing beet molasses with an equal weight of glacial acetic acid, about 56% of the sucrose of the molasses (or about 72% of the total sugar present) is precipitated in the form of a tolerably white powder, is confirmed, and this result is regarded as proof of the existence of a sucrose-salts combination, decomposable on the addition of an acid. Cane molasses failed to yield a parallel result, possibly because in this case the reducing sugars are too strongly combined with the salts to be liberated by acetic acid. If a stronger acid, e.g., hydrochloric, be added, the combination appears to break up, for the alcohol was found to precipitate the salt fraction, or at least part of it, from cane molasses, the sucrose and reducing sugars remaining dissolved.—J. P. O.

Decolorising carbons; Vegetable — [for sugar refining]. M. A. Schnell. *Louisiana Planter*, 1917, 64, No. 10, 154–156.

A MIXTURE of three parts of sawdust and two of lime when charred and heated to 600°–1000° C. or over produced a carbon of the efficiency of "Norit" (see this J., 1918, 160A), but the process is a costly one, owing to the fact that the product contains much calcium carbonate, which must be eliminated by solution in hydrochloric acid and washing. Processes using water-soluble substances as potassium carbonate or calcium chloride in the mixture that is carbonised are cheaper, and these were found to give carbons having 70–80% of the decolorising power of "Norit." In Louisiana rice hulls or leaves are carbonised with the exclusion of air in a closed iron retort at red heat, when a product is obtained containing about 50% of mineral matter, mostly silica. By dissolving out the silica enveloping the carbon, using about 20% of caustic soda, a material is produced having about 1½ times the decolorising power of "Norit." (See also this J., 1917, 1041.) None of the other methods tried, however; approaches the zinc chloride process of Zelnicek (Austrian Patent 3718), the underlying principle of which appears to be the carbonisation of the organic matter with the aid of dehydrating substances at a low temperature before the furnace heat can destroy the porosity of the material. Thus, a mixture of 2 parts of zinc chloride and 1 of sawdust was evaporated with water and heated in a retort to the volatilisation point of the salt, when a carbon was obtained having a decolorising power three times as great as that of "Norit" (the decolorising power of which is 10–30 times that of ordinary animal charcoal); while a 3 to 1 mixture of these two ingredients produced a carbon five times more active than "Norit."—J. P. O.

Corrosion in an evaporator of a sugar factory in Java caused by organic acids formed from the juice. T. A. Jentink. *Archief Suiker-ind. Ned.-Indië*, 1917, 25, 29–31. *Intern. Sugar J.*, 1918, 20, 191–195.

In a factory in Java operating according to the sulphitation-defecation process the brass tubes of the multiple-effect evaporator were strongly corroded, especially in the second and the third effects. Suspecting that this was due to sulphurous acid volatilised from the juices, daily titrations of the condensed waters from the several effects with $N/50$ iodine and $N/50$ sodium hydroxide solutions were made during a fortnight, parallel observations being also carried out in a factory working normally. In the factory troubled with corrosion, the acidity of the condensed waters was considerably higher in the case of the fourth or last effect and lowest in the second; whereas normally it is constant in each effect. On the other hand, the iodine titration was highest in the water from the second effect and lowest in the fourth. If the corrosion had been caused by sulphurous acid, the iodine titration would have been highest in the case of the fourth effect, in which by far most corrosion had occurred. It is suggested that, probably owing to insufficient clarification, there were present in the juice volatile organic compounds of ketonic or aldehyde nature, methylglyoxal, for example, which became oxidised during evaporation. As concentration proceeded the content of these compounds in the condensed water (as indicated by the iodine titration) fell, while concurrently acids, probably mostly glyoxylic acid, were formed, and accumulated principally in the last effect of the multiple evaporator.—J. Sugar solutions; Material for clarifying — and means for regenerating the material after use. T. Hayashi, U. Emura, and Kwantō Sanso Kabushiki-Kaisha, Ltd., Tokyo, Japan. Eng. Pat. 108,303, May 18, 1917. (Appl. No. 7175 of 1917.) Under Int. Conv., July 22, 1916.

A solution of commercial phosphoric acid of 13–20% strength is freed from excess of free sulphuric acid by heating with 3–10% of aluminium or 5–13% of aluminium hydroxide. The greater part of the water is then removed by vacuum evaporation, and the concentrated phosphoric acid is mixed with powdered bone-black to a pasty consistence. The product is used for the clarification of sugar solutions after defecation with lime. The carbon may be regenerated by washing with a solution of phosphoric acid, either directly or, if highly charged with impurities, after burning or boiling with caustic soda.—J. F. B.

Bagasse, etc.; Process of preserving — and making fuel therefrom. Process for economic steam production in cane-sugar factories. W. Geveke, New York, U.S. Pats. (a) 1,258,888 and (b) 1,258,889, Mar. 19, 1918. Date of appl., July 3, 1917.

(a) Moist bagasse is tightly baled and the bales are allowed to dry and the bagasse then made into briquettes, the adhesive material contained in the bagasse itself acting as binding agent. (b) Bagasse

is prepared for combustion in boiler furnaces, etc., by mixing it with dry vegetable material, e.g., dry cane leaves cut into pieces.—J. H. L.

Sugars [and cattle food]; Process of producing — [from spent grains]. R. L. Utman, Baltimore county, Md. U.S. Pat. 1,259,568, Mar. 19, 1918. Date of appl., Sept. 28, 1916.

SUGARS and stock food are produced from waste materials such as brewers' or distillers' spent grains, by heating with dilute mineral acid, e.g., at 115°–120° C., to saccharify the carbohydrates present. The liquid, containing the sugars, may be neutralised after separation from the solid matter, and the latter, still containing the unaltered proteins, may be obtained free from acid and other deleterious substances and suitable for cattle food.—J. H. L.

Process of manufacturing vegetable gluc [from starch]. U.S. Pat. 1,257,307. *See* XV.

XVIII.—FERMENTATION INDUSTRIES.

Starch [in barley]; Determination of —. R. Kutzcha. *Woch. Brau.*, 1917, 34, 277–281, 290–291, 294–295, 304–306, 313–316, 323–325, 332–334, 339–341, 349–352, 359–360, 368, 375, 381–384, 391–392, 398–399, 406–408.

The author gives an historical summary of the researches on the determination of starch in barley, and recommends Lintner's polarimetric method (this J., 1912, 653). There is no constant relation between the starch-content of barley and the percentage yield of extract from the corresponding malt (both referred to dry substance); the results obtained by different investigators indicate that the amount by which the latter exceeds the former may vary considerably, average values ranging from 14.8 to 17.5 having been suggested (cp. Lintner, this J., 1911, 1080). The sum of the starch-content and the protein-content of barley is not constant, but may range between 70 and 74% for barleys of the same season. For the valuation of brewing barleys the starch-content is as useful as the extract-content (cp. Lintner, *ibid.*).—J. H. L.

Sorghum or millet [as malt adjunct]. J. Raux. *Brasserie et Malterie*, 1918, 7, 372–375.

BREWERS in France have recently been offered a new malt adjunct, viz., doura or millet, the seeds of *Sorghum vulgare*. It is used in distilleries and yields very pure spirit of pleasant flavour. It is sold in the form of whole grains, sometimes under-corticated, and also as flour. Its range of composition is as follows:—Moisture, 12–15%; starch, 62–66%; extract, 64–70%; fatty matter, 3–5%; total proteins, 10–13%. The yield of extract is about 8–10% lower than that from maize and 10–15% lower than that from rice; it is less than might be expected from the starch-content because the fatty matters present, as in the case of raw maize, impede conversion of the starch to some extent. The removal of the fatty matters would enhance the value of the material not only on this account, but also because they render it liable to become rancid. Millet appears to be well suited for brewing purposes provided it is in good condition, but it is subject to rapid deterioration when abnormally moist. Like maize and rice, it requires cooking to gelatinise the starch. Its use has sometimes given rise to difficulty in the filtration of the wort, but this is chiefly because it has been very finely ground. This trouble may be avoided by cooking under pressure, for in this case the grain need only be coarsely crushed.—J. H. L.

Alcoholic fermentation; Influence of variations of barometric pressure on the course of —.

A. Rippel. *Centralbl. Bakt.*, 1917, II., 47, 225—229.

In the fermentation of nutrient liquids by yeast it was observed that when fermentation was very slow, extending over 1—2 weeks, the rate of evolution of carbon dioxide, as measured by the loss in weight of the flasks containing the cultures, fluctuated from day to day. The fluctuations showed a certain correspondence with the variations of barometric pressure, low pressures favouring the evolution of gas, and *vice versa*.—J. H. L.

Fermentation; Influence of air pressure on —.

H. Zikes. *Allg. Z. Bierbrau. u. Malzfabr.*, 1917, 38, 229. *Woch. Brau.*, 1917, 34, 410.

BEER wort was fermented completely in flasks, some of which were closed by means of a sulphuric acid trap and others only with a plug of cotton wool. It was found that in the former case the wort attenuated more completely than in the latter case, though the evolution of gas was more rapid in the flasks closed with cotton wool. The more complete attenuation is attributed to exclusion of air, in consequence of which the yeast is compelled to obtain oxygen by increased decomposition of sugar. The author noted also fluctuations in the amount of gas evolved from day to day, as observed by Rippel (see preceding abstract), especially in the flasks closed only with cotton wool.—J. H. L.

Enzyme formation. H. Euler. *Biochem. Zeits.*, 1918, 85, 406—417.

ATTENTION is called to the fact that the formation of an enzyme (invertase) in developing yeast is not necessarily parallel with the rate of growth. A series of experiments was carried out with culture media containing, in addition to sucrose and necessary inorganic salts, the following substances as sources of nitrogen: glycine, glycine *plus* cystine, glycine *plus* tyrosine, asparagine, alanine, yeast water. There was no marked difference in the rate of growth with different amino-acids, but it was less than in the presence of yeast water. In yeast water the rate of formation of invertase was greater than in the presence of pure amino-acids, but here again there was no marked difference in the action of the individual acids.—S. B. S.

Molasses; Alcohol from waste — in the Philippine Islands. H. C. Brill and L. W. Thurlow. *Philippine J. Sci.*, 1917, 12, A, 267—292.

THE quantity of waste molasses produced in the Philippines in 1915 was probably about 30 million kilos. A typical sample contained 1.33% of potash, 0.38% of phosphorus, and 0.21% of nitrogen. The proportions of potash and nitrogen are low compared with those in Hawaiian molasses, because in many cases no fertilisers are applied to sugar lands in the Philippines and no attempt is made to return the fertiliser constituents in the ash of the bagasse and in the molasses to the soil. Before many years, however, fertilisers will have to be employed to maintain the yield of cane, and the authors consider that the most profitable method of disposing of the waste molasses is to produce alcohol and utilise the valuable constituents of the vinasses for fertilising. This is already being done to some extent, but the methods employed are very crude and the yield of alcohol is therefore low. The experiments described, made with a strongly-fermenting top-fermentation yeast isolated from nipa juice (cp. Pratt and others, this J., 1914, 656), indicate the lines on which improvements may be realised. Wherever practicable without excessive expense, the diluted molasses before inoculation should be

sterilised, e.g., by heating at 70° C., but where this is impossible only good water must be used for diluting. The diluted molasses should have a density of about 16.5° Brix (sp. gr. 1.0678), and should be treated with 2 grms. of sulphuric acid and at least 0.4 gm. of ammonium sulphate per litre. Ammonium fluoride has no greater stimulating action on fermentation than the sulphate. Sea water has a deleterious influence and reduces the yield of alcohol. Addition of rice polishings does not appear to improve the fermentation, but tends to increase the production of acids. The yeast employed should be free from infection; it may be cultivated from a pure culture in diluted molasses, 1 part of the fermenting liquid being seeded into 100—150 parts of unfermented solution. By beginning with a 10% solution of molasses and making each successive solution slightly more concentrated until a density of 16.5° Brix is attained, the ability of the yeast to ferment in more highly concentrated solutions is strengthened. The temperature of the fermenting liquid should be maintained between 28° and 30° C. by artificial cooling. By operating in this way the authors obtained yields of about 90% of the theoretical quantity of alcohol.

—J. H. L.

Spirit; Revision of the [Dutch] tables for the strength of —. N. Schoorl and A. Regenbogen. *Proc. K. Akad. Wetensch. Amsterdam*, 1918, 20, 831—837. *Pharm. Weekblad*, 1918, 55, 390—403.

THE authors have redetermined the densities of mixtures of ethyl alcohol and water at 15° C. Alcohol prepared from "supra-grain spirit" and from "prime grain (3) and molasses (3) mixed," when distilled over lime, shaken with freshly precipitated silver oxide, and finally distilled over metallic calcium gave concordant values for sp. gr. at 15°/4° C. = 0.79360. The densities of mixtures of this alcohol with water differ very appreciably in certain cases from those recorded by von Baumhauer (1860), on which the present Dutch official tables are based, but are in very close agreement with the values obtained by Osborne and MacKelvey (this J., 1913, 303), on which are based the tables issued by the U.S. Bureau of Standards. These tables are recommended by the authors as affording the most accurate compilation of the densities of mixtures of ethyl alcohol and water.—H. M. D.

Wood alcohol poisoning. A. O. Gettler and A. V. St. George. *Amer. J. Pharm.*, 1918, 90, 280—284.

DETAILS are given of six fatal cases of poisoning by whiskey adulterated with methyl alcohol. The presence of methyl alcohol was detected in the distillates from portions of the brains, by oxidising the liquid and applying the tests for formaldehyde. In view of the danger of direct introduction or inhalation of methyl alcohol into the body, it is suggested that its sale for domestic purposes should be prohibited, and denatured ethyl alcohol used in its place.—C. Germes [lactic bacteria]; Process for compounding — with an enveloping protective medium. I. F. Harlds, Bronxville, and F. W. R. Eschmann, Assignors to The Arlington Chemical Co., Yonkers, N.Y. U.S. Pat. 1,260,899, Mar. 26, 1918. Date of appl., Dec. 10, 1914.

GERMS, such as lactic bacteria, are prepared in a state of dormant vitality by enveloping them in a medium of a fatty composition. The germs are developed as a culture in a matrix fluid, the culture is filtered through a layer of inert material, the residue on the filter is dried and pulverised, the fatty enveloping medium is melted, and the pulverised residue incorporated therein. The enveloping medium should have a melting point below the temperature of the human body; It should be insoluble in water, and capable of protecting the germs against the action of air, moisture, and the gastric juice and body fluids.—J. F. B.

Rectification of fermented musts, methyl alcohol, and other liquids; Process and apparatus for —. E. Barbet et Fils et Cie., Paris. Eng. Pat. 14,041, June 10, 1914. Under Int. Conv., June 10, 1913.

XIXA.—FOODS.

Wheat or its milled or baked products; Determination of the residue indigestible in vitro by pancreatin acting on —. L. Devilliers. Comptes rend., 1918, 166, 700—702.

FIVE grms. of the product is digested with 0.025 gm. of Defresne pancreatin, 1 gm. of sodium borate, and 0.30 gm. of crystallised calcium chloride in 100 c.c. of water at 55° C., with thorough agitation, for three hours. The temperature is then slowly raised to 70° C. and more rapidly to 120° C. in an autoclave. The liquid is allowed to cool to 55° C., a further 0.025 gm. of pancreatin is added, and the digestion continued until the whole of the starch has disappeared. To the liquid hydrochloric acid is added until its acidity is equivalent to 0.175% of the acid, and the digestion is continued at 35°—40° C. for one hour, when the residue is filtered off, washed, dried, and weighed. Results are given for a number of samples of wheat, bran, flour, and bread made from the latter.—W. G.

Bread; Digestibility of —. III. Erythrodestrin in starch hydrolysis. J. C. Blake. J. Amer. Chem. Soc., 1918, 40, 623—636.

THE author has previously shown that the digestion of erythrodestrin is a unimolecular reaction, and might serve, therefore, in determinations of amylolytic activity. With the aim of devising a method of preparation of pure erythrodestrin for such purposes, the degradation of starch by heating at 85° C. after moistening with dilute hydrochloric acid and by boiling with dilute hydrochloric acid has been studied. The course of the decomposition was followed by measuring the colorations produced by iodine water, in a Duboseq colorimeter, a full account of the method being given. It appears that erythrodestrin is the final polysaccharide produced by the "roasting" process if the acid used to moisten the starch is sufficiently dilute. (See further J. Chem. Soc., 1918, i., 254.)—J. C. W.

Milk; Artificial colouring matter in —. H. E. Cox. Analyst, 1918, 43, 166—167.

MILK coloured with methyl orange loses its colour within 24 to 48 hrs., but annatto and turmeric give a relatively more permanent colour to the milk, fading only taking place after 6 to 14 days, or longer in the case of annatto. The presence of formalin retards the reduction of methyl orange, but accelerates the decolorisation of the vegetable dyes.—W. P. S.

Desiccated skim milk; Comparison of the proximate and mineral composition of — with that of normal cows' milk. E. P. Harding and H. Ringstrom. J. Ind. Eng. Chem., 1918, 10, 295—297.

THE proximate composition of commercial samples of desiccated skim milk shows but little variation except in the proportion of moisture, which ranges from 2 to 9% or more. The amount of fat rarely exceeds 2%. A typical American sample contained: Ash, 7.89; fat, 1.42; proteins, 32.86; moisture, 5.60; lactose 48.49; and acidity, 1.58%. Calculated on the basis of milk containing 9% of solids-not-fat, the mineral constituents corresponded closely with those of normal milk, except that the calcium oxide, magnesium oxide, and phosphoric anhydride were higher, possibly owing to the addition of phosphate as an emulsifying agent. Two other samples of different origin gave similar results, whilst in the case of a fourth, the colour, emulsifying power, high protein, low lactose, and high content of calcium and phosphorus indicated that the sample was not a genuine desiccated skim milk powder.

—C. A. M.

Gossypol, the toxic principle of cotton seed. F. E. Carruth. J. Amer. Chem. Soc., 1918, 40, 647—663.

Gossypol (see this J., 1917, 1285) is present in glands in all but the woody tissues of the cotton plant. The very sparingly soluble aniline salt, of the average composition, $2C_{30}H_{50}O_{10} \cdot 5C_6H_5NH_2$, may be used for the separation and determination of gossypol. A more yellow substance, "B" gossypol, is formed by heating at 186°—190° C., a white product, "C" gossypol, by fusion with alkalis, and another yellow compound, "D" gossypol, by cooking the cotton seed for oil. All four substances give blood-red solutions in concentrated sulphuric acid and fine blue colorations when their alkaline solutions are exposed to the air. By suitably conducted cold pressing the oil cells of cotton seed may be emptied without the oil dissolving the contents of the resin glands, and no gossypol then enters the cotton-seed oil, but in the usual cold pressing processes the seed is heated to a considerable extent and the glands ruptured, so that commercial "cold pressed" oil contains about 1.5% of gossypol, that is about three-fourths of the whole. In the "hot pressing" process, the gossypol is exposed to oxidising influences and changes largely into the less toxic "D" gossypol, most of which remains in the cake. Consequently, a "hot pressed" oil should lose less on refining with alkali than a "cold pressed" oil from the same seed. (See further J. Chem. Soc., 1918, i., 236.)—J. C. W.

Yeast; Preservation of moist —. W. Völtz. Woch. Brau., 1917, 34, 414.

LACTIC acidification affords a means of preserving moist yeast for feeding purposes in cases where drying is impracticable, though the latter method is to be preferred. Fresh yeast treated with 0.5—1% of sugar, e.g., in the form of molasses or pulped beets, may be mixed with chopped straw and inoculated with a pure culture of lactic bacteria. If stored in trenches impermeable by water, the yeast

will remain for a long time in good condition. Lactic acidification may also be applied to the preservation of other feeding-stuffs, *e.g.*, insufficiently dried green fodder, and products such as distillery vinasses. The addition of 0.5–1% of sugar is necessary to enable the lactic bacteria to develop.

—J. H. L.

Carbonating; Studies in —. II. *Carbonating of distilled water*. II. E. Patten and G. H. Mains. J. Ind. Eng. Chem., 1918, 10, 279–288.

IN experiments to test the rate of evolution of carbon dioxide from aqueous solutions bottled under pressure, a quart bottle was charged with 770 c.c. of distilled water, and, after cooling to 0° C., the liquid was impregnated with carbon dioxide by means of an apparatus in which the gas was introduced from a gas cylinder while the contents of the bottle were agitated by a rotating stirrer (J. Ind. Eng. Chem., 1917, 9, 787). The gas layer above the liquid was withdrawn and analysed and the time required for the initial pressure to be recorded again on the gauge was noted. This process was repeated several times, simultaneous readings of the time and pressure being recorded, until practically all the gas obtainable at 0° C. at atmospheric pressure had been removed. The bottle was then removed from the ice, further portions of gas withdrawn at the ordinary temperature, and it was finally placed in the steam bath, and the remainder of the gas expelled by boiling. The "pressure recovery" curves, constructed from these data, showed a striking regularity except in the case of the first curve corresponding with the first opening of the bottle, when an excessive quantity of gas was withdrawn. This was contrary to expectation, since a sudden rise of curve and rather sharp decrease of pressure were anticipated. In practice the saturation of aerated liquids is incomplete owing to the pressure of foreign gases (air), which reduce the partial pressure of the carbon dioxide. The effective pressure is that of the partial pressure of the carbon dioxide and not the total pressure of the gaseous layer as indicated on the pressure gauge. Complete equilibrium between the gas in the gaseous layer and in the liquid was not attained at the end of 19 hours, after the first opening of the bottle, but was practically complete after 40 hours. The fact that the length of time a bottle of aerated water is allowed to stand before opening increases the stability of the supersaturated solution after opening of the bottle, may be attributed to the gradual solution of gas bubbles retained by the walls of the bottle. The foregoing results also explain why a badly carbonated product containing a large proportion of air, or one which has stood for an insufficient length of time, may show a high initial pressure in the gaseous layer without a correspondingly great quantity of gas dissolved in the liquid. It also explains why the practice of removing the foreign gases by "sniffing" gives a better product. The time of carbonating may be shortened and the degree of impregnation increased by increasing the speed at which the liquid is stirred during the introduction of the gas.—C. A. M.

Estimation of fat in commercial egg yolks. Lamb and Harvey. See XV.

Fruits and vegetables; Processes and apparatus for drying wet or watery materials, especially —. J. R. van Musschenbroek, The Hague, Holland. Eng. Pat. 114,442, Jan. 2, 1917. (Appl. No. 105 of 1917.)

Hot air is supplied to the drying chamber through a number of passages which are subdivided so that separate channels are formed, each leading to a

separate rectangular area beneath a perforated tray containing the material to be dried. Means are provided for conducting the spent air to a regenerating chamber, and steam pipes are fitted between the layers of trays for maintaining the temperature of the air. Continuously moving tissues or cloths of hygroscopic material are also passed through the chamber to control the humidity of the air, and then through a separate drying chamber.—W. P. S.

Vegetables; Method of preparing evaporated —. *Method of preparing evaporated fruit. Method of preparing evaporated apples. Evaporated vegetable product. Evaporated apples. Evaporated fruits*. R. W. King, The Dalles, Assignor to Pacific Evaporator Co., Portland, Oreg. U.S. Pats. (A) 1,259,631, (B) 1,259,632, (C) 1,259,633, (D) 1,259,634, (E) 1,259,635, (F) 1,259,636, (G) 1,259,637, Mar. 19, 1918. Dates of appl., (A) to (D) June 27, 1916, and (E) to (G) June 29, 1917.

(A) VEGETABLES are treated with sodium chloride solution, steamed at a temperature at which the cells are not burst, and then dried in a current of air below 156° F. (69° C.). (B) Vegetables are subjected to a current of air at 125°–156° F. (52°–69° C.). (C) Fruit is treated with a bleaching agent and steam and dried at a temperature which will not disrupt the cells. (D) Apples are sliced, treated with 3% sodium chloride solution and a bleaching agent, and then dried below 156° F. (69° C.). (E) A steamed uncooked vegetable product which has been treated with sodium chloride solution and dried. (F) Apples which have been treated with sodium chloride and a bleaching agent and then evaporated. (G) An uncooked fruit product of the *Prunus* family which has been evaporated after treatment with a "fuming agent" and steam.—W. P. S.

Butter; Method of making composition —. *Artificial butter*. S. M. Dick, Assignor to F. E. Mick, Minneapolis, Minn. U.S. Pats. 1,258,996 and 1,258,997, Mar. 12, 1918. Dates of appl., Jan. 8 and Mar. 15, 1917.

CREAM is separated from milk, the separated milk is condensed, mixed with the cream, and the mixture sprayed into heated air so as to produce a mass of a buttery consistence.—W. P. S.

Meats; Process for curing —. *Pickling liquor and process of making the same*. G. F. Doran, Omaha, Nebr. U.S. Pats. (A) 1,259,376 and (B) 1,259,377, Mar. 12, 1918. Dates of appl., Dec. 13, 1915, and Nov. 28, 1916.

(A) MEAT is treated with a pickling liquid containing small amounts of soluble nitrites in addition to sodium chloride and other salts. (B) Old or used pickling liquid containing nitrites is purified and sterilised, suitable amounts of curing agents being added to restore it to the desired strength.

XIXe.—WATER PURIFICATION; SANITATION.

Bactericidal properties conferred on the blood by the intravenous injection of diaminoacridine sulphate. C. H. Browning and R. Galbransen. Proc. Roy. Soc., 1918, 90, B, 136–144.

DIAMINOACRIDINE sulphate when injected into rabbits renders their sera bactericidal to *Staphylococcus aureus* and *B. coli*. (See also J. Chem. Soc., 1918, i., 282.)—S. B. S.

Arsenic; Determination of — in insecticides by means of potassium iodate. G. S. Jamieson. J. Ind. Eng. Chem., 1918, 10, 290—292.

For the determination of arsenious oxide in Paris green or other arsenite, 0.15 to 0.4 gm. of the sample is treated with 30 c.c. of hydrochloric acid (sp. gr. 1.19), 20 c.c. of water, and 6 c.c. of chloroform, and the liquid titrated with standard potassium iodate solution (3.241 grms. per litre; 1 c.c.=0.003 gm. As₂O₃), in a glass-stoppered bottle. The reagent is added rapidly at first, until the iodine liberated has largely disappeared from the solution. The stopper is then inserted and the bottle thoroughly shaken, and the titration slowly completed, with vigorous shaking after each addition, until the iodine colour of the chloroform has disappeared, and does not appear again after standing for five minutes. It is essential that the acidity of the solution at the end of the titration should not be less than 11%, to prevent hydrolysis of the iodine monochloride formed, nor more than 20%, or the reaction will take place too slowly. For the determination of total arsenic in an insecticide the official (American) distillation process is used, the arsenic being distilled as arsenious chloride by means of empyreous chloride and strong hydrochloric acid, and received in Erlenmeyer flasks chilled with ice. An aliquot portion of the distillate is then titrated as described above.—C. A. M.

Softening and purification of water; Apparatus for the —. J. J. Lassen and V. F. Hjort, London. Eng. Pat. 114,485, Apr. 11, 1917. (Appl. No. 5982 of 1917.)

The process may be conveniently carried out in an old Lancashire boiler shell, upon the top of which are mounted the water and reagent tanks. After receiving the reagent the water passes to the flues of the boiler, the ends of which are blocked in order to make them suitable for settling tanks. From the top of the flues, pipes lead to the main shell of the boiler, which has a filtering material compartment at one end through which the water passes in an upward direction and thence to a reservoir. When it is desired to flush out the flues, their contents are run into a tank below the boiler. The exit pipe from this tank has a floating arm, which enables the water to be decanted from the surface and raised by a pump to the supply tank on the top of the boiler to be re-treated.—J. H. J.

Zinc compound [for treating boiler feed water]. F. O. Paige, Assignor to Paige and Jones Chemical Co., Inc., New York. U.S. Pat. 1,260,987, Mar. 26, 1918. Date of appl., July 31, 1917.

The material is composed of zinc dust, vegetable acid, alkali salts, and carbohydrates.—W. E. F. P.

Drying and decolorising night soil, slaughter house refuse, and other analogous materials; Apparatus for —. J. W. Stamp, Melbourne, Australia. Eng. Pat. 114,700, May 21, 1917. (Appl. No. 7275 of 1917.)

A closed rotating cylinder supported horizontally on hollow trunnions is enclosed in a casing through which gases from a furnace are passed. The material to be dried is fed into a hopper fitted with a splash shield and discharging into a valve-controlled pipe leading into one of the hollow trunnions and thence into the dryer. Vapour is withdrawn

through the other trunnion and thence through a condenser, by means of a vacuum pump beyond the condenser. The dried material is discharged through a door in the cylinder and a corresponding discharge opening on the lower side of the casing. Material to be dried may be charged directly into the cylinder through the discharge door, and the cylinder may be provided with Galloway tubes.

—W. E. F.

Garbage disposal; Method of —. E. C. Wallace, West Roxburg, and S. C. Prescott, Brookline, Assignors to The Bio-Chemic Fertilizer Co., Boston, Mass. U.S. Pat. 1,260,103, Mar. 19, 1918. Date of appl., July 5, 1917.

COMMUNICATED garbage is mixed with a dry bulky material in sufficient quantity to produce a mass containing spaces free from liquid and filled with air. The mass is inoculated with bacteria and kept under optimum conditions for bacterial growth. As the intensity of the bacterial action slackens more garbage is added.—J. H. J.

Insecticides. W. H. Hyatt, Long Ditton, Surrey, and E. N. Fellowes, London. Eng. Pat. 114,602, Dec. 22, 1917. (Appl. No. 19,008 of 1917.)

THE insecticides consist of (1) a mixture of copper sulphate, 32 parts, neutral sodium sulphate, 36 parts, and ammonium carbonate, 24 parts, prepared by mixing together the powdered ingredients, or by evaporating to dryness a solution of the copper and sodium sulphates and adding the powdered carbonate, and (2) a mixture of copper sulphate, 32 parts, and ammonium carbonate, 36 parts, in powdered form.—J. H. J.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Ipecacuanha; Alkaloids of —. Part III. F. L. Pyman. Chem. Soc. Trans., 1918, 113, 222—234.

O-METHYLPSYCHOTRINE (this J., 1917, 1192), on reduction, gives a mixture of emetine and isocemetine. It was therefore to be expected that isocemetine, like emetine, would yield on oxidation methylpsychotrine and rubremetine, and this was proved to be the case. Thus emetine and isocemetine are proved to be stereoisomerides, but it has not so far been possible to establish an equilibrium between the two bases to form a racemic modification. Psychotrine gives cephaeline and isocephaeline on reduction, and methylpsychotrine gives emetine and isocemetine; it is now shown that isocemetine is the methyl ether of isocephaeline, and it has been prepared by the methylation of the latter. When methylated under suitable conditions, isocemetine gives a well crystallised N-methyl derivative; this is the O-methyl ether of N-methylisocephaeline previously obtained (this J., 1914, 764). Complete methylation of isocemetine yields a well crystallised N-methylisocemetine methiodide, which is accompanied by an amorphous salt, probably a mixture of two stereoisomeric methiodides. Both products give N-methylisocemetinemethine when converted into the corresponding methohydroxides and evaporated in a vacuum. By the complete methylation of emetine a stereoisomeric β -N-methylemetine methiodide, m. pt. 262° C. (corr.) and $[\alpha]_D = +68^\circ$, has now been isolated in addition to the original α -methiodide, m. pt. 225°—226° C. (corr.) and $[\alpha]_D = -10^\circ$, both yielding the same methine; these two isomerides are due to the asymmetry of the tertiary N atom common to two-ring complexes. Considerable differences in the physiological action of emetine and isocemetine have been observed; the hydro-

chloride of isometine is less than half as toxic as that of emetine. When administered in cases of amebic dysentery emetine is nauseating but effective, whereas isometine is well tolerated but ineffective towards the amebæ.—J. F. B.

Atropine sulphate; Melting point of —. H. D. Richmond. Analyst, 1918, 43, 168.

ACCORDING to the B.P., atropine sulphate melts at 189°–190° C., whilst the U.S.P. gives the m. pt. as 188°–191° C., or 181°–183° C. when the substance is dry and free from hyoscyamine. These statements are erroneous, since the true m. pt. of atropine sulphate is 194° C. In determining the m. pt. the temperature of the bath should at first be 25° C. below the m. pt. and then be raised gradually; if the temperature of the bath is near the m. pt. when the capillary is introduced, traces of water in the sulphate are expelled rapidly, but at the same time cause the salt to sinter together and appear to melt.—W. P. S.

Homatropine and the Vitali test. H. D. Richmond. Analyst, 1918, 43, 167–168.

THE Vitali test cannot be used to distinguish homatropine sulphate from atropine, hyoscyamine, or hyosine, since the sulphuric acid of the sulphate so intensifies the action of the nitric acid that a violet coloration is produced. If, however, the test is applied to the homatropine itself, after separation from the sulphate, a violet coloration is not obtained.—W. P. S.

Digitalis; Effect of cleaning on the inorganic constituents of —. C. H. Rogers and E. H. Newcomb. Amer. J. Pharm., 1918, 90, 239–252.

THE normal ash of digitalis amounts to from 8–10%, but commercial samples may yield over 25%. The U.S. Pharmacopœia fixes the limit at 15%. By sifting the dried digitalis through a 14-mesh sieve the adhering foreign matter may be removed, leaving a residue with the normal amount of ash. For example, a composite sample of the original crop yielded 11.36 to 11.59% of ash, and, when screened, was separated into two portions yielding respectively 9.28% and 26.24% of ash. By further treatment the latter portion (about 20%) was separated into fine siftings yielding over 56% of ash, and coarser portions yielding about 9 to 10%, the loss of actual digitalis being less than 31%. Only 4.35% of the ash of the screened digitalis was insoluble in hydrochloric acid. Manganese is a constant constituent of digitalis leaves, but varies in amount with the origin of the sample. Digitalis grown in Minnesota normally contains iron, calcium, magnesium, manganese, potassium, and sodium. The ash from the leaves of cultivated plants is usually higher than that of wild plants.

—C. A. M.

3,4-Dihydroxyphenanthrene (morphol) and 3,4-phenanthraquinone; Synthesis of —. G. Barger. Chem. Soc. Trans., 1918, 413, 218–221.

3-PHENANTHROL-4-ALDEHYDE (Chem. Soc. Trans., 1916, 109, 568) was converted into 3,4-dihydroxyphenanthrene (morphol) by Dakin's reaction. 1.11 grm. of the hydroxy-aldehyde was dissolved in 10 c.c. of pyridine, the air was displaced from the flask by a current of hydrogen, and 6.55 c.c. of 30.8% hydrogen peroxide was added; the addition of 0.45 c.c. of 12.5 N-potassium hydroxide solution then caused a considerable rise of temperature. After boiling for a few seconds, the liquid was cooled, acidified with hydrochloric acid, and the morphol extracted with ether. The yield of recrystallised morphol amounted to 80% of the theoretical. The substance was identified by its m. pt., 142°–143° C. by its

diacetate, m. pt. 159° C., and by conversion into its dimethyl ether. 3,4-Phenanthraquinone was prepared by oxidation of the diphenol in ethereal solution by dry silver oxide in presence of silver sulphate; it was obtained in brilliant red, short, pointed prisms with not very definite melting point, about 132°–133° C. on rapid heating; it did not yield Laubenheimer's reaction.—J. F. B.

Phenylethylbarbituric acid; Preparation of —. M. Rising and J. Stieglitz. J. Amer. Chem. Soc., 1918, 40, 723–730.

SOME practical notes are given on the synthesis of phenylethylbarbituric acid, which was introduced as a specific in epilepsy under the name "luminal," and is now officially termed "phenylbarbital" in America, as veronal is designated "barbital." Methyl phenylacetate obtained by saturating a solution of benzyl cyanide in 90% methyl alcohol with hydrogen chloride, and methyl oxalate obtained by saturating a solution of anhydrous oxalic acid in methyl alcohol with hydrogen chloride, are mixed together, treated with sodium wire and ether and a few drops of alcohol and the resulting sodium compound is decomposed by dilute sulphuric acid, giving dimethyl oxallylphenylacetate, $\text{CH}_3\text{O}^-\text{CO}^-\text{CO}^-\text{CH}(\text{C}_6\text{H}_5)\text{CO}^-\text{CH}_3$. This is heated *in vacuo* when it loses carbon monoxide and gives methyl phenylmalonate $\text{C}_6\text{H}_5\text{CH}(\text{CO}^-\text{CH}_3)_2$, b.pt. 147°–159° C. under 10 mm. This ester is warmed with ethyl iodide and a solution of sodium in methyl alcohol, and the methyl phenylethylmalonate so formed is heated with urea and a solution of sodium in methyl alcohol, in a sealed tube at 105°–108° C. for 6 hours.—J. C. W.

Acetylsalicylic acid; Examination of American-made —. P. N. Leech. J. Ind. Eng. Chem., 1918, 10, 288–290.

PURIFIED acetylsalicylic acid melted at 131.5°–132.5° C. (corr.), whilst 14 samples of American origin melted between 128° and 133° C. It is suggested that this latter range of m. pts. is more correct than those of the British Pharmacopœia (133°–135° C.), the German Pharmacopœia ("about 135° C."), and the French Pharmacopœia (135° C.). With one exception all the commercial samples examined contained less than 0.1% of free salicylic acid, as determined colorimetrically, and it is proposed that this limit should be adopted as a standard.—C. A. M.

Crotonisation of acetaldehyde; formation of butanol and hexanol from ethyl alcohol. P. Sabatier and G. Gandion. Comptes rend., 1918, 166, 632–635.

THE conversion of ethyl alcohol into butanol and hexanol is effected in three stages, viz., reduction to acetaldehyde by passing the alcohol vapour over reduced copper at 300° C.; dehydration of the aldehyde by passing its vapour over the oxides of thorium, titanium, or uranium, preferably the last-named, at 360° C.; hydrogenation of the products of crotonisation by passing their vapours with hydrogen over reduced nickel at 170°–180° C., butanol and hexanol with small amounts of higher isomerides being thereby obtained. Stages one and two may be carried out simultaneously by passing the ethyl alcohol vapour slowly over uranium oxide at 360° C. The best yield in stage two is obtained by starting with paraldehyde, and the products from this process are roughly fractionated, the fractions boiling at 90°–130° C. and 130°–220° C. being used for the third stage.—W. G.

Sulphite turpentine. Schorger. See V.

[Determination of] lead in commercial cream of tartar. Jones. See VII.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.**PATENT.**

Sensitised paper or like flexible material for use in obtaining X-ray photographs or radiograms; Preparation of —. G. W. K. and T. P. K. Crosland, Huddersfield. Eng. Pat. 114,933, June 4, 1917. (Appl. No. 7961 of 1917.)

Sensitised paper or other flexible material is coated on both sides with a preparation of Venetian red, chrome yellow, or other material opaque to light and which can be easily removed by washing.

—B. V. S.

XXII.—EXPLOSIVES; MATCHES.**PATENT.**

Manufacture of ammonium perchlorate. Eng. Pat. 110,544. See VII.

XXIII.—ANALYSIS.

Colorimetric determinations; Influence of suspended matter on —. T. Van der Linden. Archief Suikerind. Ned.-Indië, 1917, 24, 1871—1874. Intern. Sugar J., 1918, 20, 195.

In experiments on the effect of clarifying sugar syrup by boiling and settling, it was found that although there had been an appreciable increase in the purity of the product, the reading in a colorimeter indicated that the syrup was much darker after treatment than before. Further examination showed that the boiled syrup had about the same colour intensity as the unboiled product, the anomalous results being due to the fact that the readings were taken with samples that had not been filtered and contained a small amount of suspended matter. In order to obtain trustworthy results in colour determinations, it is necessary to operate only with solutions that are quite clear and bright.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.**APPLICATIONS.**

Balcombe. Making extracts of soluble matter. 8571. May 23.

Barbet et Fils et Cie. Tubular evaporating, condensing, and cooling apparatus. 8821. May 25. (Fr., June 21, 1917.)

Barbet et Fils et Cie. Apparatus for continuous rectification of liquid air. 8954. May 30. (Fr., Oct. 9, 1917.)

Batchelor. Furnaces. 8285. May 17.

Böckman. Furnaces, etc. 8271. May 17. (Norway, Nov. 27, 1917.)

Calvert. Apparatus for catalytic reactions. 7997. May 13.

Carrier Engineering Corporation, and Carrier. Drying, conditioning, and regulating moisture content of hygroscopic materials. 8461. May 21.

Crowcroft and Morris. Furnaces. 8137. May 15.

Fennell. Rotary furnaces or kilns. 9022. May 31.

Hersey, and Kirkham, Hulett, and Chandler. Apparatus for effecting intimate contact between liquids and gases. 9005. May 31.

Johnston. Dehydrating or drying machine for extracting moisture from vegetable, animal, or mineral matter. 8266. May 17.

Kuehrich. Furnaces. 8611. May 24.

Moreton. Mixing, stirring, or agitating apparatus. 8908. May 30.

Seames. Apparatus for maintaining vacuum in steam-condensers, evaporating-plant, etc. 8253. May 16.

Soc. Gallot et Cie. 8529. See XI.

Turner. Process for fractional or destructive distillation of liquids. 8011. May 13.

Vacuum Oil Co. Fractional condensing heat-exchanger. 8158. May 21.

Wilson. Filter presses. 8482. May 22.

Wise. Distilling. 8621. May 24.

COMPLETE SPECIFICATIONS ACCEPTED.

1277 (1917). Marschall. Manufacture of thermoclements having copper sulphide as the positive constituent. (103,671.) June 5.

6339 (1917). Bowrey. Apparatus for fractional distillation. (115,504.) May 23.

7068 and 13,925 (1917). West. Continuous or series kilns. (115,696.) May 29.

7259 (1917). Soc. de Stearinerie et Savonnerie de Lyon, and Berthon. Production of catalysts for reduction or hydrogenation, and apparatus therefor. (107,001.) June 5.

7612 (1917). Thompson (Elmore). Centrifugal drying-machines. (115,909.) June 5.
 8219 (1917). Cleworth. Wet filters, water coolers, etc. (115,521.) May 23.
 8295 (1917). Lane. Preparation of catalytic material employed for promoting synthetic chemical reactions. (115,924.) June 5.
 10,150 (1917). Furse and Neill. Crushing and pulverising machines. (115,542.) May 23.
 10,860 (1917). Heenan and Froude, and Walker. Apparatus for treating and cooling air and gas. (115,546.) May 23.
 1035 (1918). Meihuizen. Drying apparatus. (114,620.) May 29.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Abrahams and Parker. Apparatus for generation, from incandescent carbonaceous material, of fuel gas for internal combustion engines. 8296. May 17.
 Anderson. Apparatus for producing oil fuel. 8499. May 21.
 Davies. Preparation of fuel briquettes and utilising them in carbonisation, combustion, gasification, etc. 8369. May 31.
 Davis. Treatment of flue gases. 8440. May 31.
 Freer and Schauermaun. Liquid fuel. 8079. May 14.
 Grange Iron Co., and Hoyle. Apparatus for washing coal, etc., and separating it from impurities. 8539. May 22.
 Hackford, Smith, and Pearson & Son. Treatment of coal, coal products, etc. 8476. May 21.
 Helps. Gas manufacture. 8569. May 23.
 Lynn and Rambush. Gas producers. 8258. May 17.
 Marks (Soc. Franco-Belge de Four à Coke). Horizontal coke-ovens. 8583. May 23.
 Nelson. Desulphurising hydrocarbon oils. 8899. May 29.
 O'Donnell. Powdered fuel, and process of treating same. 8310. May 17.
 Perry. Apparatus for distilling carbonaceous material. 9010. May 31.
 Reed. Extraction of hydrocarbon products from shales and coals. 8330. May 17. (U.S., Sep. 28, 1917.)
 Rew. Carbonisation of coal, etc. 8438. May 21.
 Turner. 8011. *See* I.
 Wade (China Sugar Refining Co., and others). 9037. *See* XVII.
 Walster and Walster. Generating coal-gas in retorts. 8479. May 22.
 Webb. Incendiary compositions. 8245. May 16.
 Whittaker. 8100. *See* III.

COMPLETE SPECIFICATIONS ACCEPTED.

13,749 and 13,800 (1916). Aktiebol. Ingeniörsfirma F. Egnell. *See* XXIII.
 1219 (1917). Heyl. Obtaining a distillate of shale free from sulphur. (115,452.) May 23.
 5081 (1917). Heyl. Obtaining a distillate from shale, free from sulphur. (115,867.) June 5.
 7813 (1917). Simmance. *See* XXIII.
 8525 (1917). Bates. Incandescence gas mandes, and method of making same. (115,720.) May 29.
 10,283 (1917). Toogood, and Dempster & Sons. Construction of vertical retorts. (115,738.) May 29.
 12,834 (1917). Goodall, Clayton & Co., and Settle. Manufacture of coal gas. (115,997.) June 5.
 12,855 (1917). Shannon. Liquid fuel. (114,411.) May 23.

13,485 (1917). Justice (Pirani). Obtaining motor fuels and light paraffin oils from shale, and benzene, toluene, and solvent naphtha from coal. (115,573.) May 23.

1114 (1918). Soc. d'Exploit. des Appareils Rateau. Apparatus for the production of water-gas. (112,942.) June 5.

2059 (1918). Pearson and Meredith. Manufactured fuel. (115,790.) May 29.

3455 (1918). Snowdon. Repair of coke ovens and the like. (116,059.) June 5.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Whittaker. Apparatus for distilling lower boiling constituents from oil, etc. 8400. May 21.

Wilton. Continuous dehydration and distillation of tar, etc. 8813. May 28.

COMPLETE SPECIFICATIONS ACCEPTED.

7485 (1917). Brotherton & Co., Porteous, and Whitelock. Apparatus for extracting naphthalene salts and similar substances from coal tar distillates. (115,906.) June 5.

13,485 (1917). Justice (Pirani). *See* III.

IV.—COLOURING MATTERS AND DYES.

APPLICATION.

Bauer. Colouring-materials. 8515. May 22.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Aktiebolaget Cellulosa. Production of soda cellulose, particularly wood cellulose. 8750. May 27. (Sweden, June 1, 1917.)

Cross and Bevan. Treatment of fibrous cellulose for the production of hydrated derivatives. 8312. May 17.

Dents. Gasglühlicht A.-G. Method of loading silk. 8517. May 22. (Ger., May 22, 1917.)

Dents. Gasglühlicht A.-G. Production of artificial silk. 8518. May 22. (Ger., May 22, 1917.)

Dydynski. Retting. 8956. May 30.

Farbenfabr. vorm. F. Bayer und Co. Adhesive or agglutinating substances for cellulose derivatives. 8977. May 14. (Ger., Apr. 20, 1917.)

Hill. Wood fibre or artificial silk. 8616. May 24.

Hyndman. Treatment of tow of flax, etc. 8729. May 27.

Knight. Manufacture of paper, etc. 8665. May 24.

Lovell. Colloid-treated fabrics. 8527. May 22. (U.S., June 27, 1917.)

McKee. Process of obtaining alcohol from sulphite liquors. 8158. May 15.

Masters. 8917. *See* IX.

Morris. Applying powdered material to surface of fabrics. 8840. May 29.

Poulson. Rendering textile fabrics, etc., water-proof and fireproof. 9055. June 1.

Privett, and Thames Paper Co. Apparatus for drying paper, paper board, etc., during manufacture. 9026. May 31.

Radeliffe. Manufacture of acetylcellulose. 8216. May 16.

COMPLETE SPECIFICATIONS ACCEPTED.

9045 (1917). Galloway and Stratton. Utilising waste paper for remaking into white paper. (115,949.) June 5.

10,999 (1917). Cowan and Brown. Apparatus for treating paper pulp and other fibrous materials. (115,972.) June 5.

13,679 (1917). Stewart, Hall, and Beadie. Treatment of certain plants for paper-making. (116,005.) June 5.

18,952 (1917). Cowan and Brown. Apparatus for treating paper pulp and other fibrous material. (116,040.) June 5.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Barrett and Pennington. Manufacture of carbonic acid gas. 8072. May 14.
 Becquevort. Manufacture of metabisulphites, bisulphites, sulphites, etc. 8198. May 16.
 Bertoya. Reduction of oxides and other salts. 7989. May 13.
 Cloke and Cloke. Rendering arsenic contained in arsenic works, refining furnaces, residues, etc., recoverable by volatilisation. 8045. May 14.
 Cocksedge and Freeth. Removal of sodium sulphate from solution. 8986. May 31.
 Field, and Metals Extraction Corporation. Purification of zinc solutions. 8735. May 22.
 Field, Sulman, and Metals Extraction Corporation. Purification of zinc solutions. 8831 and 8832. May 28.
 Qulman. Production of sulphuric acid. 8322. May 17.
 Rivett. Production of ammonium nitrate. 8228. May 16.
 Rollason. Utilisation of atmospheric nitrogen in the manufacture of ammonia and other compounds. 8614. May 24.
 Sheard. Manufacture of sulphate of ammonia. 7972. May 13.
 Uthelm. Manufacture of acetic acid. 8025. May 13. (Norway, June 1, 1917.)
 Wilton. Manufacture of sulphate of ammonia. 8812. May 28.

COMPLETE SPECIFICATIONS ACCEPTED.

117 (1917). Levin. *See* XI.
 3399 (1917). Ore. Manufacture of ammonia or its salts. (115,449.) May 23.
 6379 (1917). Jones (Willing). Preparing water-soluble compounds of aluminium with organic acids. (115,463.) May 23.
 7014 (1917). Levin. Manufacture of pyrophosphoric acid and acid pyrophosphates. (115,693.) May 29.
 12,370 (1917). Steiger and Steiger. *See* IX.
 17,543 (1917). Steiger. *See* IX.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Dean, Gasch, and Kettel. Platinising pottery, earthenware, etc. 8903. May 13.
 Koizumi. Lacquer decoration on glass. 9090. May 31.
 McCauley. Conveyance of molten glass. 9030. May 31.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Cullis. Concrete, etc. 8243. May 16.
 Hartner. Manufacture of mortar-forming material from anhydrite. 8395. May 17. (Ger., July 18, 1917.)
 Kiddie. Machines for mixing concrete ingredients, etc. 8828. May 28.
 Masters. Waterproofing mixture for making Portland cement non-absorbent when kept in water. 8916. May 30.
 Masters. Waterproofing solution for timber, linen, flannelette, paper, etc. 8917. May 30.

COMPLETE SPECIFICATIONS ACCEPTED.

9249 (1917). Charlton. Manufacture of cementing materials. (115,946.) June 5.
 12,370 (1917). Steiger and Steiger. Shaft furnaces for burning cement, lime, etc. (109,266.) May 23.

17,543 (1917). Steiger. Kilns for burning cement, lime, or the like. (111,854.) May 23.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Adam and Stevenson. Removal of tin coating from tinned iron. 8063. May 21.
 Bertoya. 7989. *See* VII.
 Böckman. Reduction and smelting of ores. 8271 and 8272. May 17. (Norway, May 29 and June 29, 1917.)
 Burgan and Winder. Machine for testing hardness of metals. 9045. June 1.
 Carmichael (A.-G. f. Autogene Aluminium Schweissung). Autogenous welding of aluminium or its alloys. 8874. May 29.

I.—GENERAL ; PLANT ; MACHINERY.

Combustion of coal and design of furnaces. Krelsinger and others. See 11A.

PATENTS.

Vapour condensers and like apparatus; Tubulous —. W. L. Flinn, Elizabeth, N.J., U.S.A. Eng. Pat. 114,945, July 12, 1917. (Appl. No. 10,086 of 1917.)

EACH horizontal pipe section of a condenser or like coil is provided with a separate trough for the cooling liquid, the pipe and trough being spaced apart by a web having an opening for the passage of liquid. The trough has one upturned end to accommodate the corresponding end of the pipe, and this end is provided with lugs by means of which it may be supported in a frame. The trough supports the pipe at that end of the latter which is connected to the section next above, and the trough is supported by the pipe at the opposite end by means of a suitable bridge-piece spanning the trough and held against the pipe by inclined bolts carried by a collar surrounding the pipe. The bridge-piece is provided with an opening to maintain the desired liquid level, and to direct the liquid over the end of the pipe into the upturned end of the trough below. The apparatus is specially adapted for use with pipes having liquid-sealed joints as described in Eng. Pat. 113,907.—W. F. F.

Jacketed vats for heating and cooling liquids. A. G. Enock and Co., Ltd., and A. G. and E. C. Enock, London. Eng. Pat. 115,126, June 1, 1917. (Appl. No. 7867 of 1917.)

THE vat is constructed with an inner vessel and an outer casing, a coil or series of tubes being placed in the intermediate space adjacent to the inner vessel, and surrounded by insulating material held in position by the outer casing. A cooling or heating fluid is circulated through the coil or tubes. In the interior of the vat a swinging coil is mounted to agitate the contents, and a cooling or heating fluid is circulated through it.—J. H. P.

Oil and similar liquids; Apparatus for cleansing and filtering —. J. S. Highfield, London. Eng. Pat. 115,140, July 3, 1917. (Appl. No. 9497 of 1917.)

THE liquid to be treated is pumped into a vertical cylindrical vessel, through an inlet tube a short distance above the bottom, and passes upwards through a horizontal layer of powder, e.g., fullers' earth, supported between metal gauze on a perforated plate. Above is a clear space in which some settlement takes place. The upper part of the cylinder is occupied by a filter-press consisting of a series of horizontal wheels with perforated plates covered with filter-cloth between. The liquid enters the press by means of a central hollow shaft, passes through holes into alternate wheels, through the cloth both upwards and downwards into the other set of wheels, and, leaving these, passes upwards through a space between the circumference of the press and the sides of the apparatus, and out through a pipe at the top of the vessel. The lid of the apparatus can be screwed down in case it is necessary for the liquid to leave the apparatus under pressure.—L. A. C.

Heat-insulating compounds. N. Ito, Tokyo, Japan. Eng. Pat. 115,163, Aug. 8, 1917. (Appl. No. 11,419 of 1917.)

A HEAT-INSULATING compound, suitable for covering boilers, steam-pipes, etc., is made by adding 4 to 7

parts of sodium bicarbonate to 100 parts of a solution of calcium bicarbonate prepared from lime water and mixing this solution with 50 parts of kieselguhr, 20 parts of fibrous asbestos, 40 parts of magnesium carbonate, and 40 parts of anhydrous calcium sulphate.—A. B. S.

Separator; Centrifugal —. T. H. Parker, San Francisco, Cal. U.S. Pat. 1,262,384, Apr. 9, 1918. Date of appl., May 26, 1917.

A ROTARY distributor, 14, 19, is connected by radial webs to a shaft, 12, supported by an overhead bearing. The liquid to be separated is raised from the vessel, 20, by the rotation of the inclined ribs,

21, and discharged at the flared edge, 15, of the distributor into the annular shell, 17. This shell is open at the top and bottom, and is provided with lips, 18, 26, projecting inwards so as to confine a mass of heavy liquid within the shell to a level above the rim of the distributor. The lighter liquid is thereby prevented from passing below the rim, 15, and is discharged over the upper edge of the shell, while the heavier liquid is discharged over the lower edge. Separate discharge outlets are provided as shown.—W. F. F.

Drying apparatus; Powder —. F. L. Caskey, Buffalo, N.Y. U.S. Pat. 1,262,448, Apr. 9, 1918. Date of appl., Mar. 14, 1917.

A VERTICAL cylindrical drying chamber is provided with axial supply and discharge pipes at the top and bottom respectively, and is surrounded by a heating coil, the whole being enclosed in a casing. The pipes at their free ends carry discs, provided with annular channels on their outer faces which engage with corresponding ribs on other discs so as to close the pipes. The lower closure disc carries a short tube sliding within the discharge pipe, and having a side opening for discharge, and this disc may be moved axially by a hand-operated screwed rod so as to vary or close the discharge opening.—W. F. F.

Separating and dewatering device. F. W. Beardslee, Assignor to M. T. Beardslee, San Francisco, Cal. U.S. Pat. 1,262,738, Apr. 16, 1918. Date of appl., Sept. 25, 1916.

THE inflowing material is directed against the buckets of a floating turbine wheel in a container divided by baffles into inner and outer zones. The light material and liquid are withdrawn from the inner zone near the upper end of the container,

whilst the heavier material, which is projected outwards, sinks to a valved discharge outlet at the bottom. The discharge valve is connected with the turbine wheel, so that the consistency of the heavier material discharged is varied according to the height of the material in the tank.—J. H. P.

Thickening process; Continuous — A. L. Genter, Assignor to General Engineering Co., Salt Lake City, Utah. U.S. Pat. 1,263,226, Apr. 16, 1918. Date of appl., Sept. 12, 1917.

In a continuous filtering and thickening process, in which filtration is effected under pressure, the filter medium is cleansed automatically and continuously *in situ* by directing alternately, in any desired succession, the filter current against one side of the filter medium simultaneously with the release of pressure on the filtrate side, and a cleansing current against the opposite side of the filter simultaneously with the release of the filtration pressure.—J. H. P.

Gases; Process for the removal of — from gaseous mixtures. P. Beck, Cöln-Ehrenfeld. Ger. Pat. 302,092, Oct. 16, 1915.

THE gaseous mixture is passed through a cooled layer of lignite previously heated until no further evolution of gas takes place. It is an advantage to have the lignite in granular form or as briquettes, and not as a fine powder. The process may be applied to the removal of valuable or injurious gases from waste gases.—B. V. S.

Gaseous mixtures; Process for the separation of —. Ges. für Linde's Eismaschinen A.-G., Höllriegelskreuth, and F. Pollitzer, Munich. Ger. Pat. 302,674, Sept. 12, 1916. Addition to Ger. Pat. 301,941.

FOR the separation of a mixture of, *e.g.*, air, alcohol, and ether, the cooled gas is brought into intimate contact with a well-cooled mixture of alcohol and ether similar to that produced by condensation of the gas.—L. A. C.

Lubricant [from sulphite waste liquor]. Kirchbach'sche Werke, Coswig. Ger. Pat. 302,188, May 30, 1915.

THE composition consists of graphite, talc, or other minerals and sulphite waste liquor.—L. A. C.

Separating water, oil, or impurities from steam or air; Device for —. Device for separating oil, moisture, and impurities from exhaust steam or air. W. H. Taylor and C. Shaw, Sheffield. Eng. Pats. 115,103 and 115,104, May 3, 1917. (Appl. Nos. 6273 and 6274 of 1917.)

Condensers. C. J. Snow, Redwood City, Cal., U.S.A. Eng. Pat. 115,141, July 3, 1917. (Appl. No. 9564 of 1917.)

Classifiers. A. L. Blomfield, Denver, Colo., U.S.A. Eng. Pat. 115,184, Oct. 10, 1917. (Appl. No. 14,684 of 1917.)

Organic chemical reactions; Apparatus for performing —. A. M. Aylsworth, and Savings Investment and Trust Co., East Orange, N.J., U.S.A. Eng. Pat. 103,665, Jan. 17, 1917. (Appl. No. 884 of 1917.) Under Int. Conv., Jan. 24, 1916.

SEE U.S. Pat. 1,213,143 of 1917; this J., 1917, 382.

Filters. C. D. Burchenal, New York. Eng. Pat. 104,673, Nov. 15, 1916. (Appl. No. 16,372 of 1916.) Under Int. Conv., Mar. 10, 1916.

SEE U.S. Pat. 1,194,949 of 1916; this J., 1916, 1000.

Drying solid bodies containing liquid; Process and apparatus for —. J. W. A. Elling, Assignor to A./S. Myrens Verksted, Christiania, Norway. U.S. Pat. 1,263,392, Apr. 23, 1918. Date of appl., Mar. 20, 1917.

SEE Eng. Pat. 105,072 of 1917; this J., 1918, 280 A.

Evaporating apparatus. J. A. Reavell and W. G. Mann, London. U.S. Pat. 1,263,467, Apr. 23, 1918. Date of appl., Nov. 12, 1917.

SEE Eng. Pat. 110,921 of 1916; this J., 1917, 1262.

II.A.—FUEL; GAS; MINERAL OILS AND WAXES.

Combustion of coal and design of furnaces. H. Kreisinger, C. E. Augustine, and F. K. Orvitz. U.S. Bureau of Mines. Bull. 135. 144 pages.

PREVIOUS investigations (this J., 1917, 919) have shown that the reactions in the fuel bed of hand-fired furnaces are essentially those of the formation of producer gas. In the present experiments the combustion of these gases and the volume of combustion space required have been studied on a working scale. The furnace consisted of a Murphy stoker with a grate area of 25 sq. ft., built at the end of a horizontal tunnel, 40 ft. long and 3 × 3 ft. in section, which formed the combustion chamber. Arrangements were made for measuring temperatures and for taking samples of gas at intervals of 5 ft. along the combustion chamber. One hundred experiments were made on three types of bituminous coal (Pocahontas, Pittsburgh, and Illinois) at rates of combustion varying from 20 to 60 lb. per sq. ft. of grate area per hour. In general the results showed that the volume of combustion space necessary for complete combustion depends chiefly on the kind of coal, the rate of consumption of fuel, and the amount of excess air. On leaving the fuel bed the gases contain from 10 to 28% of combustible constituents, representing 40 to 60% of the heating power of the coal burned. Heat is developed by combustion of these constituents with the secondary air, at first rapidly and then with diminishing speed as the combustion space is traversed. Increased rate of firing leads to less complete combustion, while increase of combustion space and excess of oxygen favour its completion. The volume of combustion space required appears to be directly proportional to the product of the percentage of volatile matter and a factor of quality—volatile carbon divided by the available hydrogen. The difficulty of burning the volatile matter rises with increase of contained carbon. The gases travel along the combustion space in stratified layers, and, by delaying admixture, this retards combustion, so that the mode of introducing secondary air is important. Hydrocarbons are rapidly destroyed above the fuel bed, and only very small quantities are present in the gases after travelling 1 or 2 ft. On the other hand, soot persists for a long time in the atmosphere of rarefied oxygen, even when excess of air is present. Cooling surfaces such as boiler tubes do not cause the formation of soot, but merely collect it. The relation of various factors is shown graphically in a series of curves, and it is concluded that the requisite dimensions of furnaces for given conditions can be forecast from the data given.—H. J. H.

Coke and coke breeze; Mechanical stokers for —. B. Lepslen. J. Gasbeleuchtung., 1918, 61, 3–9.

COKE and even coke breeze can be used in hand-fired boiler furnaces where moderate rates of steaming are required, although the latter demands unusual attention from the fireman. Sprinkler mechanical stokers do not give a uniform distribution of breeze over the fuel bed. Breeze can be successfully burned on a so-called "Pluto" stoker. The breeze is fed from a hopper on to a series of inclined iron grates, resembling ladders with horizontal steps, down which the fuel slides until the clinker falls over the end. A slight reciprocating motion is imparted to the ladders, adjacent units always moving in opposite directions. The difficulty of ignition of coke and breeze is met by using forced draught and a special form of arch. The latter is built over the back part of the grate, thus deflecting the flame towards the front of the grate and thence through an opening to the boiler. This and the absence of draught above the grate cause a rapid heating of the coke on entering the furnace. Chain grates, with forced draught and suitable construction of the arch, have also been used successfully for burning coke breeze. The arch reaches two-thirds the length of the grate and slopes downwards towards the back. The radiation from the arch then raises the breeze rapidly to the ignition temperature. Lump coke can be burned on a chain grate with natural draught if the coke is pre-heated in a small chamber like a miniature gas producer, from which it is fed hot upon the grate. At the rear end a water-cooled bridge is fitted over the grate to retain unburnt coke, preventing it from falling over with the clinker into the ash-pit.

—H. J. H.

Coal; Combustion of the volatile matter in —. S. H. Katz. U.S. Bureau of Mines. Tech. paper, 183. 15 pages.

THE literature of the chemical and physico-chemical features of carbonisation of coal and decomposition and combustion of liquid and gaseous products has been collated, and a scheme is deduced to represent the supposed process of combustion in coal fires. It is proposed to use it as a guide in the further study of combustion.

—H. J. H.

Steaming horizontal [gas] retorts. R. J. Rew. Gas J., 1918, 142, 280–281.

IT has been found possible to increase the make of gas per ton in a small gasworks by steaming the coal in horizontal retorts of a special pattern. The setting contained three retorts, one or more of which could be steamed. The make of "straight" coal gas per ton was 11,500 cb. ft., and by steaming one retort for 14 hours this could be increased 20% with a loss of coke amounting to 15½ lb. per 1000 cb. ft. of water-gas produced. Trials with boiling burners showed that the gas was apparently satisfactory for use in ordinary domestic appliances.—H. J. H.

Paraffin, aromatic, naphthene, and olefine hydrocarbons; Solubility of — in liquid sulphur dioxide. R. J. Moore, J. C. Morrell, and G. Egloff. Met. and Chem. Eng., 1918, 18, 396–402.

THE utility of liquid sulphur dioxide as a solvent in the refining and analysis of liquid hydrocarbons has been investigated. The solubility of individual hydrocarbons of different types, of binary mixtures, and of a ternary mixture of paraffin, aromatic, and naphthene hydrocarbons has been studied. Solubilities were determined by bringing the liquid sulphur dioxide and the hydrocarbons together in a burette immersed in a freezing mixture of ice, salt, and calcium chloride at temperatures down

to -18°C . Benzene, toluene, xylene, mesitylene, and olefines were miscible with the solvent in all proportions at this temperature. Light paraffins up to decane, gasoline, and kerosene were practically insoluble. Naphthenes showed a limited solubility at -18°C ., more marked at -45°C . There is evidence of the formation of a molecular compound with the solvent. The separation of different types of hydrocarbon by liquid sulphur dioxide is limited by the partition of the hydrocarbon between the two phases, but by attention to the relative proportions some approximation to quantitative separation can be effected. In general, when the constituent to be extracted is in small proportion, aromatic hydrocarbons and olefines, together or separate, may be separated from paraffins and naphthenes. Naphthenes may be separated from paraffins. Over methods of sulphonation and nitration this process has the advantage of permitting recovery of both hydrocarbons and solvent, and also avoiding the production of undesirable by-products.—H. J. H.

Benzines and benzols; Examination of —. J. Formanek, J. Knop, and J. Korber. Chem.-Zeit., 1917, 41, 713–714, 730–731. Z. angew. Chem., 1918, 31, Ref., 62–63.

Detection of aromatic hydrocarbons (benzene) and of unsaturated hydrocarbons in benzine. The dracorubin test for the detection of aromatic hydrocarbons in benzine must be cautiously employed, for dracorubin is soluble, with a deep-red colour, in methyl, ethyl, and amyl alcohols, carbon bisulphide, ether, acetone, and chloroform, all of which, with the exception of the last, may be present in benzine and its substitutes. Two vat dyes, Indanthrene Dark Blue BT and Indanthrene Violet RT, are superior to dracorubin for the purpose of this test. Both of these are practically insoluble in benzine, but dissolve in benzene, toluene, xylene, carbon bisulphide, and chloroform with a bluish-red colour and yellow fluorescence; in ether and acetone the solubility is considerably less; in the alcohols, petroleum, and turpentine both are almost or quite insoluble. The colorimetric estimation of aromatic hydrocarbons by means of Indanthrene Dark Blue BT is practicable after two hours' standing, and compares favourably with results obtained by the Kraemer-Böttcher method. *Solidification points of benzene hydrocarbons and benzine.* The following solidification points are given: Benzene, $+5.5^{\circ}$; toluene, -88° ; *p*-xylene, $+13^{\circ}$; *m*-xylene, -54° ; *o*-xylene, -28° ; technical xylol, -115° ; benzines: fraction 200° to 220° C., -93° ; fraction 21° to 40° C., -203° ; light benzine (sp. gr. 0.680 to 0.700), -135° to -170° ; medium benzine (sp. gr. 0.700 to 0.740), -125° to -159° ; heavy benzine (sp. gr. 0.740 to 0.760), -95° to -120° ; crude petroleum, -58° ; refined petroleum, -85° to -90°C .—L. A. C.

Mineral oils; Sulphur and oxygen compounds of —. J. Marcusson. Mitt. K. Materialprüf., 1917, 374–380. Z. angew. Chem., 1918, 31, Ref., 62.

THE sulphur content of crude petroleum fluctuates considerably, heavy oils usually containing more than light oils. For the same oil the sulphur content increases in the separate fractions with increasing b. pt. and sp. gr., the residues being the richest in sulphur. Light oils rich in benzine contain least sulphur. The oxygen content also increases with rising b. pt. Compounds containing both sulphur and oxygen are found principally in dark oils, among the solid resinous and asphaltic constituents. The so-called resins form the first transition stage from the petroleum hydrocarbons to the asphaltenes, the latter being formed from the resins either by intramolecular change or by

further action of sulphur or oxygen. Both asphalt-
enes and resins are polycyclic bodies which contain
sulphur or oxygen linkings, possibly as ring com-
pounds or as sulphides or ethers. Asphaltenes con-
tain a higher percentage of sulphur and oxygen
than resins.—L. A. C.

Intermittent tar-dehydrating plant. Wimhurst.

PATENTS.

Artificial fuel and method of making same. J.
Schaub, Newark, N.J., Assignor to American
Linseed Co. U.S. Pats. (A) 1,262,267 and
(B) 1,262,268, Apr. 9, 1918. Dates of appl.,
July 17 and Oct. 4, 1917.

(A) CELLULOSE pentanitate is dissolved in methyl
alcohol, and ethyl alcohol is then added till the
solution is sufficiently viscous to be moulded
through a die into a "tubulous envelope," the
tubules of which are of capillary size. Ethyl
alcohol is then injected into the tubules. (B) Cellu-
lose pentanitate is dissolved in methyl alcohol,
and the colloidal material is solidified by the addi-
tion of water.—W. F. F.

Gas-making apparatus. E. B. Benham, New
London, Conn., Assignor to Hydrocarbon Con-
verter Co., New York. U.S. Pat. 1,262,576,
Apr. 9, 1918. Date of appl., July 14, 1911.

A SPHERICAL chamber is arranged within an outer
spherical chamber, and is provided with a neck
projecting through an opening in the side of the
larger chamber, the latter being closed by a plate
having openings which are normally closed. The
space between the chambers is filled with porous
material, and a mixture of air and oil is supplied
to it. The outer casing is surrounded by a con-
centric heating jacket, and the air and gasified oil
pass through perforations into the central space of
the inner chamber, from which they are withdrawn
by a pipe passing through the projecting neck of
the inner chamber.—W. F. F.

*Gas producers; Operation of — with previous
drying of moist fuels.* A. Eckardt, Zwickau.
Ger. Pat. 302,827, Mar. 14, 1914.

The apparatus is so arranged that the moisture
given off from a previous drying of the moist fuel
is utilised to supply the steam under the grate of
a gas producer of the Mond type. The degree of
drying is regulated according to the quantity of
steam it is desired to use in the producer.

—A. de W.

Gas-purifying apparatus. H. N. Cheney, Boston,
and D. S. Reynolds, Brookline, Mass. U.S. Pat.
1,261,767, Apr. 9, 1918. Date of appl., Feb. 23,
1917.

A CASING with vertical side and end walls and
having its top and bottom inclined but parallel to
one another, is provided with a number of tiers
of inclined beams parallel to the top and bottom.
The purifying material is carried between grids
supported by adjacent beams so as to permit the
passage of gas but prevent leakage of purifying
material. The purifying material is charged
through openings in the upper ends of the inclined
chambers formed by the grids and the side walls of
the casing, and discharged by gravity through open-
ings at the lower ends. Gas is supplied to the top
and bottom chambers formed by the top and bottom
walls and the adjacent grids and to alternate
spaces between the grids, and discharged from the
remaining alternate spaces.—W. F. F.

Tar extractor. G. M. S. Tait, Washington, D.C.,
Assignor to H. M. Marble, Newark, N.J. U.S.
Pat. 1,262,571, Apr. 9, 1918. Date of appl.,
Mar. 24, 1911. Renewed Aug. 11, 1917.

THE gas passes through a chamber containing a
steam jet to the extractor, which comprises a series
of adjacent annular chambers of successively in-
creasing diameter, communicating with one another
and arranged with their common axis horizontal.
Each chamber contains a rotating extractor wheel,
also of successively increasing diameter, mounted
on a common shaft, the wheels having blades which
force the gas from one chamber to the next. Each
chamber is provided with a discharge conduit for
tar leading from its lower portion to a water
chamber below, and terminating below the water
level. The chamber containing the steam jet com-
municates directly with the space above the water,
so that gas escaping through the tar outlets may
return to the inlet of the extractor.—W. F. F.

Hydrocarbon; Art of converting —. W. A. Hall,
New York, Assignor to Motor Petrol Co., Brattle-
boro, Vt. U.S. Pat. 1,261,930, Apr. 9, 1918. Date
of appl., May 24, 1913.

THE vapour of a heavy hydrocarbon is subjected
to the action of steam at a temperature approach-
ing red-heat and a pressure above that of the
atmosphere, in the presence of a finely divided metal
catalyst which is neither oxidised nor carbonised
under the above conditions. Carbon separates in
the solid form, and on condensing the vapours a
hydrocarbon of lower specific gravity is obtained.

—L. A. C.

*Hydrocarbon liquid; Semi-solidified — and
method of producing and utilising the same.*
M. H. Keyt, Chicago, Ill. U.S. Pat. 1,262,808,
Apr. 16, 1918. Date of appl., Feb. 4, 1916.

A DILUTE aqueous solution of albumin is added to
the hydrocarbon oil to be solidified.—L. A. C.

Petroleum; Process of treating —. M. J. Trumble,
Los Angeles, Cal., Assignor to Simplex Refining
Co. U.S. Pat. 1,262,875, Apr. 16, 1918. Date of
appl., Oct. 10, 1910.

A MIXTURE of hydrocarbons is heated under pressure
to a temperature sufficient to vaporise the lighter
constituents at atmospheric pressure. The pressure
is reduced, and the portion not vaporised is heated
in the form of a thin film in order to supply the
latent heat absorbed by the vapours.—L. A. C.

*Gasoline fractions containing aromatic hydrocar-
bons; Purifying —.* F. C. Ruff, Los Angeles,
Assignor to By-Products Manufacturing Co., San
Francisco, Cal. U.S. Pat. 1,262,289, Apr. 16, 1918.
Date of appl., Jan. 15, 1917.

To remove unsaturated aliphatic hydrocarbons from
a gasoline fraction containing an aromatic hydro-
carbon, it is treated with sulphuric acid containing
not more than 1% of nitric acid, i.e., an amount
insufficient materially to attack the aromatic com-
pound.—L. A. C.

*Naphthenic acids; Preparation of technically pure
—.* H. Bauer, Kolin, Bohemia. Ger. Pat.
302,210, Dec. 12, 1916.

CRUDE naphthenic acid, a by-product of the petro-
leum industry, is well stirred with aniline or
o-toluidine, and, after standing for some time, the
lower layer is separated and the solvent distilled
off. Naphthenic acids of 98–99% purity remain in
the still.—L. A. C.

Mineral oils, tar, etc.; Process for the distillation of —. R. Neumann, Brönn. Ger. Pat. 302,941, Mar. 27, 1917. Under Int. Conv., Mar. 20, 1917.

A TUBULAR still is connected with an auxiliary vessel by means of an overflow pipe at the top and a tube containing a circulating pump at the bottom. These are both filled with the oil or tar, and the fluid kept in circulation by means of the pump, which conveys the liquid from the auxiliary vessel to the still. When the former is empty the pump is shut off and distillation continued until the level of the liquid in the still is within a few cm. of the top of the fire tubes.—L. A. C.

Lubricating oil and glycerin; [Dieresyl carbonate as] substitute for —. Chem. Fabr. von Heyden A.-G. Ger. Pat. 302,361, Feb. 27, 1917.

DICRESYL carbonate is recommended as being cheaper than the trisresyl phosphate described in Ger. Pat. 288,448 (this J., 1916, 415) as a substitute for lubricating oil and glycerin.—L. A. C.

Lubricating oil; Substitute for —. E. Stern, Hannover. Ger. Pat. 302,986, Mar. 31, 1916.

A SUBSTITUTE for mineral lubricating oil consists of chlorination products of naphthalene, especially those prepared in the presence of a catalyst (e.g., aluminium chloride or the like), or under pressure, or under the combined action of pressure and a catalyst at a high temperature. The product is only slightly inflammable, neutral, and inactive.—L. A. C.

Apparatus for cleansing and filtering oil and similar liquids. Eng. Pat. 115,140. See I.

Preparation of concentrated ammonia from gas liquor. Ger. Pat. 302,195. See VII.

Manufacture of chlorinated hydrocarbons from natural gas. U.S. Pat. 1,262,769. See XX.

phase from bituminous lignite has a high paraffin content; that obtained in the third phase has a high oil content.—L. A. C.

Hydrocarbons; Production of — from bituminous coals. Chem. Fabr. Buckau, Magdeburg. Ger. Pat. 302,397, Jan. 16, 1914.

The finely-divided coal is worked up into a homogeneous mass with concentrated alkali solution, either alone or with the addition of alkaline-earth hydroxides. The mass is heated in autoclaves at a high temperature and pressure (30–50 atmos.) and then distilled, at first by means of superheated steam at 400°–450° C., and finally by direct heat until all the liquid has distilled over. The distillate is purified, and the alkali and alkaline-earth carbonates in the residue are converted into hydroxides and used again in the process. A total yield of 25–30% of liquid and gaseous hydrocarbons is obtained, including 4% distilling at 100° C., and 12% up to 200° C.—L. A. C.

Absorbent material [charcoal] and process of producing the same. J. B. Garner, Pittsburgh, Pa., Assignor to Metals Research Co., New York. U.S. Pat. 1,262,770, Apr. 16, 1918. Date of appl., June 30, 1915.

Wood charcoal is heated in an inert gas for a prolonged period at about 250° to 275° C., and subsequently under reduced pressure at 100° to 125° C. for sufficient time to remove occluded gases and volatile constituents.—L. A. C.

Heating stills, boilers, and the like; Electrical apparatus for —. C. O. Lorenz, Port Arthur, Tex., Assignor to The Texas Co. U.S. Pat. 1,262,072, Apr. 9, 1918. Date of appl., May 8, 1917.

The greater portion of the heating element is composed of sand and iron, fused and cast.—B. N.

Crystalline non-metallic bodies; Production of —. [Manufacture of filaments for incandescence electric lamps composed of a solid solution of thoria in tungsten.] J. Pintsch A.-G., Berlin. Ger. Pat. 304,857, May 28, 1916. Addition to Ger. Pat. 291,994 (see Fr. Pat. 469,212; this J., 1915, 36).

The process described in the chief patent is applied to non-metallic substances. The substance used may be one which during the process will be converted by heat or by interaction with the surrounding atmosphere into another substance; or a crystal of the substance may be heated in a gas from which the substance of which the crystal is composed is deposited, so that by regulating the conditions growth of the crystal in a desired direction can be obtained. As a special case the application of the process to the production of wires of a solid solution of thoria in tungsten is described. This solid solution forms long crystals, and is particularly suitable for the manufacture of filaments for electric incandescence lamps.

Dry distillation of untreated or concentrated cellulose waste lyes. Ger. Pat. 303,053. See V.

Production of an insecticide. Ger. Pat. 302,238. See XIXb.

Photometry and apparatus therefor. Eng. Pat. 112,614. See XXIII.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Retort for dry distillation; Experimental —. F. E. Coombs. Met. and Chem. Eng., 1918, 48, 425.

THE retort consists of a cylindrical container of metal closed at the bottom. A similar cylinder, of slightly larger diameter so as to slide loosely over the retort, forms the lid, to which a bent delivery tube is fitted. The lid is secured to the retort by screws. The apparatus is heated in a bath of liquid—e.g., fused metal or caustic soda—the level of which is below the top of the container, which is thus sealed by the liquid entering the annular space inside the lid. The contents of the retort can be distilled at a known and regulated temperature, while the apparatus permits great accessibility for cleaning and charging.—H. J. H.

"Perocide" liquor as a substitute for copper-lime liquor. Appel. See XIXb.

PATENTS.

Dry distillation of coal; Process for the —. T. Lilberg, Halle. Ger. Pat. 302,322, Nov. 3, 1916.

DISTILLATION is carried out in three sharply defined phases, i.e., up to 250° C., from 250° to 400° C., and above 400° C. The tar obtained in the second

III.—TAR AND TAR PRODUCTS.

Tar-dehydrating plant; Intermittent —. H. R. Wimhurst. Eastern Counties Gas Managers' Assoc., May 2, 1918. Gas J., 1918, 142, 282—283.

THE tar is distilled in two horizontal cylindrical stills of 1500 gallons capacity, direct fired with coke and worked alternately. The stills are built side by side in a setting over a common flue system, so arranged that the products of combustion from the one in use pass under the other on their way to the stack, thereby preheating a charge of crude tar. Distillation of water and light oil is continued until the tar reaches a temperature of 110° C. Each still has an independent condenser communicating with a common separating tank, which in turn is connected to a small purifier box to deal with the waste gas.—H. J. H.

Solubility of paraffin, aromatic, olefine, and naphthene hydrocarbons in liquid sulphur dioxide. Moore and others. See IIa.

Examination of benzines and benzols. Formanek and others. See IIa.

PATENTS.

Tar oils; Process for the production of — resistant to cold. L. Singer, Düsseldorf. Ger. Pat. 303,789, Oct. 6, 1916.

TAR oils which contain readily deposited solid matter, particularly the so-called "fatty tar oils," are mixed with hydrocarbons obtained by the extraction of mineral oils with liquid sulphur dioxide or acetone, as described in Ger. Pats. 216,459 (this J., 1910, 144) and 166,452 (this J., 1906, 634). A permanently clear oil is obtained of high viscosity and temperature of ignition.—L. A. C.

Toluol; Manufacture of —. F. Thuman, Westminster. From O. B. Evans, Philadelphia, U.S.A. Eng. Pat. 115,066, Apr. 20, 1917. (Appl. No. 5567 of 1917.)
SEE U.S. Pat. 1,230,087 of 1917; this J., 1917, 866.

Manufacture of β -aminoanthraquinone. O. Imray, London. From Soc. of Chem. Ind. in Basle, Switzerland. Eng. Pat. 115,259, Apr. 28, 1917. (Appl. No. 6035 of 1917.)

[*Naphthol-resin as shellac substitute.* Ger. Pat. 302,742. See XIII.]

IV.—COLOURING MATTERS AND DYES.

Genus Coprosma (Family Rubiaceae); Tinctorial properties of —. B. C. Aston. New Zealand J. Sci. Tech., 1918, 1, 3—4.

THREE species of the genus *Coprosma*—*C. grandifolia*, *C. unarifolia*, and *C. arcolata*—are widely distributed in New Zealand and their bark, especially that of the roots, possesses marked tinctorial properties. These plants are related to madder, the natural source of alizarin. The alcoholic extract from *C. grandifolia* is coloured

a brilliant purple in alkaline and yellow in acid solution. By extraction of the acid solution with ether orange-coloured crystals were isolated in quantity equal to 0.068% of the wet bark. The possibility of using the extracts in the local textile industry is suggested.—H. J. H.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

PATENTS.

Wool substitute; Process for the preparation of — from Eriophorum fibres. E. L. Fegraeus. Lerum, Sweden. Ger. Pat. 302,261, Feb. 25, 1917. Under Int. Conv., May 19, 1916.

THE fibres are treated for 4—6 hrs. in a cold weak alkaline bath, and then for $\frac{1}{2}$ —1 hr. in a stronger bath, then rinsed and impregnated with olein or other oil emulsion in a press. The material is hydro-extracted and dried.—L. A. C.

Fibres and fabrics; Preparation of — as substitutes for wool. P. Kraus, Tübingen. Ger. Pat. 302,611, Feb. 1, 1917.

Wool, hair, horn, or leather refuse is treated with solutions of gelatin, glue, acetylcellulose or other viscous solutions of cellulose or its compounds, with the addition of glycerin or its substitutes, esters such as triphenyl phosphate, oils, or fats in order to render the material pliable. The material is formed into fibres, and these are spun into yarn and cloth in the same manner as paper yarn. In order to render the gelatin or glue insoluble, the solution is treated with a chromium compound, e.g., a bichromate or chrome alum. By after-treatment with formaldehyde, tannin, or their substitutes, or with aluminium salts, the material is hardened and rendered more resistant to the action of hot water.—L. A. C.

Textile fibres from plants of the lupin family; Process of obtaining —. Pflanzenfaser Patent Ges.m.b.H., Berlin. Ger. Pat. 302,803, Mar. 26, 1916.

PLANTS of the lupin family are treated with hot strong alkali for such time as to separate the bast tissue from the other constituents whilst insufficient to break up the former into its individual cells. The lye is then rapidly removed and the fibres washed with sprays of water.

—A. de W.

Cellulose waste lyes; Dry distillation of untreated or concentrated —. W. Schacht, Weissenfels. Ger. Pat. 303,053, June 24, 1915.

THE apparatus consists of a battery of vertical retorts connected with one another and fitted internally with interchangeable rings or plates to hold the material, which is spread on in relatively thin layers. These rings or plates are connected to one another by pipes and are quickly and easily removable, thus permitting the bottom layer to be removed for lixiviation or further treatment. The distillation in thin layers, it is claimed, results in a larger yield of acetone, oils, and nitrogenous compounds.—A. de W.

Vegetable fibres; Process of removing pectic matter from —. B. Leech, Macclesfield. U.S. Pat. 1,263,685, Apr. 23, 1918. Date of appl., Aug. 21, 1917.

SEE Eng. Pat. 104,202 of 1916; this J., 1917, 451.

Lubricant [from sulphite waste liquor]. Ger. Pat. 302,188. See I.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Tinctorial properties of the Genus Coprosma (Family Rubiaceae). Aston. See IV.

PATENT.

Dyeing apparatus and the like. J. G. Grabe, St. George, N.Y. U.S. Pat. 1,261,921, Apr. 9, 1918. Date of appl., Apr. 7, 1917.

In the upper part of a dye-vat is a mixing chamber open at the bottom and with a screen extending across the opening, and below this is another screen extending across the vat. A helical vane is attached to the wall in the lower part of the vat. A hollow conoidal vessel with a corrugated wall pierced by numerous openings at different levels in the spaces between the corrugations, and connected at its upper end with the mixing chamber, acts as a circulating device, causing the liquid in the vat to enter the mixing chamber. Water condensed on the cover of the vat falls into a condensing chamber adjacent to the mixing chamber, and thence is delivered on to the middle portion of the lower screen.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Water sprayer for lead sulphuric acid chambers. W. Szlgeti. Chem.-Zeit., 1918, 42, 115.

TANTALUM, owing to its chemical indifference to chamber gases, combined with mechanical strength, can replace platinum with advantage in the construction of water sprayers for lead chambers. A sprayer is described in which water at 60–75 lb. pressure passes through a plate by three holes and then along three grooves, whence it passes tangentially into a small chamber, one side of which is a tantalum plate pierced at the centre; the water emerges through the perforation in a fine spray. The body of the sprayer is of hard lead. The tantalum plates have shown great durability in practice.—H. J. H.

Salt; Dissociation of —. H. V. Thompson. Ceramic Soc., Refractories Section, May 18, 1918. [Advance proof.]

The degree of dissociation of salt in steam at 1100° C. was found to be too small and the reversal of the reaction on cooling too rapid to permit of determining the equilibrium by measurement of the hydrogen chloride formed. An estimate was obtained by volatilising salt at 1100° C. in a current of air for 6 hours—first in dry air and then in air saturated with water vapour at 21.7° C. The condensed products from the air passed were collected and the difference between the two was ascribed to salt formed by recombination of soda and hydrochloric acid formed by the action of steam on the salt. The salt was heated in a platinum tube through which the air passed at the rate of 2 litres per hour. The salt recovered in the condensed product was 0.0551 grm. per litre of dry air and 0.0782 grm. per litre of air saturated at 21.7° C., i.e., 1 grm.-mol. of water vapour had decomposed 0.37 grm.-mol. of salt at 1113° C. Chips of quartz were exposed to the action of salt vapours in dry and moist air at 1100° C. In moist air the effect was more pronounced and the quartz was superficially attacked with the formation of a silicate, apparently $\text{Na}_2\text{O} \cdot \text{SiO}_2$, which, however, was insoluble in water. The result of heating commercial ferric oxide in the current of salt vapours

was to cause the formation of magnetic oxide in a black crystalline form. Alumina was also superficially attacked with the formation of an aluminite of the empirical formula about $2\text{Na}_2\text{O} \cdot 9\text{Al}_2\text{O}_3$.—H. J. H.

Radium from American pitchblende ores; Experiments on the extraction of — by chlorination. R. Cable and H. Schlundt. Met. and Chem. Eng., 1918, 13, 160–162.

The pitchblende ores of Glipin County, Colorado, contain uraninite very intimately associated with iron pyrites. By ordinary concentration, products containing from 1 to 25% of uranium oxide (U_3O_8) are obtained; and these are blended to produce high-, medium-, and low-grade concentrates, which, in the present case, contained 17.45, 2.92, and 1.20% U_3O_8 and 49.27, 8.312, and 3.43 parts per billion of radium, respectively. Each concentrate was heated in a current of chlorine in a glass tube, producing sulphur monochloride (which was collected separately) and a crystalline sublimate of anhydrous metallic chlorides which was found to contain nearly all the radium. By treating the ore residue and the sublimate together with water, a solution was obtained from which the radium was separated almost quantitatively as radium-barium sulphate. In this way 93.68, 91.78, and 93.34% of the radium originally present was recovered from the high-, medium-, and low-grade concentrates respectively, the radium content of the sulphates being well within the limit required for further concentration by the usual methods.

Precipitation of phosphoric acid in the form of ammonium phosphomolybdate. Clarens. See XXIII.

Estimation of phosphoric anhydride as ammonium phosphomolybdate. Clarens. See XXIII.

Iodine titration of silver nitrate. Scheider. See XXIII.

PATENTS.

Hydrofluoric acid; Process for the preparation of — from bisulphate and fluorspar. B. Teisler, Dohna. Ger. Pat. 302,278, Aug. 21, 1915.

To a mixture of fluorspar and bisulphate is added a solid such as a metallic sulphate, or carbon in the form of graphite, retort-coke, anthracite, or soot, which is not attacked by sulphuric or hydrofluoric acid. Fusion of the bisulphate is thereby inhibited.—L. A. C.

Sodium cyanide briquette. A. Kaufman, Assignor to Air Reduction Co., New York. U.S. Pat. 1,262,057, Apr. 9, 1918. Date of appl., Nov. 7, 1916.

A BRIQUETTE, composed of or containing sodium cyanide, having a porous interior and a relatively impervious exterior, and provided with relatively small supporting ribs on one face, is made by compressing the material into the required shape and heating the block until surface fusion occurs.

—W. E. F. P.

Sulphurous fumes; Process for treating —. S. W. Young, Palo Alto, Cal., Assignor to The Thiogen Co., Wilmington, Del. U.S. Pat. 1,262,295, Apr. 9, 1918. Date of appl., Oct. 18, 1915. Renewed Nov. 15, 1917.

In a cyclic process for treating sulphurous fumes, the latter are brought into contact with water and

the solution is treated with an alkaline-earth (barium) sulphide to produce a mixture of sulphur and oxygen-sulphur compounds. This mixture is heated to expel the free sulphur and then reduced with carbon to regenerate the alkaline-earth sulphide.—W. E. F. P.

Hydrogen peroxide; Process of producing —. O. Liebknecht, Frankfurt, Germany. U.S. Pat. 1,262,589, Apr. 9, 1918. Date of appl., Jan. 3, 1918.

A CONCENTRATED mineral acid is added gradually to a suspension of sodium perborate to produce, in one operation, a concentrated solution (above 10%) of hydrogen peroxide.—W. E. F. P.

Magnesium salts; Process for manufacturing —. *Process of making magnesium chloride*. H. A. Galt, Akron, Assignor to Columbia Chemical Co., Barberton, Ohio. U.S. Pats. (A) 1,262,938 and (B) 1,262,939, Apr. 16, 1918. Date of appl., Jan. 22, 1915.

(A) A MIXTURE of precipitated calcium and magnesium carbonates—obtained by causticising sodium carbonate with hydrated, calcined dolomite—is treated with water and carbon dioxide under pressure, to dissolve the magnesium carbonate. The filtered solution is then heated to re-precipitate magnesium carbonate, which is collected and digested with a solution of calcium chloride (obtained in the manufacture of alkali by the ammonia-soda process) to produce magnesium chloride and calcium carbonate. (B) The calcium chloride solution obtained in the manufacture of alkali by the ammonia-soda process, and the sludge produced by causticising sodium carbonate with magnesium hydroxide (hydrated, calcined magnesite), are heated together under pressure to form magnesium chloride.—W. E. F. P.

Magnesium chloride liquors; Utilisation of waste — of the potash industry. [Preparation of hydrochloric acid from alkali chlorides.] Chem. Fabr. Buckau, Magdeburg. Ger. Pat. 302,359, Mar. 28, 1914. Addition to Ger. Pat. 283,096.

ACCORDING to the chief patent hydrochloric acid was recovered from waste magnesium chloride liquors by heating them with sulphuric acid, whilst in previous additions to this patent claims were made to the use of diminished pressure (Ger. Pat. 284,177) and to the substitution of a mixture of sulphur dioxide and oxygen in presence of water for the sulphuric acid (Ger. Pat. 290,876; this J., 1916, 634). It has since been found that in presence of magnesium sulphate hydrochloric acid can also be liberated from alkali chlorides by this process. According to the present patent waste liquors containing magnesium chloride or magnesium sulphate, mixed with alkali chlorides, or double alkali-magnesium chlorides, such as carnallite, with or without addition of alkali chlorides, are heated with sulphuric acid, the hydrochloric acid is condensed, and magnesium sulphate and alkali sulphate are recovered either separately or as a double salt from the residual solution. Instead of distilling off the hydrochloric acid, the concentrated reaction mixture may be allowed to stand at a low temperature, whereby the sulphates crystallise out and a concentrated solution of hydrochloric acid is left.

Percarbonates; Production of —. O. Liebknecht, Frankfurt, Germany. U.S. Pat. 1,263,258, Apr. 16, 1918. Date of appl., Jan. 3, 1918.

SODIUM percarbonate is prepared by adding a large proportion of common salt to a dilute solution of hydrogen peroxide containing sodium carbonate.

—W. E. F. P.

Tin chloride solution; Process for the regeneration of —. Siemens und Halske A.-G., Siemensstadt. Ger. Pat. 302,040, July 19, 1914.

THE tin chloride solution flows along a trough at the bottom of which are horizontal cathodes. The anodes are suspended from a cover and separated from the cathodes by diaphragms through which the chlorine ions alone pass, the chlorine gas evolved being withdrawn through tubes.—L. A. C.

Tin oxide; Preparation of very finely divided — from stannate liquors. G. A. Krause, Munich. Ger. Pat. 302,155, May 3, 1916.

STANNATE liquor freed from impurities and in which the tin has been precipitated in the usual manner, is brought in contact in the form of a very fine spray, e.g., by means of nozzles, rotating plates, etc., with a counter-current of hot air or gas for the purpose of removing the moisture. The tin oxide produced thus is in a very finely divided form and suitable for enamel manufacture.—L. A. C.

Tin oxide; Process for the preparation of — from stannate liquors. G. A. Krause, Munich. Ger. Pat. 303,492, May 6, 1916.

THE liquor is sprayed, e.g., by means of blasts, rotating plates, etc., into a current of the warm gas, i.e., carbon dioxide, used for precipitating the tin. The tin oxide so obtained is of very low sp. gr.—L. A. C.

Gas liquor; Preparation of concentrated ammonia from —. C. Still, Recklinghausen. Ger. Pat. 302,195, Dec. 7, 1915.

THE liquor is passed down a column in which a portion of the carbon dioxide is removed; it is then divided into two portions, one of which enters another column in which the remainder of the carbon dioxide and a portion of the ammonia are removed; on leaving this column, the liquid unites with the untreated portion and together they enter a third column where they are treated with lime, whereby complete separation of the ammonia is effected. A regulated quantity, or if necessary the whole of the ammoniacal vapour from the third column, is led through the second column, where it becomes charged with the ammonia and carbon dioxide evolved therein. By regulating the two streams of liquid and the flow of vapour an ammonia solution of any required strength may be obtained.—L. A. C.

Pyrophosphates; Manufacture of alkali and alkaline-earth acid —. Chem. Fabr. Budenheim L. Utz m.b.H., Mainz. Ger. Pat. 392,672, July 5, 1916.

AMMONIUM monophosphate is heated with an equivalent amount of alkali or alkaline-earth hydroxide or carbonate.—L. A. C.

Chromic liquors; Process for the electrolytic oxidation of acid — to chromic acid. P. Goldberg, Berlin-Karlshorst. Ger. Pat. 303,165, Sept. 2, 1916.

CHROMIC liquor exhausted through oxidation, containing, e.g., 65 grms. of chromium oxide and 275 grms. of sulphuric acid per litre, and in which 110 grms. of copper oxide has been dissolved, is electrolysed, the electrodes being lead peroxide and copper plates. The chromium oxide is oxidised to chromic acid to the extent of about 80%, in accordance with the following equation: $3\text{Cr}_2\text{O}_3 + \text{Cr}_2(\text{SO}_4)_3 + 6\text{H}_2\text{O} = 3\text{Cu} + 2\text{CrO}_3 + 6\text{H}_2\text{SO}_4$. The very low copper content of the resulting solution is harmless for the oxidation of organic substances and for the solution of metals.—L. A. C.

Nitrogen; Preparation of — from the air. Elektrizitätswerk Lonza A.-G., Gampel, Switzerland. Ger. Pat. 392,671, June 20, 1916.

Air or any mixture of nitrogen and oxygen is passed into a solution of ammonium sulphite at at least 70° C., until removal of the oxygen is complete as far as possible. The best results are obtained between 70° and 75° C.; above 75° C. dissociation of the ammonium sulphite takes place, but the ammonia formed can be removed from the nitrogen by adding sulphur dioxide and passing through a further quantity of ammonium sulphite solution, or by bubbling the gas through water or sulphuric acid. Nitrogen sufficiently pure for the manufacture of calcium cyanamide, i.e., containing 0.1–0.2% of oxygen, can be obtained by this process.—L. A. C.

Molybdenum compounds; Separation of — from substances. E. H. Westling and C. Andersen. San Francisco, U.S.A. Eng. Pat. 115,274, May 3, 1917 (Appl. No. 6317 of 1917.)

SEE U.S. Pat. 1,250,063 of 1917; this J., 1918, 88 A.
Nitrogen; Apparatus for fixation of —. J. A. Currie, Toronto, Canada. U.S. Pat. 1,263,523, Apr. 23, 1918. Date of appl., Apr. 8, 1916.

SEE Eng. Pat. 105,953 of 1916; this J., 1917, 656.

VIII.—GLASS; CERAMICS.

Silica products.—I. Raw materials. A. Bigot. Ceram. Soc., Refractories Sect., May 14, 1918. [Advance proof.]

The raw materials used are quartzose rocks and sands; quartz and flints are the most free from impurities, quartzites usually containing a notable proportion of foreign matters. Quartzites which had been ground to pass a No. 200 sieve, then suspended in water, and the heaviest particles separated, showed 13.6% impurities as compared with 4.05% in the untreated material, showing that the latter contained about 7% of clay, which acts as an agglomerant in the manufacture of bricks. The material should be heated at 1710° C. for 1 hr. and all samples which remain neither compact nor tough after this heating should be regarded as useless. Many French quartzites expand from 9 to 15% when heated at 1710° C.; in Germany those with an expansion of 9.5–10% are preferred. Flint expands less and is less porous than quartzites and for this reason should be preferable for silica bricks, but practical experience does not confirm this.—A. B. S.

Magnesite and dolomite; Economy of fuel and increased output in dead-burning of — and in burning of cement. E. Steiger. Ceram. Soc., Refractories Sect., May 14, 1918. [Advance proof.]

The vertical shaft type of kiln gives a satisfactory product and costs little to instal, but the labour costs in working it are excessive. The rotary kiln is expensive to instal; labour costs are low, but the product is often irregular. The advantages of both types are secured by providing the shaft type of kiln with suitable charging and discharging devices. The latter consists of a vertical shaft in the bottom of the kiln, fitted with a rotary steel head which seals the kiln but, in turning, discharges a definite proportion of the burned material.—A. B. S.

Corindite; A new refractory and abrasive material called —. A. Bigot. Ceram. Soc., Refractories Sect., May 14, 1918. [Advance proof.]

BAUXITE when melted by mixing it with anthracite

and blowing air through the mixture (Lecesse, Fr. Pat. 471,513; this J., 1915, 356) yields a vesicular mass containing many small crystals of alundina. To this material the term "corindite" has been assigned. It has a higher melting point than the original bauxite owing to the reduction of the iron oxide to metal and spinel ($\text{Al}_2\text{O}_3, \text{FeO}$) and the separation of some of the more fusible constituents. The product made from white (Var) bauxite is suitable for lining furnaces and other refractory purposes; the material made from red bauxite forms an excellent abrasive and substitute for emery or corundum.—A. B. S.

Abrasives; Distinction between different — and the detection of carborundum in them. R. Peters. Pharm. Zentralh., 1917, 58, 217–219, 231–234. Z. angew. Chem., 1918, 31, Ref., 9.

As compared with natural emery the artificial corundum abrasive produced in the electric furnace has a deeper, greyish blue colour. By chemical analysis alone it is difficult to distinguish between the two products, but the artificial material is characterised by the presence of microscopic inclusions of gas and is also less magnetic than natural emery. Carborundum can be detected by heating the previously ignited sample with 20 parts of lead chromate in a hard glass tube, when the mass becomes red hot with liberation of carbon; this test gives appreciable results even with mixtures containing only 5% of carborundum. For the determination of small amounts of carborundum in an abrasive it is necessary to treat the residue insoluble in fused bisulphate, repeatedly with hydrofluoric and sulphuric acids until a constant weight is obtained. With abrasives containing a small proportion of carborundum it is possible to estimate the carbon by heating the previously powdered and ignited sample with potassium chlorate and lead chromate in a current of air for about one hour, the carbon dioxide in the gaseous products being determined by collection in barium hydroxide solution after successive washings with silver nitrate and ferrous sulphate solutions.—D. F. T.

Dissociation of salt. Thompson. See VII.

PATENTS.

[*Porcelain*] **insulating material and body composed thereof.** A. Champion and T. G. McDougall, Assignors to Champion Ignition Co., Flint, Mich. U.S. Pat. 1,262,305, Apr. 9, 1918. Date of appl., Aug. 22, 1917.

CALCINED clay is used as a non-plastic ingredient in the manufacture of insulating material for sparking plugs. A mixture of plastic clay 60%, feldspar 10%, calcined clay and flint 30% is specified.—A. B. S.

Insulating material; Manufacture of acid-resistant refractory —. H. Stegmeyer, Charlottenburg. Ger. Pat. 302,831, Mar. 5, 1915.

A Mixture of water-glass with one or more filling materials (porcelain dust, sand, graphite, etc.) is worked to a plastic mass and, after being formed into the desired shape, is hardened by heating under pressure in an atmosphere of carbon dioxide or other acid gases or vapours. The filling material may be previously mixed with a small quantity of a substance which forms or liberates an acid on heating, e.g., sulphur, ammonium acetate, sodium formate, etc., and in such case the hardening is effected at a temperature above the melting point of the admixed substance. The product resists the action of concentrated sulphuric acid better than the known kinds of chemical

stoneware, and is much less affected than fire-brick, etc., by variations of temperature.

Dryer for bricks. A. E. H. Beyer, Wengeln. Ger. Pat. 301,583, Jan 10, 1913.

A SERIES of chambers arranged side by side in two parallel rows is heated by the waste gases from a continuous kiln, the gases being delivered to the chambers through four separate flues, one above another, leading into downcast pipes in each chamber. The temperature is regulated by means of four sets of dampers. After passing through the desired chambers the gases are led to the chimney.—A. B. S.

Briquetting coarse materials, which have later to be burned, with clay. A. Olschewsky, Coswig. Ger. Pat. 302,704, Dec. 25, 1913.

THE interstices between the coarser particles are filled with finely ground material of a combustible nature and a little clay is then thoroughly incorporated. The addition of the combustible matter greatly reduces the proportion of clay required to make the material workable.—A. B. S.

Sintered magnesia; Production of —. Harburger Chem. Werke Schön und Co., Harburg. Ger. Pat. 302,836, Mar. 1, 1916. (Addition to Ger. Pat. 291,913; this J., 1916, 843.)

A MAGNESIA slurry with the desired proportion of lime, iron oxide, alumina, and silica, prepared in any convenient manner, alone or mixed with slurry prepared from magnesium chloride as described in the chief patent, is heated until it sinters.—A. B. S.

Unfired refractory products; Production of —. Petrel'sche Terrain-Ges. A.-G., München-Riesefeld. Ger. Pat. 302,877, July 11, 1916.

REFRACTORY ware which has a high heat-resistance, does not warp or spall under sudden changes of temperature, resists the action of furnace gases and vapours, and has a high crushing strength, is made by mixing silicious material free from fluxes with a calcareous binder, and a small quantity of grog, and hardening the product by means of steam under pressure.—A. B. S.

Glass; Manufacture of —. J. A. Chambers, Pittsburg, Pa., U.S.A. Eng. Pat. 103,672, Jan. 26, 1917. (Appl. No. 1339 of 1917.) Under Int. Conv., Jan. 26, 1916.

SEE U.S. Pat. 1,186,076 of 1916; this J., 1916, 842. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 20,415 of 1891, 15,293 of 1906, and 14,417 of 1907; this J., 1893, 46; 1906, 1045; 1908, 628.)

Glass; Method of and apparatus for drawing sheet —. W. J. Mellersh-Jackson, London. From The Libbey-Owens Sheet Glass Co., Toledo, Ohio, U.S.A. Eng. Pat. 114,977, Oct. 4, 1917. (Appl. No. 14,372 of 1917.)

SEE U.S. Pat. 1,248,809 of 1917; this J., 1918, 58 A.

Preparation of very finely divided tin oxide from stannate liquors. Ger. Pat. 302,155. See VII.

Preparation of tin oxide from stannate liquors. Ger. Pat. 303,492. See VII.

IX.—BUILDING MATERIALS.

Cement and concrete; Influence of substances on —. J. C. Witt. Philippine J. Sci., 1918, 13 A., 29—48.

A BIBLIOGRAPHY of the influence of electrolytes on the setting of cement is given. Generalisations from it are difficult to draw because the various experiments are not comparable owing to differences in the conditions, *i.e.*, chemical and physical character of the cements used for the experiments, and concentration and temperature of the solutions. Experiments on four cements have been made, using eleven electrolytes under comparable conditions—NaCl, ZnCl₂, CuCl₂, NaNO₃, KNO₃, NH₄NO₃, Na₂SO₄, ZnSO₄, CuSO₄, NaHCO₃, KHCO₃. The effect was generally to lower the tensile strength, and any increase, which was usually associated with sulphate, was only small. The cement with the highest calcium content seemed most sensitive. The sulphates and chlorides of zinc and copper caused a retardation of the set, which increased with the concentration. The other salts caused a retardation which rose to a maximum as the concentration increased and then diminished. The positive ion seems to have more influence than the negative, but there is no clear connection between this effect and the solubility of the calcium salt formed.—H. J. H.

Silica and Portland cement; Swelling phenomena in connection with —. V. Rodt. Chem.-Zeit., 1918, 42, 173—175.

FINELY ground cement or certain forms of silica, when treated with lime-water or certain other solutions such as alum, ammonium carbonate, etc., swell greatly and form a loose, flocculent material. Quartzite and other forms of free silica do not swell so much as silica liberated from certain silicates. The swelling is apparently due to the absorption of water in a manner not fully understood. Portland cement appears to be hydrolysed, lime entering into solution and free silica being separated; the latter absorbs water and swells. It is suggested that the cracking and destruction of concrete may be due to a similar swelling, resulting from the absorption of sulphates.

Silica products. I. Raw materials. Bigot. See VIII.

Economy of fuel and increased output in dead-burning of magnesite and dolomite and in burning of cement. Steiger. See VIII.

PATENTS.

Cement. W. H. Allen, Detroit, Mich. U.S. Pat. 1,261,750, Apr. 9, 1918. Date of appl., Dec. 12, 1917.

A CEMENT is composed of powdered iron oxide (magnetite) and a solution of an acid phosphorus compound (*e.g.*, a 50% solution of phosphoric acid) in proportions to form a paste.—A. B. S.

Hydraulic cement; Production of —. F. M. Meyer, Saarbrücken. Ger. Pat. 303,177, Dec. 20, 1912. Under Int. Conv., Aug. 8, 1912.

A MIXTURE of 30 parts of dust from gas-filters used in the dry gas cleaning process and 70 parts of slaked lime produces a hydraulic cement which, when mixed with 3 parts of normal sand, has a crushing strength of 209 kilos. per sq. cm. after eight days and 224 kilos. per sq. cm. after twenty-eight days.—A. B. S.

Plaster; Burning slow-setting — Maschinenfabr. Petry und Hecking G.m.b.H., Dortmund. Ger. Pat. 301,932, Mar. 17, 1915.

THE plaster is separated into particles of approximately uniform size, and each fraction is burnt separately, first in a strongly heated drum until dehydration begins, and then in a less strongly heated drum, which may be heated by the waste gases from the first drum, the temperature being moderated if necessary by introduction of air. In the second drum the heating gases move in the opposite direction to the plaster. As raw gypsum is less easy to grind than the burned material, it is desirable to crush the gypsum only so far as is necessary to obtain a good plaster when burned.

—A. B. S.

Hollow blocks, closed on all sides; Production of — from cement and artificial stone, by means of ice. S. Röhm, Munich. Ger. Pat. 302,137, Dec. 28, 1916.

THE concrete or artificial stone is packed around a core of ice and allowed to harden, due provision being made for water from melting ice to escape through vents in the concrete or stone.—A. B. S.

Lime for mortar; Production of hydraulic — from pure lime free from silica. G. Pralle, Gr.-Hartmannsdorf. Ger. Pat. 302,319, Feb. 16, 1916.

AIR-SLAKED lime which has become hydrated and carbonated is mixed with freshly burned and slaked lime and then stored in a silo. The product gives a mortar which sets as rapidly and firmly as one prepared with natural hydraulic lime.—A. B. S.

Artificial stones; Hardening calcareous — by gases containing carbon dioxide. A. Rinne, Charlottenburg. Ger. Pat. 302,635, Nov. 29, 1913.

THE absorption of carbon dioxide from the gases used in the hardening process is regulated, e.g., by varying the velocity of the gases or by addition of an inert gas, such as air, so that it does not exceed the following amounts when the temperature of the stone mass is as stated: 25° C., 0.5–2.0% by vol.; 30°, 1.0–3.5%; 35°, 2.0–5.0%; 40°, 3.0–7.0%; 50°, 4.5–10.0%; 60°, 8.0–17.0%; and 70° C., 15.0–24.0% by vol.—A. B. S.

Artificial stones; Production of — from filling material and asphalt. A. Olschewsky, Coswig. Ger. Pat. 302,705, June 6, 1915.

A MIXTURE containing pitch and asphaltic material is formed into the desired shape, dried, and heated above 120° C. in absence of air. The asphalt and the distillation products of the pitch then form a binding agent.—A. B. S.

Artificial stone; Production of — for use in the construction of ships. O. Herzfeld, Charlottenburg. Ger. Pat. 303,115, June 12, 1917. (Addition to Ger. Pat. 298,322.)

TO concrete made in the usual manner, pumice, trass, and bitumen (as fillers) and jute, esparto grass, or nettle or ramie fibres (as binders) are added in order to produce a material intermediate in character between wood and concrete, with a high degree of elasticity, crushing strength, and tensile strength, and low permeability specially suitable for use in the construction of ships.

—A. B. S.

Wood; Preservation of — H. Bardev, Bad Stuer. Ger. Pat. 303,064, Dec. 16, 1913.

WOOD is immersed in boiling water until saturated and all air expelled, and is then immersed in molten

paraffin, heated to a temperature above 100° C., until all water is driven off as shown by the cessation of bubbling. The wood is allowed to cool *in situ* until the paraffin solidifies. After such treatment the wood is very resistant to water and bacteria.—F. C. T.

Dense sandy product from slag; Production of a —. Oberschlesische Eisenbahn-Bedarfs-A.-G., Friedenshütte. Ger. Pat. 303,447, Feb. 24, 1914.

SLAG is reduced to fine powder in a disintegrator and thrown a considerable distance so as to cause the particles to solidify externally before they come into contact with water. By this means the production of a light porous slag is avoided and a dense, sandy product is obtained.—A. B. S.

Slag bricks; Manufacture of —. The Middlesbrough Slag Co., Ltd., Stockton-on-Tees, and J. L. Major. Bull. Eng. Pat. 115,100, Apr. 30, 1917. (Appl. No. 6121 of 1917.)

Roofing materials. H. Abraham, New York. Eng. Pat. 113,778, Oct. 2, 1917. (Appl. No. 14,247 of 1917.) Under Int. Conv., Feb. 27, 1917.

SEE U.S. Pat. 1,226,738 of 1917; this J., 1917, 719.

Production of sintered magnesia. Ger. Pat. 302,836. See VIII.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Ironsand; Smelting of New Zealand —. J. E. L. Cull. New Zealand J. Sci. Tech., 1918, 1, 43–48.

THE ordinary blast-furnace process is inapplicable to the black ironsand found on the west coast of South Island owing to the physical condition of the ore. Small-scale attempts were made to reduce the ore, after magnetic concentration, by means of a coal dust flame. They were not successful owing to the readiness with which the spongy metallic iron produced was re-oxidised. More success was achieved when the mixed ore and coal dust was fed gradually into a chamber heated by a coal dust flame. When reduction was judged complete the charge was dropped into an electric arc furnace, limestone and fluorspar were added, and the whole was brought to fusion to permit of separation of metal and slag.—H. J. H.

Malleable cast iron; Influence of silicon and of the duration of annealing on the mechanical and physical properties of —. E. Leuenberger. Stahl u. Eisen, 1917, 37, 513–521, 601–609. Z. angew. Chem., 1918, 31, Ref., 115.

THE effect of impurities on malleable cast iron is much more marked than on grey cast iron, and the composition can only be altered within narrow limits. The effect of such impurities may be very much greater upon the course of the conversion into malleable iron than upon the casting properties or strength of the material. The lower the silicon content (below 0.65%) the more complete is the decarburisation. Silicon has no effect on the tensile strength. With increasing silicon the hardness increases slightly, while the elongation, reduction of area, and impact values decrease, especially with the more drastic annealing. Increasing the duration of refining lowers the strength and hardness, and raises the ductility and impact test. The specific volume of the annealed material is raised about 0.01 by 1% Si, and further annealing produces little further change. Low-silicon iron shows a

diminution in volume as a result of conversion into malleable iron, while a high silicon content produces an increase of volume. As the duration of annealing increases the limit between the positive and negative volume changes rises from 0.55 to 0.70% Si. The specific electrical resistance of the malleable iron is raised about 20 microhms per cm. cube by 1% Si and that of the untreated iron by 32. Silicon has little effect on the annealing within the limits in which it is usually present, but an increase of silicon content and of the period of annealing produces a product of coarser grain. Although increase in the time of annealing lowers the strength of the malleable iron, yet a long period is advantageous since the toughness is appreciably increased, and for malleable iron of the greatest toughness and ductility a low silicon content and long refining are required.—F. C. TH.

Zinc; Electrodeposition of —. C. A. Hansen. Trans. Amer. Inst. Mining Eng., 1918. Met. and Chem. Eng., 1918, 18, 481—482.

THE reactions involved include the deposition of zinc at the cathode according to the usual electrochemical theory, and re-solution of this deposited zinc, depending on the surface exposed and the acidity of the solution, the difference between perfect efficiency and the actual being a measure of this corrosion. An increased efficiency is attained by removing the unsatisfactory solution, and by reducing the current and the concentration of the acid, as well as by the use of organic reagents such as glue or lanolin. High current densities are found to yield rougher deposits, especially with low acid concentrations. Of the impurities present in the electrolyte copper and cadmium are precipitated with the zinc, whilst arsenic and antimony remain in solution. Manganese by itself exerts no harmful effect. Of the cumulative impurities the alkali metals and magnesium are unimportant, but even the smallest traces of nickel, cobalt, vanadium, and uranium act injuriously. Pure solutions yield excellent deposits; pinholes are almost always found when impurities are present. No inorganic addition has been found appreciably to improve the cell.—F. C. TH.

Copper-zinc alloys; Influence of cadmium on the properties of —. L. Guillet. Comptes rend., 1918, 166, 735—737.

Two series of alloys containing respectively 60% and 70% Cu and from 0 to 4% Cd have been studied as to their mechanical properties and microstructure. Cadmium has no effect on the mechanical properties of brasses with 70 or 60% Cu unless the cadmium content exceeds 1%. Its influence is first noted in a clearly marked lowering of the resilience. The elongation, under traction, only diminishes when the cadmium content reaches 2%. The modifications of the mechanical properties coincide with the appearance of free cadmium as a structural constituent; this at first forms a marked film round the metallic grains, and then when the cadmium content reaches 2%, separates in round grains. The injurious rôle of cadmium is more marked in α -brasses than in those composed of α and β solid solutions.—W. G.

Patina; An artificial —. O. Grotian. Z. Elektrochem., 1918, 23, 83.

AN incrustation or patina on copper articles similar to that found on ancient bronzes can be produced by electrolysis of a solution of copper sulphate between copper electrodes for three minutes with a current density of 1 amp. per sq. dm.; the current is then interrupted and the cathode removed

from the liquid. The anode is allowed to remain undisturbed in the liquid for 24 hours. The process is then repeated, alternately passing the current for 3 minutes and leaving the anode for 24 hours. After several repetitions the anode is found to be covered with a beautiful bluish-green non-crystalline patina, which cannot be removed by washing. The film has the composition $\text{CuO} \cdot 3\text{H}_2\text{O}$. (See also J. Chem. Soc., June 1918.)—J. F. S.

Flotation versus cyaniding [of gold and silver ores]. G. H. Clevenger. Eng. and Min. J., 1918, 105, 743—746.

FLOTATION has not been so successful in the treatment of gold and silver as in that of base metal ores because, whilst mechanical concentration of the latter was imperfect, the cyanide process had reached a high degree of efficiency. Hence flotation increased the extraction of base metals without involving a change in smelting methods; on the other hand, flotation in the case of precious metal ores produces only a concentrate, not bullion, as does the cyanide process. Further, the extraction by cyanide in the majority of cases cannot be improved upon. As regards cost of treatment, flotation is generally cheaper than cyaniding, although the cost of marketing the concentrate is often high. With ores containing base and precious metals, flotation may either remove metals interfering with cyaniding or, if gold and silver accompany the other values into the froth, render cyaniding superfluous. Flotation has been introduced at Cobalt, and in California for the treatment of amalgamation tailings from the Mother Lode; it was tried and abandoned at Tonopah and Goldfield (Nevada), and at Cripple Creek (Colorado).—W. R. S.

Flotation in relation to gangue minerals. J. M. McClave. Eng. and Min. J., 1918, 105, 738—739.

CASES of failure have occurred which prove the necessity of carefully studying the gangue minerals of an ore before designing a flotation plant. Ore from different parts of the same mine, although containing the same metalliferous minerals, may require different flotation treatment if the nature of the gangue is different; this has also been proved on synthetic ore mixtures. Presence or absence of calcite, or variation in its quantity, has been known to change the course of flotation. In another instance a small amount of rhodochrosite appearing in the gangue of a silver-lead ore made flotation with the usual oil mixture impossible. Failure to produce a good froth with a zinc-lead-copper ore after successful small-scale tests was traced to the presence of epidote.—W. R. S.

Flotation; Troubles in —. O. C. Ralston. Eng. and Min. J., 1918, 105, 735—737. (See also this J., 1918, 12 A.)

ACCIDENTAL over-oiling and addition of too much electrolyte where such is used are among the most common causes of irregular working in ore flotation processes. At the Ohio Copper Co.'s mill, where mine water containing iron and copper sulphate is used, satisfactory extraction seemed impossible until a very small amount of cyanide was added to the pulp; the beneficial effect must be ascribed to the formation of complex cyanides, as free potassium cyanide is known to be detrimental to flotation. Lubricating oil dripping off bearings, organic matter in swampy water, glue, variability in different shipments of oil or in the water supply (e.g., after heavy rain), fluctuation in the feed, soluble matter from recently-set cement, have all been found to disturb the work of flotation plants. Sizing the ore previous to flotation is harmful, and an unsized mixture almost invariably gives the best results.—W. R. S.

PATENTS.

Spiegel; Manufacture of —. A. L. Cromlish, Sharon, Pa. U.S. Pat. 1,251,907, Apr. 9, 1918. Date of appl., Jan. 27, 1917.

In a process for the recovery of manganese from "flush cinder," a mixture of the latter with coke and tap cinder is heated in a blast furnace to produce a spiegel of low manganese and high phosphorus content.—W. E. F. P.

Zirconium ores; Process of purifying —. W. R. Loveman, Lakewood, Ohio, Assignor to National Carbon Co., Inc. U.S. Pat. 1,251,918, Apr. 9, 1918. Date of appl., Aug. 18, 1915.

The ore is crushed, fused "with sodium carbonate in a ratio greater than 1 to 6," and the soluble salts washed out from the fused mass. The residue is treated with dilute hydrochloric acid and then calcined.—T. H. B.

Aluminium-alloy articles; Method of making —. A. Wilm, Schlachtensee-Berlin, Germany. U.S. Pat. 1,251,987, Apr. 9, 1918. Date of appl., May 24, 1912. Renewed Aug. 23, 1917.

The articles are formed from an alloy produced by the addition of about 0.5% of magnesium to a molten mixture of aluminium, copper, and manganese, containing from 3 to 6% of copper, and manganese equivalent to one-seventh of the copper. They are then heated to somewhat below the congealing point of the alloy (above 420° C.) "until uniform proportional distribution of the metals is attained throughout the mass," and finally cooled at such a rate as to ensure fixation of this condition.—W. E. F. P.

Aluminium skimmings and analogous material; Method of utilising —. *Process of treating aluminium skimmings, screenings, etc.* J. W. Lawrie, Assignor to W. F. Jobbins, Inc., Aurora, Ill. U.S. Pats. (A) 1,262,062 and (B) 1,262,063, Apr. 9, 1918. Dates of appl., Apr. 8, 1913, and Aug. 1, 1914.

(A) SKIMMINGS, slags, dross, or similar waste aluminous materials are treated with a solution of caustic alkali, and after separating zinc, copper, iron, etc., as sulphides, pure alumina is precipitated and separated from the aluminate solution. (B) After removal of larger pieces of free aluminium or alloys the material is boiled with water under pressure to decompose nitrides and carbides, and oxidise the remaining free metal. The residual solids are treated with dilute acid to remove the bulk of the iron, the residue is treated with strong acid to produce a solution of an aluminium salt, from which any copper is precipitated, and the purified aluminium salt solution evaporated.—T. H. B.

Shaft for roasting furnaces. D. Balrd, Berkeley, Cal., Assignor to General Chemical Co., New York. U.S. Pat. 1,262,432, Apr. 9, 1918. Date of appl., July 3, 1915.

A hollow shaft, divided into two parallel and continuous chambers of unequal cross-section by a longitudinal partition, and having a number of sets of rabble-arm inlet and outlet ports spaced longitudinally. The ports of a given set are angularly disposed in the same horizontal plane, and the ports of the different sets are separated by opposite edges of the partition.—W. E. F. P.

Volatilising ores; Process of —. S. I. Clawson, Salt Lake City, Utah. U.S. Pats. (A) 1,262,452 and (B) 1,262,453, Apr. 9, 1918. Dates of appl., Aug. 4 and 11, 1909.

(A) The ore is preheated by direct treatment with fire-box gases to a temperature below the volatilisa-

tion point of metal chlorides, and fumes and gases are allowed to escape. While the ore is still hot it is treated with a halogen reagent, and the halogen compounds volatilised into a fume arrester. (B) The pulverised ore is heated and treated with chlorine, and the fumes containing chlorides of the metals are passed into an aqueous acid solution, from which the chlorine is subsequently separated by electrolysis to be used again in the process.

—T. H. B.

Magnesium; Apparatus for the electrolytic preparation of —. Allgem. deutsches Metallwerk, G.m.b.H., Berlin-Oberschönewalde. Ger. Pat. 302,024, Mar. 3, 1915.

The cover of the electrolytic vessel is provided with a removable bell dipping below the surface of the molten electrolyte. The cathode passes through the bell and can be lowered, raised, or removed at will. The molten magnesium as it forms around the cathode rises into the bell, in which it solidifies, and can be removed with it, dove-tail shaped grooves in the underside of the top of the bell assisting in holding the solidified metal in place.

—B. V. S.

Pickling iron and steel plates and the like; Machines for —. J. Paton, Pontypool. Eng. Pat. 115,111. (Appl. Nos. 6765, May 12, and 13,647, Sept. 22, 1917.)

Screening plant for dealing with metalliferous ores and other substances. R. F. and H. S. Pochin, Leicester. Eng. Pat. 115,065, Apr. 20, 1917. (Appl. No. 5549 of 1917.)

Metal briquettes; Apparatus for use in the production of —. Campbells and Hunter, Ltd., and C. Korte, Leeds. Eng. Pat. 115,258, Apr. 28, 1917. (Appl. No. 6011 of 1917.)

Buddles for concentrating tin and other ores. A. Richards, Redruth. Eng. Pat. 115,377, Nov. 15, 1917. (Appl. No. 16,761 of 1917.)

Blast furnaces and the like; Charging apparatus for —. A. Sahlin, London. Eng. Pat. 115,405, Mar. 20, 1918. (Appl. No. 4953 of 1918.)

Process for treating sulphurous fumes. U.S. Pat. 1,262,295. See VII.

XI.—ELECTRO-CHEMISTRY.

PATENTS.

Voltaic cell. M. E. Conrad, Atlantic, Iowa, Assignor to C. B. Schoenmehl, Waterbury, Conn. U.S. Pats. (A) 1,262,019 and (B) 1,262,020, Apr. 9, 1918. Date of appl., Feb. 7, 1917.

A NEGATIVE electrode is composed of (A) oxy-arsenide or (B) oxy-phosphide of iron.—B. N.

Separator; Storage battery —. W. Morrison, Chicago, Ill. U.S. Pat. 1,262,228, Apr. 9, 1918. Date of appl., Feb. 20, 1918.

The separator is composed of porous non-ligneous material, such as asbestos, impregnated with barium sulphate.—B. N.

Electrolytic apparatus. J. B. Herreshoff, jun., Richmond Hill, N.Y. U.S. Pat. 1,262,045, Apr. 9, 1918. Date of appl., Dec. 4, 1915.

SEVERAL bi-polar electrodes are supported in an electrolytic cell by means of lugs projecting later-

ally at the top of each electrode, and off-set in relation to the centre of the electrode. Suitable supports are arranged for each lug, whereby when the electrodes are assembled in the cell or tank a vertical line will pass through the supports and the centre of gravity of the electrode. The electrodes are thus supported in an inclined position at such an angle that impurities or slime will not adhere to either the cathode or anode surfaces, and succeeding electrodes are substantially parallel.—B. N.

[*Electric*] induction furnaces. The Ajax Metal Co., Assignees of J. R. Wyatt, Philadelphia, U.S.A. Eng. Pat. 103,645, Dec. 22, 1916. (Appl. No. 18,388 of 1916.) Under Int. Conv., Jan. 24, 1916.

SEE U.S. Pat. 1,201,671 of 1916; this J., 1916, 1236.

Electrical apparatus for heating stills, boilers, and the like. U.S. Pat. 1,262,072. See 11b.

Process for the regeneration of tin chloride solution. Ger. Pat. 302,040. See VII.

Process for the electrolytic oxidation of acid chromic liquors to chromic acid. Ger. Pat. 303,165. See VII.

XII.—FATS; OILS; WAXES.

Determination of fatty acids in butter fat. Holland and Buckley. See XIXa.

PATENTS.

Hydrogenating resistant [acid] fatty material for edible purposes. C. Ellis, Montclair, N.J. U.S. Pat. 1,261,911, Apr. 9, 1918. Date of appl., Jan. 9, 1915.

STRONGLY acid fatty material is heated with a compound of high boiling point containing an esterifying hydroxyl group, e.g., glycerin, at a temperature above 250° C. in presence of hydrogen, until the acid value of the material is reduced to a relatively low point, a hydrogenating catalyst is added, the temperature reduced, and the contact with hydrogen continued until the material is hydrogenated to the desired degree.—A. de W.

Fat; Process for the recovery of — from raw materials and by-products. P. Lindner, Charlottenburg. Ger. Pat. 302,692, Feb. 19, 1914.

LIVING organisms are added to suitable decaying and waste material which is thereby converted in part into living fatty matter, and after a time the organisms are killed and the fat extracted by a suitable process.—L. A. C.

Glycerin; Process for the purification of crude —. Vereinigte Chem. Werke A.-G., Charlottenburg. Ger. Pat. 302,826, Aug. 19, 1915.

The glycerin is combined, in the absence of water, and if necessary in the presence of a condensing agent, with an organic acid of which the glyceryl ester is insoluble in water. The ester is purified, hydrolysed, and the glycerin solution concentrated or distilled, if necessary in a vacuum.—L. A. C.

Apparatus for cleansing and filtering oil and similar liquids. Eng. Pat. 115,140. See I.

Manufacture of foodstuffs [from oil-cakes]. U.S. Pat. 1,260,656. See XIXa.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

PATENTS.

Lithopone; Method of rendering — light-proof. Light-proof lithopone and process of making same. G. Rigg, Palmerton, Pa., Assignor to the New Jersey Zinc Co., New York. U.S. Pats. (A) 1,260,811 and (B) 1,260,812, Mar. 26, 1918. Date of appl., Apr. 28, 1916.

(A) LITHOPONE is rendered light-resistant by decomposing the zinc sulphate therein into products unaffected by light, e.g., by grinding the lithopone with barium nitrate so as to convert the zinc sulphate into zinc nitrate and barium sulphate. (B) After removal of soluble constituents the calcined lithopone is treated with barium sulphide to convert the remaining zinc sulphate into zinc sulphide.—C. A. M.

Resins; Method of separating — from impurities. J. S. MacLaurin, Wellington, New Zealand. U.S. Pat. 1,260,984, Mar. 26, 1918. Date of appl., Dec. 19, 1917.

RESIN containing heavier impurities is agitated for 15 to 60 mins., in a partially exhausted vessel, with an aqueous solution of salt, the sp. gr. of which is greater than that of the resin, but less than that of the impurities. Air is then admitted and the agitation continued for 2 to 3 mins., after which a vacuum is again created, and the agitation renewed. After settling, the resin is withdrawn from the upper part of the mass and washed free from salt.—C. A. M.

Oil varnish and process of making same. O. Boecking, Hamburg, Germany. U.S. Pat. 1,262,302, Apr. 9, 1918. Date of appl., July 6, 1914.

AN oil varnish is prepared by heating together copal resin, fatty oil, and sulphur to form a homogeneous mixture, and then heating at an increased temperature to form a varnish.—A. de W.

Benzol varnishes. S. Langguth, Dortmund. Ger. Pat. 302,741, Sept. 26, 1916.

SO-CALLED naphthol-pitch, i.e., the condensation product formed in the preparation of α - and β -naphthol, is extracted with benzol or alcohol, whereby a resin is extracted which is insoluble in soda, soluble in benzol and alcohol, and gives waterproof coatings.—A. de W.

Shellac substitute [; Naphthol-resin as —]. S. Langguth, Dortmund. Ger. Pat. 302,742, Apr. 7, 1916.

THE resinous condensation products formed in the manufacture of α - and β -naphthols are extracted with alcohol, and the residue from the evaporation of the same is utilised as a shellac substitute.—A. de W.

Varnish; Process for the preparation of —. J. Fluss and J. Tanne, Vienna. Ger. Pat. 302,825, Nov. 25, 1916.

RESINS of the Olibanum species are subjected to dry distillation to free them from their accompanying ethereal oils. The residue is extracted with solvents of low boiling-point, e.g., dichloroethylene, whereby the resinous substances only are removed. The residue may be further extracted with a solvent of higher boiling-point. The resinous constituents are in this way freed from injurious impurities, and yield a hard, quick-drying varnish of a high

degree of gloss, transparency, and resistance to weather and water.—A. de W.

Litharge cement; Preparation of a —. Th. Goldschmidt A.-G., Essen. Ger. Pat. 302,852, Apr. 15, 1917.

An improvement on the ordinary litharge-glycerol cement is obtained by using glycol in place of glycerol. A mixture of 75% of litharge and 25% of glycol yields a product which hardens in 1–2 hours, whilst a mixture of 90% of litharge and 10% of glycol sets still more quickly.—A. de W.

Process of drying varnished surfaces. U.S. Pat. 1,262,977. See XV.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber; Chemical and mechanical-technical examination of —. J. G. Fol. Gummi-Zeit., 1917, 31, 761. Z. angew. Chem., 1918, 31, Ref., 45.

In order to form a correct judgment on the quality of rubber it is necessary, in addition to making chemical analysis and vulcanisation tests, to ascertain whether the various original constituents of the rubber and any substances which have been subsequently incorporated in it, remain in the same relative proportions and can be rediscovered by chemical analysis. Preliminary experiments have led to the following conclusions:—The resin content remains practically constant throughout the various operations, although a slight decrease may sometimes be observed after vulcanisation. The proportion of insoluble constituents is decreased by mechanical working. The protein matter is not quantitatively precipitated by the petroleum method applied for the separation of insoluble substances. When free sulphur is present to the extent of several units per cent., it cannot be oxidised quantitatively by nitric acid. The estimation of fillers by boiling with petroleum yielded with the mixture investigated (rubber 50, zinc oxide 62, magnesia 13, sulphur 5) low results, as also did the determination of the ash. The viscosity of the rubber is diminished by mechanical working on the washing rolls, and still more by working on hot rolls; this is attributed to a reduction in the molecular complexity. The indirect method for the estimation of rubber in a vulcanised product gives results which deviate several units per cent. from the quantity of rubber actually used.—D. F. T.

Rubber; Estimation of the content of unsaponifiable resins in various kinds of —. P. Dekker. Gummi-Zeit., 1917, 31, 824. Z. angew. Chem., 1917, 31, Ref., 46.

When the mineral oil in a rubber mixing is estimated by the measurement of the unsaponifiable portion of the acetone extract which is soluble in petroleum ether, the accuracy of the result is affected by the fact that a part of the rubber resins resists saponification and is included with the mineral oil. The oxidation products of rubber are completely saponifiable, and the ordinary method of analysis includes them with the saponifiable resins.—D. F. T.

Balata and gutta percha; Estimation of resin and impurity in —. P. Dekker. Gummi-Zeit., 1917, 31, 824. Z. angew. Chem., 1917, 31, Ref., 46.

ACETONE is the most trustworthy solvent for the extraction of balata and gutta percha. Ether dissolves a part of the gutta or balata and so gives

high results, whilst with alcohol the gutta becomes plastic on account of the higher boiling point of the solvent, and the extraction is thereby rendered incomplete. When balata is extracted with alcohol a portion of the material insoluble in xylene passes into solution and is included with the resinous matter.—D. F. T.

Rubber; Depolymerisation of raw —. A. van Rossem. Gummi-Zeit., 1917, 31, 851. Z. angew. Chem., 1918, 31, Ref., 46.

When rubber is heated for 6 hours at 130° C. in a sealed glass tube containing air, it melts to a brown syrup, whereas this change is not observed in a vacuum or in hydrogen, nitrogen, or carbon dioxide. With 1% rubber solutions in xylene, oxidation does not set in until after several hours, commencing first when a certain limit of relative viscosity has been passed. Depolymerisation occurs much more rapidly in the presence of oxygen than in other gases, oxygen appearing to exert a catalytic effect; the rate of depolymerisation depends also on the nature of the solution. (See also this J., 1917, 1242.)—D. F. T.

PATENT.

Vulcanised rubber (soft rubber, ebonite, etc.); Regeneration of —. B. J. F. Varenhorst, The Hague, and J. G. Fol, Dell, Netherland Indies. Ger. Pat. 302,995, Mar. 19, 1914.

VULCANISED rubber is heated to a high temperature, without melting, in a vacuum or in an inert gas, and the harmful effect of the air on heated rubber is avoided by rapid cooling, e.g., by treatment with cold water, or solutions of sodium carbonate or alkali.—D. F. T.

XV.—LEATHER; BONE; HORN; GLUE.

Skins; Conservation of — by desiccation. E. Nihoul. J. Soc. Leather Trades' Chem., 1918, 2, 2–16.

SKINS should be dried whilst raised well above the ground so as to expose both sides to draughts of air, and ground covered with vegetation should be avoided, as it is necessarily cool and damp. If skins are thus dried immediately after flaying, putrefaction should not occur. The sun's light may cause some chemical decomposition, and certainly inhibits bacterial activity. The heat of the sun's rays is not only fatal to many bacteria, but causes coagulation and hardening of the tissues, especially on the surface, and thus further limits bacterial activity. Surface hardening prevents the rapid escape of moisture from the interior. The author, however, does not think that the moist interior will gelatinise at the temperatures reached if ammonia is absent.—F. C. T.

Tannin colloids; Fermentation of vegetable —. W. Moeller. Collegium, 1917, 49–55. Z. angew. Chem., 1918, 31, Ref., 7.

TANNINS, like polyhydric phenols, are converted by certain enzymes (polyphenoloxidases) into humic acids, a change involving simultaneous oxidation and condensation with considerable loss of tanning power. As such fermentation may occur at any time during the storing or use of extracts, tanners should ascertain to what extent formation of humous matter has taken place, and should reject extracts in which the fermentation has been considerable. Phenol, thymol, toluol, and other substances inhibit or entirely prevent the process.

—F. C. T.

Tannins; Detection of — by the formaldehyde precipitation method. R. Lauffmann. *Collegium*, 1917, 322.

THE precipitates obtained by the Stiasny formaldehyde test (this J., 1906, 275) for tannins were weighed in an attempt to obtain characteristic figures for different tannins. The results are given in the following table:—

	% of total soluble matter precipitated.	% of tannin precipitated.
Pine bark	59-65	92-99
" " extract	40-49	66-80
Oak bark	61-80	82-101
" " extract	42-62	64-89
Oak wood	20-30	26-36
" " extract	12-19	17-26
Quebracho extract ..	94-96	105-107
4 parts oak bark ext. 1 part queb. ext. ...	62 (calc. 55)	82 (calc. 74)

The variations found were disappointingly large.
—F. C. T.

Tanning materials, extracts, chrome liquors, and leather; Critical examination of —. R. Lauffmann. *Collegium*, 1917, 377 and 401. J. Soc. Leather Trades' Chem., 1918, 2, 58 and 150-151.

THE value of tannins does not depend simply on the percentage of tannin, but on the ratio of tannins to non-tannins, and on the degree of clarification and decolorisation. Badly clarified extracts show a high content of insoluble matter on analysis, and liquors made from them should be cleared by settling before use, or slow tannage and an inferior leather will result. The best practical test for insoluble matter is that of Paessler and Kelt, in which 20 c.c. of extract is diluted with 80 c.c. of water and allowed to stand overnight. The volume of the settled precipitate should be at most a few cubic centimetres and the supernatant liquor should be clear. Sulphites in extracts should be determined by expelling sulphur dioxide and determining sulphates in the residue, and then oxidising the sulphites in the extract and redetermining sulphates. The difference between the two estimations gives sulphites as sulphuric acid. The physical properties of leather deserve consideration. A brittle grain may be due to too great excess of tannin or filling materials, damage to fibres by heat, use of too strong alkalis in liming, or to mineral acid. Paessler's method of detecting free sulphuric acid consists in dialysing 10 grms. of the leather before and after heating at a low temperature *in vacuo* to expel volatile acid. The outer water of the dialyser should be coloured with Congo-red which will indicate diffused acid. If no sulphates are present in the dialysate, free sulphuric acid is absent. If the second dialysate is acid but free from sulphates, non-volatile organic acids (lactic and oxalic) should be sought. There is no means of detecting free sulphuric acid in the presence of non-volatile organic acids. The permeability of leather to water should be tested.

—F. C. T.

Salt stains [on leather]; Theory of the cause of —. W. Moeller. *Collegium*, 1917, 7-14, 55-59, 105-124, and 153-161. *Z. angew. Chem.*, 1918, 31, Ref., 8.

A "PHYSIOLOGICAL" tanning process in either the living or dead organism is regarded as the cause of salt stains. Various substances may act as tanning agents, *e.g.*, iron or sulphur, melanines, or sulphur and iron bacteria. The stains are due to very small quantities of the active substances. The most important preventive is the use of some

alkali as a preserving or curing agent. The tanning cannot take place in the presence of alkali.

—F. C. T.

Leather; Analysis of vegetable sole —. J. Soc. Leather Trades' Chem., 1918, 2, 51-54 and 82-87.

THE following methods have been agreed upon by the leading English leather trade chemists. Moisture is determined before and after drying, and all results in the analysis are calculated on a standard basis of 14% of moisture. In determining total ash, the charred mass is washed with water if soluble salts are present which hinder the incineration. The residue is ignited at a low red heat, and the solution added and evaporated and the whole gently ignited. Water-soluble matter is extracted by continuous percolation in a Procter extractor. The rate of flow should be about 5.5 c.c. per minute. Only potassium (or sodium) sulphate is to be added to the sulphuric acid in the digestion for the determination of nitrogen. 20 c.c. of sulphuric acid should be used for not more than 1 grm. of leather. A blank test of the reagents should be made with sugar. In the determination of glucose, a little sodium carbonate (about 0.1 grm.) should be used to remove the last trace of lead after the bulk has been removed by sodium sulphate. After heating the solution with hydrochloric acid, reducing sugars are determined by the official method of the American Leather Chemists' Association.—F. C. T.

Sodium sulphate in leather. T. Mann. J. Soc. Leather Trades' Chem., 1918, 2, 19-23.

THE usual method of determining sodium sulphate in leather by estimating the total SO₄ in the leather ash, deducting the amount corresponding to the magnesium present, and calculating the remainder as sodium sulphate, leads to quite erroneous results, as the whole of the sulphur present in any form in the leather is returned as magnesium or sodium sulphate. It is preferable to determine the soda present in the leather, since any sodium salt is just as objectionable as the sulphate. 5.5 grms. of leather is incinerated in a platinum dish at a low red heat and the residue weighed. 11 grms. may be used if the ash is very low. 1 c.c. of N/1 sulphuric acid is added for every centigram of ash, the mixture digested over a low flame till the residue is almost dissolved, the water evaporated as far as possible, and the sulphuric acid then fumed off. The residue is ignited and weighed, and then dissolved in 10 c.c. of strong hydrochloric acid by gentle boiling. The solution is filtered into a 110 c.c. flask and made up to the mark. The residue on the filter is silica, and, if barium is present, barium sulphate. 50 c.c. of the filtrate is measured into each of two beakers. The solution in one is made neutral to methyl orange with strong ammonia, then made faintly acid, and a further 15 drops of concentrated hydrochloric acid added. The solution is boiled, 10 c.c. of 7.62% barium chloride solution added, and the whole allowed to digest on the hot plate for half an hour. The precipitate of barium sulphate is filtered off and weighed next day. A quarter of a 7 cm. filter is torn to pieces, shaken to pulp with 5 c.c. of strong hydrochloric acid, and added to the second 50 c.c. of original solution. Strong ammonia is then added until there is a distinct smell of the reagent, the solution boiled and filtered, and the precipitate weighed as ferric oxide and alumina, etc. To the filtrate, 5 c.c. of 2.5% ammonium oxalate solution is added, the mixture boiled, allowed to stand on the hot plate, and filtered. The precipitate is ignited and weighed as calcium oxide. Magnesium is precipitated from the solution by slightly acidifying, adding 10 c.c. or more

of 8.95% sodium phosphate solution, cooling, and making just alkaline with ammonia. After the mixture has stood for half an hour, 25 c.c. of strong ammonia is added and the solution left overnight. The precipitate is washed with dilute ammonia and weighed as magnesium pyrophosphate. From the above determinations the amount of soda is calculated. The percentages of silica, ferric oxide, lime, magnesia, and SO_2 are added, and the total deducted from the percentage of sulphated ash. The difference is sodium oxide (Na_2O) and is calculated as sodium sulphate. The procedure is slightly modified if barium is present. It is not satisfactory to precipitate silica, iron, and lime together.—F. C. T.

Water-soluble matter in leather; Extractor for —. L. Balderston and W. K. Alsop. J. Amer. Leather Chem. Assoc., 1918, 13, 142–144.

AN extractor is described and illustrated which allows of the maintenance of a constant temperature, the covering of the sample with water throughout the extraction, easy regulation of the flow of water, independent water supply for each sample, easy washing of all parts, and convenient weighing of sample after extraction. The leather is extracted in an aluminum thimble, which fits loosely in a copper cylinder passing through and soldered to a copper vessel in which water is maintained at a constant temperature. The water for percolation flows into the copper cylinder from an inverted copper flask, and the rate of flow is regulated by a screw-cock at the bottom of the cylinder.—F. C. T.

Fat; Determination of — in leather. J. A. Wilson and E. J. Kern. J. Amer. Leather Chem. Assoc., 1918, 13, 138–141.

A Mixture of equal parts of ether and carbon tetrachloride is the best solvent for fat extraction. It dissolves the fats more completely than petroleum spirit, is not readily inflammable like pure ether, and is not liable to attack the leather by reason of a high boiling point, as is pure carbon tetrachloride. Levi and Orthmann's method (J. Amer. Leather Chem. Assoc., 1915, 10, 445), which consists in shaking the finely divided leather with petroleum spirit, allowing to stand for 24–72 hours, and subsequently evaporating an aliquot part of the solution, gives in general too low results.—F. C. T.

Leather; [Determination of] moisture in —. C. D. Wilkinson. J. Soc. Leather Trades' Chem., 1918, 2, 132–133.

Two hours' drying of powdered leather in a vacuum of 60 mm. of mercury at 98° – 100° C. is not sufficient. Results are much worse at about 250 mm.—F. C. T.

Chromium; Estimation of — in chrome salts, liquors, leather ashes, and residues. K. Schorlemmer. Collegium, 1917, 345 and 371. J. Soc. Leather Trades' Chem., 1918, 2, 57–58.

Chromium determinations should always be made volumetrically, the gravimetric method being invariably inaccurate owing to the occlusion of alkali salts by the chromium hydroxide, and subsequent production of chromate on ignition. Chrome salts are best oxidised by means of alkali and hydrogen peroxide. The chromate produced is most accurately and rapidly determined by the potassium iodide method. Chromium in leather ashes is oxidised by fusion with magnesia and sodium carbonate. Chrome liquors containing organic matter cannot be oxidised by peroxide solutions, but require strong alkaline permanganate,

which is added at intervals until the colour persists on boiling. The excess is removed by adding alcohol, drop by drop, whilst boiling. If iron is present in chromate solutions, it will be determined as chromium by the potassium iodide method. It is best to free the solution from iron and re-determine the chromium. The titration of the chromate solution with ferrous ammonium sulphate should give a correct result, but apparently does not always do so.—F. C. T.

Lactic acid; Economy of — [in leather manufacture]. H. R. Procter. J. Soc. Leather Trades' Chem., 1918, 2, 121–122.

Formic and oxalic acids are efficient substitutes for lactic acid. Boric and sulphurous acids are sufficiently weak to be used with safety, and the latter is very cheap when made by burning sulphur. If organic acids are used in deliming, they should be regenerated in the used liquor by the addition of sulphuric acid. If the calculated quantity of organic acid is first used, afterwards $\frac{1}{4}$ of that amount may be added together with $\frac{3}{4}$ of the equivalent of sulphuric acid. This may be repeated until the liquor is too foul to use. Formic or oxalic acid is better than mineral acid for adjusting the acidity of tan liquors.—F. C. T.

Lactic acid; Determination of lactic anhydride in —. F. C. Thompson and K. Suzuki. J. Soc. Leather Trades' Chem., 1918, 2, 115–121.

Pure lactide was prepared and found to react completely with alkali (including calcium hydroxide) in the cold in ten minutes, if the alkali used was twice the equivalent of the lactide present. Consequently heating with excess of alkali in the analysis of lactic acid is unnecessary, and should a method involving heating show a higher content of lactide than a method using the reaction in the cold, the excess is due to compounds other than lactide which are capable of reacting with alkali. Lactide will effectively remove lime from lined skins. Water slowly converts lactide into lactic acid, the greatest change occurring with the greatest dilution. Consequently determinations of lactide are valueless when lactic acid is to be subsequently used in dilute solution.—F. C. T.

Lactic acid; Estimation of iron in —. A. Harvey. J. Soc. Leather Trades' Chem., 1918, 2, 37–38.

Iron in lactic acid can be estimated with great accuracy by a colorimetric method. Potassium ferrocyanide is used as indicator, and the colour developed by a definite quantity of dilute lactic acid is matched by the colour due to a standard iron solution. Potassium thiocyanate is quite useless as indicator.—F. C. T.

PATENTS.

Varnished surfaces [patent leather]; Process of drying —. G. W. Priest, Newton, Mass. U.S. Pat. 1,262,977, Apr. 16, 1918. Date of appl., June 10, 1911.

The varnished surface of patent leather is finished by exposure to light rich in ultra-violet rays, and may be simultaneously exposed to the action of a heated atmosphere.—F. C. T.

Leather substitute. Deutsche Gasglühlicht A.-G. (Aueres.), Berlin. Ger. Pat. 302,329, Jan. 14, 1914. Addition to Ger. Pat. 256,407 (this J., 1913, 438).

Especially good results are obtainable by submitting the skins repeatedly to successive treatments

in two baths, one containing a solution of a mineral salt such as lead acetate, barium chloride, zinc sulphate, or aluminium sulphate, and the other containing sulphuric acid or a solution of sodium sulphate or carbonate. An additional advantage is that the tanned skins need less glycerin to render them pliable.—D. F. T.

Leather; Production of sheet — from leather waste. M. Rigell, Buda Pest. Ger. Pat. 302,330, July 16, 1916.

THE selected waste after treatment with an aluminium salt and vegetable tannin is dried and submitted to the action of a solution of soap; the dried material may then be soaked in a 10–14% solution of barium chloride before being passed between grooved rolls into a warm solution of an adhesive, after which it is lightly pressed and the immersion repeated in a weaker solution of adhesive, followed by greater pressure; passage through a tanning solution completes the chemical treatment, the material being finally dried.

—D. F. T.

Tanning of hides and skins. E. Hupertz, Rodenkirchen. Ger. Pat. 302,992, Apr. 29, 1916.

THE tanning of skins with phenols or formaldehyde derivatives of these is effected in the presence of quinoline, or of compounds of quinoline with thiocyanic acid or with an alkali thiocyanate; formates of magnesium, aluminium, potassium, or sodium may also be present, and further additions may be made of vegetable tanning extracts and of sulphite-cellulose waste liquor. With these modifications the ordinary process of tanning is considerably accelerated, and the characteristics of the product may resemble those of material obtained with vegetable tannin.—D. F. T.

Tanning hides and skins; Process of —. E. Hupertz, Rodenkirchen. Ger. Pat. 303,601, Jan. 31, 1917. Addition to Ger. Pat. 302,992 (see preceding abstract).

PYROLIGNEOUS acid or one of its salts is added to the tanning liquor described in the chief patent. On account of its content of wood tar, acetone, and methyl alcohol, pyroligneous acid is much more suitable for tannery purposes than is pure acetic acid, having a strong antiseptic action and an accelerating effect on tannage.—F. C. T.

[*Tanning agents.*] *Condensation products of α - or β -naphthol-monosulphonic acids and formaldehyde; Process for preparing —.* Deutsch-Koloniale Gerb- und Farbstoff-Ges., Karlsruhe-Rheinhafen. Ger. Pat. 303,640, Aug. 10, 1915.

THE products obtained by condensing 1 mol. of formaldehyde with 2 mols. of α - or β -naphthol-monosulphonic acid are further condensed with 1 mol. of formaldehyde or with the equivalent of a formaldehyde-yielding substance. New products are obtained which precipitate gelatin from solution and possess tanning properties like the original condensation products, but which are in general more easily soluble in water.—F. C. T.

Leather substitute suitable for the reproduction of models; Preparation of a —. F. Krohmer, Pforzheim-Brötzingen, and A. Schätzle, Pforzheim. Ger. Pat. 302,194, May 21, 1916.

LEATHER dust is mixed to a paste with a glue adhesive and an oil varnish, and the warm mixture used to impregnate bandages or strips of wide-meshed fabric. Before use the strips are softened in warm water and then wrapped to the desired thickness around a suitable model, e.g., for the

production of an artificial limb. When dry the hollow shape is removed from the model and may be polished.—D. F. T.

Leather substitute; Process for the manufacture of —. C. Jung-Reinhart, Aggsbach-Markt, Austria. Ger. Pat. 304,096, Dec. 3, 1916.

FIBROUS material, saturated with sulphurised oils, is mixed to a homogeneous mass with alkali caseinate, sulphur, shellac, and balata by means of mixing and rolling machinery. The product, finally obtained in sheets or plates, is of the character of leather and is suitable for soles when containing so little as 5% of balata. The quality and toughness of the material improve with increasing percentages of balata up to a maximum of 15%.

—F. C. T.

Plastic non-inflammable and odourless material [from gelatin]; Process of manufacture of a —. R. Piozey, Assignor to Piozey et Cie., Paris. U.S. Pat. 1,263,284, Apr. 16, 1918. Date of appl., Feb. 9, 1917.

SEE Eng. Pat. 106,448 of 1917; this J., 1917, 728.

XVI.—SOILS; FERTILISERS.

Nitrifying bacteria; Effect of — on the solubility of tricalcium phosphate.* W. P. Kelley. J. Agric. Res., 1918, 12, 671–683.

EXPERIMENTS were made with a light sandy loam soil containing 27 parts of soluble calcium and 17 parts of soluble phosphoric acid per million. Addition of tricalcium phosphate increased both values to a small extent, whilst addition of ammonium sulphate raised the proportion of soluble calcium at once to 90 parts per million. Added ammonium sulphate underwent fairly rapid nitrification, associated with an increase in the proportion of soluble calcium to more than 200 parts per million. Nitrification of ammonium sulphate, in presence of added calcium carbonate, did not increase the solubility of the soil phosphates or added tricalcium phosphate, but in absence of calcium carbonate 0.156 lb. of phosphorus was rendered soluble for every pound of nitrogen oxidised. This proportion is much less than that observed by Hopkins and Whiting in solution cultures of nitrifying bacteria containing ammonium sulphate and tricalcium phosphate; they found that in consequence of the acidity produced by nitrification 2 lb. of phosphorus was dissolved per lb. of nitrogen oxidised to nitrite. In soils the acid formed seems to decompose calcium carbonate in preference to tricalcium phosphate. From these and other experiments the author concludes that the nitrification of organic forms of nitrogen (e.g., dried blood) does not increase the solubility of rock phosphate under field conditions that are favourable to crop growth. It is possible, however, for the nitrification of ammonium sulphate to result in the solution of small amounts of tricalcium phosphate in soil of low carbonate-content.—J. H. L.

Fertiliser; Comparison of ammonium nitrate with ammonium sulphate as a —. T. Schloosing, fils. Comptes rend., 1918, 166, 714–718.

FOR trials were carried out comparing ammonium nitrate with ammonium sulphate as a nitrogenous fertiliser, maize being the crop grown. The results of the somewhat limited trial indicate that a given weight of ammonium nitrate produces the same

increase in crop as a weight of ammonium sulphate containing the same amount of nitrogen. In a discussion on field trials the author advocates the use of plots of such a size that any given operation can be performed by one person in one day on the whole series of plots.—W. G.

Animal urine; Conservation and transformation of nitrogen in —. A. Pickarski. *Z. Spiritus-Ind.*, 1917, 40, 351. *Z. angew. Chem.*, 1918, 31, Ref., 58.

Loss of nitrogen increases as water evaporates from the urine, but the loss is negligible if the liquid is kept in closed containers. Up to 90% of the urea nitrogen may be converted into ammonia; dilution with water decreases the loss of nitrogen, but conversion into ammonia takes place even in the presence of added preservatives. Solid excrements mixed with water and allowed to rot give a fertiliser having properties equal to that of a mixture of solid excrement and urine. The organism which effects fermentation of animal urine is *Micrococcus urea* Cohn.—W. P. S.

Precipitation of phosphoric acid in the form of ammonium phosphomolybdate. Clarens. See XXIII.

Estimation of phosphoric anhydride as ammonium phosphomolybdate. Clarens. See XXIII.

Fertiliser for ponds; Production of a —. M. Engerls, Berlin. Ger. Pat. 302,255, Jan. 11, 1916. Addition to Ger. Pat. 301,550.

REEDS and other water weeds are treated with a mixture of nitric and sulphuric acids (e.g., spent nitrating acid), and the product is neutralised.—W. P. S.

Fertiliser; Preparation of a phosphatic water-soluble —. A.-G. der Chem. Produkten-Fabr. Pommerensdorf, Stettin, and R. Siegler, Pommerensdorf. Ger. Pat. 302,357, Apr. 6, 1916.

RAW phosphate, during or after treatment with sulphuric acid, is treated with sodium bisulphate or sodium sulphate and a quantity of water sufficient to dissolve the phosphoric acid and sodium phosphate; the solution is separated from calcium sulphate, ammonia is added to precipitate iron and aluminium, the solution is then evaporated, and mixed with potassium sulphate or ammonium sulphate or both.—W. P. S.

Calcium cyanamide; Process for improving the physical character of crude —. F. Steimnig, Hanover. Ger. Pat. 303,679, Aug. 1, 1915.

CRUDE calcium cyanamide is mixed with a dry, hydrated neutral salt, such as sodium sulphate, free from chlorine, or with an anhydrous salt and subsequently with a quantity of water sufficient to hydrate the salt, and the mixture is stirred until a non-dusty, friable crystalline meal is obtained.

XVII.—SUGARS; STARCHES; GUMS.

Beetroot molasses; Neutral and acid polarisation of vinasses from —. H. Pellet. *Bull. Assoc. Chim. Sucr.*, 1917, 35, 40–43.

THE polarimetric reading of vinasses from beet molasses is practically the same in presence of hydrochloric acid as in presence of excess of sulphurous acid. This confirms the validity of the use of the direct polarisation of beet molasses taken in presence of sulphurous acid, for comparison

with the inversion polarisation in presence of hydrochloric acid, in calculating the sucrose-content of the molasses. (Cp. Ogilvie, this J., 1912, 1195.)

—J. H. L.

Furfuroids (furfurosans); Determination of — in products of beet-sugar factories. I. R. Gillet. *Bull. Assoc. Chim. Sucr.*, 1917, 35, 53–62.

THE pectic substances of beets, according to Herzfeld, yield a certain amount of furfural when distilled with hydrochloric acid by Tollens' method. With the object of adapting this method to the determination of pectic substances in beet juices, etc., the author first investigated the behaviour of sucrose when distilled with hydrochloric acid by the Tollens-Coulenc procedure. According to Chalmot, sucrose yields not more than 0.2% of furfural, but the author, in spite of precautions to ensure uniformity of procedure, obtained results fluctuating between 0.38 and 0.76%. In operating on materials containing a large proportion of sucrose or hexoses, therefore, it is not possible to make a satisfactory correction for the influence of the sugar, but it appears practicable to eliminate the latter by fermentation before the distillation with acid. (See also *J. Chem. Soc.*, July, 1918.)

—J. H. L.

XVIII.—FERMENTATION INDUSTRIES.

Mucor Boulard; Acids produced by —. Bettinger and Delavalle. *Bull. Assoc. Chim. Sucr.*, 1917, 35, 13–15. (See also this J., 1918, 219 A.)

DATA respecting the production of acids by *Mucor Boulard* in sugared extract of malt-combs and also in liquefied grain mash, are given, confirming the general statements previously made (*loc. cit.*). In the liquefied grain mash, the initial acidity of which corresponded with 1.85 grms. of sulphuric acid per litre, the organism was cultivated at 30° and at 37° C. and the mycelium was immersed at frequent intervals; in 4 days the acidity had increased by 1.7–2 grms. per litre at the lower and by 0.5–0.6 grm. per litre at the higher temperature. After the fourth day the acidity diminished in both cases. In sugared extract of malt-combs considerably higher acidities were produced under favourable conditions, as regards aeration, temperature, and sugar-content of the medium. About 21% of the dry substance of the plants grown in this medium was soluble in ether.—J. H. L.

Cognacs and wine distillates; Composition of —. A. Jonscher. *Z. öfientl. Chem.*, 1918, 24, 25–36.

ANALYSES of French and German wine distillates show that the former now more nearly resemble the latter in composition, particularly as regards the amount of higher alcohols. Whilst the French products used to contain from 150 to 300 mgrms. of higher alcohols per 100 c.c. of absolute alcohol, the quantity now rarely exceeds 80 mgrms. Of twenty-six German cognacs examined, only five contained more than 100 mgrms. of higher alcohols per 100 c.c. of alcohol; in the remainder of the samples the quantity varied from 20 to 79.8 mgrms. Three out of five samples of French cognac contained less than 100 mgrms. of higher alcohols.—W. P. S.

Fermentation of vegetable tannin-colloids. Moeller. See XV.

Neutral and acid polarisation of vinasses from beet molasses. Pellet. See XVII.

PATENTS.

Beverage; Non-alcoholic carbonated —. W. J. Eisenbeiss, Chicago, Ill. U.S. Pat. 1,262,472, Apr. 9, 1918. Date of appl., Nov. 4, 1916.

BRAN is steeped in a saline liquid to extract the albumin, water and sweetening matter are added, and the whole is boiled and hopped. Colouring matter may be added, and when cooled the liquid may be acidulated and carbonated, or treated with vinegar and slightly carbonated and then filtered and again carbonated. Special claim is made to the extraction of albumin, in a soluble form, from vegetable matters, by steeping them in a saline liquid at 38°–50° C., whereby peptase is set free.

—J. H. L.

Beer rich in protein; Production of —. Nathan Institut A.-G., Zürich. Ger. Pat. 301,830, Sept. 12, 1915. Under Int. Conv., Sept. 9, 1915.

THE primary fermentation is carried out, with a sufficient quantity of yeast, at a low temperature, e.g., 0°–6° C., so as to effect the maximum decomposition of sugar and proteins whilst minimising the assimilation of nitrogenous matters by the yeast. To accelerate fermentation the amount of yeast employed may be increased, even to 3 litres or more per 100 litres of wort.—J. H. L.

Preparation of a lipid nitrogenous compound from yeast. Ger. Pat. 302,220. See XX.

XIXA.—FOODS.

Butter fat; Determination of fatty acids in —. D. B. Holland and J. P. Buckley. J. Agric. Res., 1918, 12, 719–732.

THE method described consists in the direct esterification of the fat and subsequent fractionation of the resulting esters. For the esterification, 150 grms. of the fat is boiled for 24 hrs. with 400 c.c. of absolute alcohol containing 8 grms. of hydrogen chloride or 4 c.c. of concentrated sulphuric acid; after cooling, 50 c.c. of ether and 150 grms. of magnesium chloride are added, the mixture is shaken gently, the lower layer is then drawn off, and the esters are shaken two or three times with 50 c.c. of ether and 50 c.c. of alcoholic magnesium chloride solution (250 grms. of dry magnesium chloride in 500 c.c. of absolute alcohol). The esters are filtered (the filter is afterwards washed with ether and the ethereal solution added to the alcoholic solution and a further small quantity of esters separated from the latter) and distilled; the condenser is filled with water at the outset, but no circulation of water is permitted during the distillation. After the alcohol and ether have been separated, the distillate between 85° and 365° C. is collected. The combined distillates from two portions of 300 grms. of butter fat are then redistilled and fractions are collected separately at the following temperatures:—125°–180° (ethyl butyrate, caproate, and oleate); 180°–225° (ethyl caproate, caprylate, and oleate); 225°–270° (ethyl caprylate, caprate, and oleate); 270°–300° (ethyl caprate, laurate, and oleate); 300°–325° (ethyl laurate, myristate, and oleate); 325°–365° (ethyl myristate, palmitate, and oleate). The proportions of the various fatty acids are then calculated from the saponification and iodine values of the fractions. The percentage quantities of fatty acids in butter fat were found to be: Caproic acid, 1.36; caprylic acid, 0.97; capric acid, 1.83; lauric acid, 6.89; myristic acid, 22.62. Butyric acid (3.15%) and palmitic acid (19.23%) were determined by difference, stearic acid (11.38) by crystallisation, and oleic acid (27.34%) was calculated from the iodine value of the insoluble acids.—W. P. S.

Fat in milk; Influence of paraffin on the Gerber method for the determination of —. F. Reiss. Milchwirtsch. Zentr., 1918, 47, 52–54.

PARAFFIN wax is sometimes used on the stoppers of sulphuric acid carboys, and it may happen that some of the paraffin finds its way into the acid. When such acid is used in the Gerber method, the paraffin separates together with the butter fat and increases the quantity of the latter proportionally; each 0.01 c.c. or 0.0079 grm. of paraffin increases the amount of butter fat by 0.10%.—W. P. S.

Kafir kernel; Physical and chemical study of —. G. L. Bidwell. U.S. Dept. Agric., Bull. No. 634, Apr. 4, 1918. [6 pages.]

THE composition of kafir kernel (dawn kafir or dwarf blackhull) and its various parts is as follows, the figures being calculated on the dry substance:—

	% of whole kafir.	Ash.	Ether extract.	Crude protein.	Crude fibre.	Pen-to-sans.	Starch.
Whole kafir ..	100	1.8	4.1	12.7	1.8	3.3	61.9
Pure endo-sperm ..	83.9	0.3	0.7	12.7	0.8	1.9	69.3
Pure germ ..	10.0	13.2	31.5	19.3	3.8	6.1	—
Pure bran ..	6.1	2.0	6.8	4.8	16.2	18.4	—
Starchy endo-sperm ..	35.0	0.3	0.8	10.1	0.8	1.6	70.4
Horny endo-sperm ..	48.9	0.3	0.7	13.7	0.7	1.6	68.8

These figures show that kafir kernel has a composition similar to that of maize.—W. P. S.

Salicylic acid in foods; Estimation of —. H. D. Steenberg. Chem. Weekblad, 1917, 14, 914–921. Z. angew. Chem., 1918, 31, Ref., 106.

A ROUND-BOTTOMED flask containing 66 c.c. of benzene and a few pieces of tile is connected with an extraction apparatus containing 50 c.c. of benzene to which an amount of the material under examination equivalent to about 5 mgrms. of salicylic acid is added, together with 2 c.c. of 4 N sulphuric acid, a little alcohol, and just sufficient water to cause the benzene to run over. The whole is connected with a condenser and the extraction carried on for six hours. After cooling, a few c.c. of benzene from the extractor are shaken with water and a drop of ferric chloride solution (1 in 1000). If this gives no salicylic acid reaction the whole of the benzene is shaken in a separating funnel with two separate 5 c.c. of N/10 potassium hydroxide and then washed with water. The resulting united aqueous extracts are evaporated to dryness and the residue transferred by means of 10 c.c. of N/10 hydrochloric acid and 20 c.c. of water to a long-necked stoppered flask. To this are added 1 c.c. of hydrochloric acid (sp. gr. 1.13) and 10 c.c. of a solution containing 1.67 grms. of potassium bromate and 6 grms. of potassium bromide per litre, a blank test being performed at the same time. After a quarter of an hour 6 c.c. of N/2 potassium iodide and 1 c.c. of chloroform are added to each, and the liberated iodine titrated with N/80 thiosulphate.

—W. G.

Straw; Treatment of — for preparation of fodder. B. Tollens. J. Landwirts., 1917, 65, 219–232. Z. angew. Chem., 1918, 31, Ref., 105–106.

ACCORDING to Lehmann the digestibility of the organic matter of winter-sown cereal straw can be taken as 42%, and the different processes of treatment aim at increasing this value. Lehmann's pressure method using a minimum of soda (2% of

the straw) increases the digestibility to 60–62%, and the product can be fed without danger. By employing more soda (10% of the weight of the straw) the digestibility can be increased to 74%, but the product must be washed with water, thus entailing a loss of 30% of the original straw. The increased value of these products balances this loss, but it is an open question whether the process justifies the increased expenditure on soda. Lehmann's process without pressure, but using more soda (10%), also requires that the material be washed, and again there is a loss of organic matter. This method increases the digestibility to over 70%, but requires a longer time than the pressure method. Similar results were obtained by Colmann in experiments carried out at Dahlem, using closed boilers without pressure and with excess of soda. The treatment without pressure or shaking yields a material ("*Kraftstroh*") which is still of the nature of straw. By treatment under pressure a uniform mass is obtained which in the wet state can be fed satisfactorily; in the dry state, however, it is similar to cardboard and is not satisfactory to feed. If the wet "*Kraftstroh*" is mixed with molasses, potatoes, or with products rich in nitrogen and dried, a mixture is obtained which keeps well, can be transported, and is readily consumed. The treated straw has a digestibility exceeding that of meadow hay (60%) and equal to that of clover (70%). It is rich in carbohydrates but poor in nitrogen, and would require supplementing in this respect as a food.—W. G.

Straw; Method of distinguishing treated from raw — and the determination of digestible fibre. F. Mach and P. Lederle. Landw. Versuchstationen, 1917, 90, 269–289. Z. angew. Chem., 1918, 31, 1918.

A METHOD for distinguishing between raw straw and that which has been treated with alkali consists in determining the soluble portion of the crude cellulose by treating the material with ammoniacal cupric hydroxide and precipitating the dissolved cellulose, etc., with alcohol and acetic acid; the insoluble portion is then used for the determination of the crude fibre.—W. P. S.

Feeding stuffs; Influence of natural and artificial drying on the digestibility and assimilation of —. Völtz. Chem.-Zeit., 1918, 42, 147.

NATURALLY dried fodders, such as hay, are but slightly less digestible and assimilable than freshly mown grass, but artificial drying produces considerable changes; loss of digestibility in this case is due principally to the temperature which the substance attains during the process, and is less dependent on the temperature of the drying apparatus. The proteins are most affected, and 36% of the digestible protein may be lost; carbohydrates are less affected, and fats least of all.

—W. P. S.

PATENTS.

Vegetable-ivory meal and method of making same. R. M. Chapman, Hammond, Ind., Assignor to R. W. Chapin, Chicago, Ill., and G. M. Chapin, Hammond. U.S. Pat. 1,260,327, Mar. 26, 1918. Date of appl., Dec. 29, 1917.

VEGETABLE-IVORY material is heated at about 280°–320° F. (138°–160° C.) in a bath of 1 to 2% sulphuric acid or other disintegrating liquid until it is friable and is then reduced to a porous meal, which contains mannose, dextrose, and a fairly high proportion of fat.—C. A. M.

Foodstuffs; Manufacture of — [from oil-cakes]. H. Bollmann, Hamburg, Germany. U.S. Pat. 1,260,656, Mar. 26, 1918. Date of appl., Jan. 3, 1918.

EXPRESSED oil-cake or other foodstuff is leached in a heated condition with a solvent composed of alcohol and a volatile liquid hydrocarbon (benzene) which will dissolve fat, so as to extract the oil and bitter substances and leave a residue suitable for food.—C. A. M.

Sterilisation of milk and other albuminous liquids. H. Laessig, Berlin. Ger. Pat. 301,966, Sept. 5, 1915.

THE liquid is heated almost to the necessary temperature by being caused to flow over a corrugated surface maintained at a temperature insufficient to cause coagulation of the albumin, and the flowing liquid is raised to the degree needful for rapid sterilisation by radiation from a heated surface above.—D. F. T.

Cattle feeding stuff; Manufacture of —. Futtermittel- u. Getreidehandel-A.-G., Halle. Ger. Pat. 302,342, June 30, 1914.

IN the preparation of compressed cakes of feeding stuffs by atomising the material in contact with a spray of drying oil to act as binding material, the absorption of the oil by the feeding stuffs, as far as possible, restricted to the surface layer of the latter by mixing with the feeding stuff an inert material, such as clay, bolus, or the like, which has a greater absorptive power for the oil, or by dissolving in the oil a substance, such as rosin, which increases its viscosity, or by using an aqueous solution or emulsion of the oil.

Baking powder. L. Elkan Erben, G.m.b.H., Charlottenburg. Ger. Pat. 303,058, Feb. 11, 1916.

A BAKING powder, produced by mixing carbonates with protein acids such as casein or nucleic acid, possesses the advantage that the carbon dioxide is liberated only slowly, and that the resulting protein salts possess agglutinating properties.—D. F. T.

Hydrogenating resistant [acid] fatty material for edible purposes. U.S. Pat. 1,262,911. See XII.

XIXb.—WATER PURIFICATION; SANITATION.

Water analysis in the field. G. W. Halse and A. S. Behrman. Philippine J. Sci., 1918, 13, A, 1–17.

THE methods are based on those of Leighton (U.S. Geol. Survey, Water Supply Paper (1905) No. 151). Iron is determined colorimetrically with potassium thiocyanate. Sulphates after precipitation as barium sulphate and suspended matter are determined turbidimetrically by measuring the depth of turbid liquid in a tube required to extinguish the illumination at one end due to a flash lamp. Titrations of alkalinity, acidity, etc., are made against standard pellets of reagent in a glazed porcelain mortar, the water being measured in a 100 c.c. graduated cylinder. Accuracy to within 5% is claimed. Pellets of sodium bisulphate bound with glucose are used with "butter yellow" as indicator for the determination of alkali, and with phenolphthalein to measure normal carbonates. Sodium carbonate pellets bound with kaolin are used for titrations of acidity, different indicators being used to distinguish between mineral acids and carbonic acid. For chlorides, pellets of silver nitrate made with a kaolin binder are used, and

potassium chromate indicator. For total hardness determination see following abstract. Bacteriological examinations are made in apparatus sterilised in the laboratory and carried in sealed tins or paper envelopes. The whole equipment is portable and weighs less than 20 kilos.—H. J. H.

Total hardness of water; Field methods for determination of —. A. S. Behrman. Philippine J. Sci., 1918, 13, A, 21—27.

BLACHER'S method of titration with potassium palmitate (this J., 1912, 555; 1913, 158) has been adapted to field conditions. Standard pellets are made by neutralising a known weight of palmitic acid with potash in alcoholic solution. The residue after evaporation to dryness is incorporated with glucose and made into pills. These lose strength on storing, and require frequent checking by titration with calcium sulphate using phenolphthalein as indicator. Water to be titrated is rendered just acid with sulphuric acid, and carbon dioxide is removed by bubbling air through the liquid, which is then neutralised with alcoholic potash. Pellets are now added until a deep red coloration is produced. An alternative method is to crush a number of pellets in a mortar and add the neutralised water from a graduated cylinder until the end point is reached. The result may be checked by adding one or more pellets and again titrating with water to the end point. An accuracy of about 5% is claimed.—H. J. H.

Activated sludge and treatment of packing-house wastes. L. Pearse. J. Amer. Leather Chem. Assoc., 1918, 13, 145—159.

THE activated sludge process offers the best promise for the treatment of packing-house wastes. Extensive experiments are to be carried out in Chicago. Results obtained up to the present (compare this J., 1916, 904) indicate that 4—6 cub. ft. of air per second per gallon of sewage is sufficient to produce a stable effluent. The larger quantity is needed in winter. Full details of the experiments are given.—F. C. T.

Dust in mine air; Estimation of injurious — by the Kotzé konimeter. J. Innes. J. Chem. Met. Min. Soc. S. Africa, 1918, 18, 199—206.

THE gravimetric results obtained by the sugar-tube method hitherto employed are misleading in the absence of efficient means for eliminating non-injurious dust, i.e., particles of greater diameter than 5 microns, since the weight of the deposit is largely that of the coarser constituents. In the konimeter method a known quantity of the air is caused to impinge at a high velocity (30—120 metres per second) from a fine nozzle (0.6—1.0 mm. in diameter) on to the surface of a glass slide which is thinly coated with vaseline, and in the dust spot so obtained separate counts are made of the particles of larger and smaller diameter than 5 microns, the latter constituting "injurious dust" from the miners' phthisis standpoint. The apparatus consists of a small suction pump the piston of which is actuated by a spiral spring and contained in a cylinder of such dimensions that, on release of the spring by means of a trigger, the piston displaces exactly 5 c.c. This quantity of air is drawn rapidly through the nozzle and impinges on the vaselined plate before passing into the cylinder. The concordance of the results obtainable with the konimeter, and the misleading character of the indications afforded by the gravimetric method, are shown in micrographic and other data relating to a series of 36 tests.

—W. E. F. P.

"Perocide" liquor as a substitute for copper-lime liquor. O. Appel. Apoth.-Zeit., 1917, 32, 275. Z. angew. Chem., 1918, 31, Ref., 21.

A MIXTURE of sulphates of the rare earths, consisting mainly of cerium and didymium sulphates, obtained as a by-product in the manufacture of incandescence gas mantles, is sold under the name of "perocide." It contains at least 45% of cerium oxide, and when mixed with milk-of-lime may be used for destroying mildew on vines, scab on stone-fruit trees, etc. Its insecticidal action is about one-half of that of mixtures prepared from copper sulphate and lime.—W. P. S.

PATENTS.

Disinfectant. Tetralin G.m.b.H., Berlin. Ger. Pat. 302,003, May 27, 1916.

THE *ar*-tetrahydronaphthols (this J., 1890, 603) and their derivatives substituted in the aromatic nucleus by nitro groups, mercury salt residues, alkyl groups, or halogens, possess marked disinfectant power, greatly in excess of that exhibited by the parent naphthols; they may be applied in the free condition or in the form of salts, either alone or dissolved in sulphuric acid or in aqueous solutions of alkali salts of the fatty or sulphonated fatty acids, with or without the additional presence of formaldehyde.—D. F. T.

Insecticide; Production of an —. O. Hinsberg, Nackenheim. Ger. Pat. 302,238, Apr. 24, 1917.

TOBACCO waste, quassia wood, capsicum, valerian, or similar material is subjected to dry distillation, and the distillate is collected in a suitable solvent. The solution forms a basis for sprays.—W. P. S.

Disinfectant dressing; Production of a —. Deutsche Desinfektionsmittelfabrik Lipschitz u. Co., Berlin-Wilmersdorf. Ger. Pat. 303,737, Aug. 26, 1915.

Dry powdered peat is carefully treated with caustic alkali solution, and the mixture is then saturated with chlorine at a temperature below 90° C. The dry powdery product retains most of its chlorine even after long storage, and is capable of absorbing up to ten times its own weight of liquids; it is therefore of value as a dressing, particularly for suppurating wounds.—D. F. T.

Disinfectants containing halogenated phenols or phenolic salts; Production of —. Carbonsäure-Fabrik G.m.b.H., Ladenburg. Ger. Pat. 303,738, July 13, 1915.

SALTS of phenol with the alkali or alkaline-earth metals are mixed with hypohalogenites of the alkali or alkaline-earth metals in the absence of a solvent. Calcium phenoxide and bleaching powder in this way yield the calcium salt of mono-, di-, or trichlorophenol, and the product possesses the advantage that it can be sprinkled.—D. F. T.

Nitro-compounds of phenols; Non-explosive disinfectants and preservatives containing —. Chem. Fabr. Försheim H. Noerdlinger. Ger. Pat. 304,127, Feb. 20, 1914.

THE disinfecting and preserving properties of the alkali salts obtained by dissolving in alkali solution the product obtained by passing air, oxygen, or ozonised air through heated wood-tar (Ger. Pat. 163,446 and Eng. Pat. 8590a of 1905; this J., 1906, 367, 529), are increased by admixture of nitro-compounds of phenols. The concentrated mixtures so obtained may be reduced to a fine dry powder by heating on a water-bath, and, in some cases, at reduced pressure.—B. V. S.

Preparation of a derivative of hexamethylene-tetramine. Ger. Pat. 303,450. See XX.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Peppermint oil; Japanese —. H. Walbaum. J. prakt. Chem., 1917, 96, 245-250.

THE fraction of Japanese peppermint oil of b.pt. 250°-310° C., sp. gr. at 15° C. 0.9490, consists largely of α -hexen-1-yl phenylacetate

$\text{CH}_3(\text{C}_6\text{H}_5)\text{CO}_2\text{CH}_2\text{CH}_2\text{CH}(\text{CH}_2\text{CH}_2\text{CH}_3)$, which when prepared in a pure condition is a liquid of onion-like odour, b.pt. 135°-136° C. at 4 mm., 290° C. at 760 mm.; sp. gr. at 15° C. 1.000; n_D^{25} = 1.49810. Several other synthetic esters of the alcohol are described. The isomeric β -alcohol has already been detected together with its corresponding aldehyde in the green leaves of numerous plants (Curtius and Franzen, this J., 1912, 706, 958; 1914, 1026). (See also J. Chem. Soc., June, 1918.)

—D. F. T.

Determination of lactic anhydride in lactic acid. Thompson and Suzuki. See XV.

Estimation of iron in lactic acid. Harvey. See XV.

PATENTS.

Salicylic acid; Manufacture of —. M. Theodor, London. Eng. Pat. 115,080, Apr. 24, 1917. (Appl. No. 5755 of 1917.)

CRUDE salicylic acid is dried, preferably under vacuum, and heated to about 170° C. The melted acid is kept in thorough agitation by means of a stirrer, and a current of dry air, or other gas which does not act on the acid, previously heated to about the same temperature, is blown through the mass. The gas containing the volatilised salicylic acid is then passed through a condenser, or series of condensers, maintained at suitable temperatures, e.g., a series of three may be used, the first at 120° C., the second at 95° C., and the third at 40° C. On leaving the last of these, the gas is passed through a trap or filter to retain any crystals not previously deposited. Any impurities present in the crude acid which may be volatilised, e.g., phenol, etc., remain in the gas as vapour after passing through the apparatus.—L. A. C.

Carbon tetrachloride; Process of separating — from other compounds. Process of making carbon tetrachloride from carbon bisulphide and chlorine. G. Baillo, Assignor to Isco Chemical Co., Niagara Falls, N.Y. U.S. Pats. (A) 1,260,621 and (B) 1,260,622, Mar. 26, 1918. Date of appl., Apr. 30, 1917.

(A) A MIXTURE of carbon tetrachloride, sulphur monochloride, and carbon bisulphide is treated with sufficient tin to decompose all the sulphur monochloride into free sulphur and stannic chloride. The sulphur is separated, and sufficient water added to hydrate the stannic chloride. The carbon tetrachloride is then separated from the mixture by distillation. (B) Carbon bisulphide containing free sulphur is treated with an excess of chlorine in the presence of a catalyst, carbon tetrachloride and sulphur dichloride being formed. On the addition of a further quantity of carbon bisulphide to the mixture, this is converted into carbon tetrachloride, and sulphur monochloride is produced. The constituents of the mixture are then separated as described above, the sulphur monochloride converted into sulphur dichloride by treatment with chlorine, and this used for the production of more carbon tetrachloride.—L. A. C.

Organic condensation products; Process for the synthesis of —. H. Ilbert, Assignor to E. I. du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 1,261,811, Apr. 9, 1918. Date of appl., Nov. 28, 1913.

AN organic compound containing a carbon atom and an oxygen atom united by a double bond (e.g., an aldehyde) is treated with an alkali metal (e.g., sodium) in the presence of an anhydrous liquid organic compound capable of forming a salt with the alkali metal.—L. A. C.

Chlorinated hydrocarbons; Manufacture of — [from natural gas]. J. B. Garner and H. D. Clayton, Pittsburgh, Pa., Assignors to Metals Research Co., New York. U.S. Pat. 1,262,769, Apr. 16, 1918. Date of appl., June 23, 1915.

HYDROCARBONS (natural gas) and chlorine are mixed in a body of charcoal at a low temperature, and then passed through a body of charcoal heated to about 300° C. The chlorinated hydrocarbons are condensed, and the hydrogen chloride absorbed in water.—L. A. C.

p-Aminophenol; Therapeutically valuable derivatives of —. M. Hartmann, Assignor to Society of Chemical Industry in Basle, Switzerland. U.S. Pat. 1,263,238, Apr. 16, 1918. Date of appl., June 29, 1917.

Acyl derivatives of *p*-aminophenol allyl ether, e.g., *p*-acetaminophenyl allyl ether (leadlets, m. pt. 94° C.), which are crystalline substances, fairly soluble in water and readily soluble in alcohol, ether, and other organic solvents, possess narcotic, sedative, and anti-neuralgic properties.—D. F. T.

Mercury succinimide; Production of derivatives of — easily soluble in water. A. Bernard Nachfolger-Einhornapotheke, Berlin. Ger. Pat. 302,156, Sep. 16, 1916.

MOLECULAR proportions of an alkali salt of monomethylarsinic acid and mercury succinimide are mixed in aqueous solution with the formation of a double compound which may be isolated by crystallisation or evaporation preferably under reduced pressure. The compounds obtained in this way will yield 8% solutions in water, and 3-4% solutions, which contain more than 0.01 gm. of mercury per c.c., can be injected subcutaneously without causing the irritation commonly observed with mercury salts, but yet exerting a rapid therapeutic action. The double salts in question are insoluble in the common organic solvents and are decomposed by mineral acids.—D. F. T.

Lipoid, nitrogenous compound; Production of a — from yeast. Ges. für Chem. Ind. in Basel. Ger. Pat. 302,229, Jan. 25, 1916. Under Int. Conv., Dec. 19, 1914.

AFTER removing the solvent from the alcoholic extract of yeast by adding water and distilling under reduced pressure, the resulting emulsion is shaken with ether; the ethereal solution is then treated with acetone, when the fats, cholesterol, and ethereal oils remain in solution, whilst a substance is precipitated capable of coagulating blood; the precipitate is again extracted with ether and the ethereal solution evaporated to dryness under reduced pressure.—D. F. T.

Digestive preparation enriched in crepsin; Production of a —. F. W. Hopmann, Cologne. Ger. Pat. 302,294, Mar. 27, 1915.

CRUDE crepsin prepared in the ordinary way by precipitation with calcium salts is dried and

powdered, and then treated repeatedly with extracts of erepsin from the intestinal membrane. The final product is a stable white powder which yields erepsin to dilute hydrochloric acid; this solution has the power of effecting the rapid and complete hydrolysis of peptone in neutral or feebly alkaline solution.—D. F. T.

Tropic acid; Preparation of —. Chem. Werke Grenzach A.-G., Grenzach. Ger. Pat. 302,737, May 18, 1916.

OPTICALLY inactive tropic acid, identical with the product obtained from atropine and suitable for the manufacture of pharmaceutical preparations, is prepared by hydrolysis of its ester, which is formed by the reduction of ethyl oxymethylenephénylacetate.—D. F. T.

Proteins; Preparation of compounds of — with the heavy metals. K. Kottmann, Berne, Switzerland. Ger. Pat. 302,911, June 9, 1916. Addition to Ger. Pat. 300,513.

PROTEIN substances from animal organs and tissues which have been freed from soluble degradation products so that they no longer give the ninhydrin reaction, are treated with compounds of the heavy metals or with the heavy metals in a colloidal form. The products are especially suited to therapeutic application and do not produce undesirable side-effects as do similar substances prepared from protein which has not been purified. The metal is present in them in the non-ionised condition, but can be liberated by the action of enzymes capable of hydrolysing the protein matter.—D. F. T.

Ethanoltrialkylarsonium hydroxides and their salts; Preparation of —. Chem. Werke Grenzach A.-G., Grenzach. Ger. Pat. 303,032, Jan. 25, 1916.

WHEREAS the hydrolysis of ω -bromoethyltriethylarsonium bromide $\text{CH}_3\text{Br}\cdot\text{CH}_2\cdot\text{As}(\text{C}_2\text{H}_5)_3\text{Br}$ by silver oxide is known to cause concurrent elimination of hydrogen bromide with formation of vinyltriethylarsonium hydroxide, the same salt on treatment with water at higher temperatures yields ethanoltrialkylarsonium hydroxide

possessing valuable therapeutic properties.

—D. F. T.

Ricinostearolic acid; Preparation of a crystalline ester of the di-iodide of —. J. D. Riedel Akt.-Ges., Berlin-Eritz. Ger. Pat. 303,052, Mar. 14, 1914.

THE di-iodide of ricinostearolic acid may be converted into its ethyl ester, or ethyl ricinostearolate may be caused to form the additive compound with iodine, the resulting product, as compared with the methyl ester, being unexpectedly crystalline.—D. F. T.

Hexamethylenetetramine; Preparation of a derivative of —. L. Egger, Buda Pesth. Ger. Pat. 303,450, Jan. 23, 1915. Under Int. Conv., Jan. 31, 1914.

HEXAMETHYLENETETRAMINE and a molecular proportion of acetylsalicylic acid are ground with a quantity of alcohol insufficient to dissolve the former by itself, until complete dissolution is effected, and the hexamethylene-tetramine acetylsalicylate is allowed to crystallise. The product shows a greater bactericidal power than the corresponding non-acetylated compound.—D. F. T.

Camphor; Preparation of emulsions of —. Saccharin-Fabrik A.-G. vorm. Fahlberg, List & Co., Magdeburg. Ger. Pat. 303,537, June 29, 1913.

By dissolving camphor in a small quantity of ether or methyl alcohol and treating the solution with water in the presence of lipoids such as blood alcohols, lecithin, or oxysterol, permanent emulsions can be obtained containing 5% of camphor, which are without harmful action on the blood and can therefore be injected intravenously.—D. F. T.

Lithium acetylsalicylate; Preparation of compact, friable tablets of —. J. A. Wülfig, Berlin. Ger. Pat. 304,574, Jan. 12, 1917.

THE tablets consist of a mixture of lithium acetylsalicylate with an alkali carbonate, particularly sodium bicarbonate. The addition of 5% of the alkali carbonate is sufficient to form tablets which do not harden and which even after keeping for a month remain readily soluble in water.—L. A. C.

[*Dicresyl carbonate.*] Substitute for lubricating oil and glycerin. Ger. Pat. 302,361. See IIA.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Development of the image in a dry plate negative; Mechanism of —. F. W. T. Krohn. Phot. J., 1918, 58, 179–194.

A DESCRIPTION is given of the appearance of cross-sections of developed film over a very wide range of exposure. If a film is exposed until a visible image is formed, so that reversal would show on development, and is then fixed without development, a red image is left which has the appearance under the microscope of shells of light-reduced silver. It is suggested that these shells, probably along with surrounding films of gelatin halide, act as protective coverings for the silver halide grains and so retard development. The inertia of a plate is found to vary according to the development it receives, being a maximum at about $\gamma=0.8$. In an example given the inertia was 0.22 at $\gamma=0.295$, time of development = $\frac{1}{3}$ min., 0.19 at $\gamma=0.8$, time = 2 mins., and 0.36 at $\gamma=2.7$, time = 12 mins.; taking $\gamma=0.8$ to $\gamma=1.4$ as the range of normally useful development factors, the variation of the inertia value from the value at $\gamma=1$ is on the average –13% on one side and +26% on the other. Constancy of inertia over a fairly wide range of γ values was found generally only with an easy tendency to fog. The author has observed that low densities develop to their maximum more quickly than high densities, and it is suggested that the change of inertia may be due to this. The variation of plate curves with strength of developer was also examined and a developer half the strength of that originally recommended by Hurter and Driffield (this J., 1890, 455; 1896, 100) was found to give a longer straight line portion in the curve and a lower inertia than either stronger or weaker developers. The addition of increasing quantities of bromide to the developer was found to give an increasingly lower rate of development, higher inertia, and somewhat longer range.—B. V. S.

[*Colour*] sensitising [photographic plates]; A new method of —. E. König. Phot. Rundsch., 1917, 54, 257–258. Z. angew. Chem., 1918, 31, Ref., 102.

PLATES are not sensitised by bathing in a pure alcoholic dye-solution, but may be sensitised if the alcoholic dye-bath is followed by a water bath.—B. V. S.

Colour-sensitive bathed photographic plates.
 Lalpo-Cramer. Phot. Ind., 1917, 657. Z. angew. Chem., 1918, 31, Ref., 102.

COLOUR sensitising of photographic plates by bathing as compared with the introduction of dyes into the emulsion confers greater sensitiveness with, however, loss of keeping quality. The latter may be increased at the expense of the former by introducing some potassium bromide into the dye-bath.

—B. V. S.

PATENTS.

Photographic pictures on silver mirrors; Process for the production of —. J. Riedler, Berlin-Steglitz. Ger. Pat. 301,929, Sept. 12, 1916.

A SILVERED glass plate is coated with a light-sensitive film such as caoutchouc and asphalt, exposed under a line or half-tone negative, developed in acetone or the like, etched through to the glass with any suitable solvent of the silver film and then coated with a coloured backing as desired.

—B. V. S.

Positives; Process for the photographic preparation of — from positives. R. Kögel, Beuron. Ger. Pat. 302,786, Nov. 10, 1916.

THE printing film contains a light-sensitive diazo compound which can be developed by amines or phenols to a stable azo dye, but loses this property on exposure to light. Where the effect of exposure is not visible a print-out image may be obtained by the addition of a suitable bleach-out dye. If a suitable de-sensitiser or fixing bath be employed, this dye helps to strengthen the picture.

—B. V. S.

[Palladium] toning of silver chloride emulsion papers; Process for —. Kraft and Stendel Fabr. phot. Papiere, G.m.b.H., Dresden. Ger. Pat. 302,817, Oct. 3, 1916.

THE toning bath contains at least 0.3% of concentrated hydrochloric acid and 1% of alum, e.g., potassium chloro-palladate, 1 grm., hydrochloric acid 1: 5, 15 c.c., alum, 15 grms., and water up to 1500 c.c. The hydrochloric acid prevents the formation of yellow stains in the gelatin film and the paper by precipitation of palladium hydroxide, and the formation of an opalescent fog especially in the shadows; the alum prevents softening of the gelatin, and, not being completely removed by washing, is effective also in the fixing bath. There must be at least 10 mins. washing between the toning bath and the fixing bath, which latter is a solution of ammonia, e.g., about 30 c.c. of concentrated ammonia per litre.—B. V. S.

Development films free from stick-marks; Preparation of —. Chem. Fabr. auf Aktien vorm. E. Schering. Ger. Pat. 303,144, Nov. 29, 1913. Addition to Ger. Pat. 295,502 (this J., 1917, 307).

To prevent stick-marks on development papers, etc., with baryta-coated supports, albumin is added to the baryta mixture.—B. V. S.

Photographic prints in colours; Paper for producing —. J. E. Thornton, London, Assignor to J. O. O'Brien, Manchester. U.S. Pat. 1,263,962, Apr. 23, 1918. Date of appl. May 24, 1915.

SEE Eng. Pat. 13,711 of 1914; this J., 1915, 818.

Photometry and apparatus therefor. Eng. Pat. 112,614. See XXIII.

XXIII.—ANALYSIS.

Thermocouples; Standardisation of base-metal —.
 P. D. Foote, T. R. Harrison, and C. O. Fairchild. Met. and Chem. Eng., 1918, 18, 403—408.

THE rapid method of calibrating base-metal couples by placing the hot junctions of the couples, together with the hot junction of a standard couple, close together in a suitable furnace and comparing the e.m.f.s. developed, though suitable for many industrial purposes, is liable to inaccuracy owing to the difficulty of obtaining an even distribution of temperature in the furnace. A more satisfactory method consists of immersing the hot junctions, suitably insulated, in a bath of molten tin, and comparing the readings at various temperatures. With this type of bath a range of 300° C. to 1000° C. may be obtained. The galvanometer resistance should be at least 300 ohms, otherwise change in the resistance of the circuit will have an appreciable effect upon the accuracy of the results. Should a low-resistance galvanometer have to be used, the resistance of the remainder of the circuit, i.e., the couple and connections, should be frequently checked and changes allowed for. In reading furnace temperatures it is essential that the depth of immersion of the couple should be sufficient to render negligible any error caused by the conduction of heat from the region of the hot junction by the protecting sheath of the couple. If the temperature gradient of the interior of the sheath is found to be small at the closed end this error may be neglected. It is essential that the cold junction temperature should be kept constant, which may be done by means of a water jacket or other device. Hot junctions may be made by fusing the ends of the two wires together, using borax as a flux. Afterwards the joint, whilst still hot, is dipped in water to remove borax.

—H. J. H.

Extraction apparatus; Laboratory —. C. G. Schwalbe and W. Schulz. Chem.-Zeit., 1918, 42, 194.

A MODIFICATION of the Besson extractor (Chem.-Zeit., 1915, 40, 860) in which no corks are employed and larger quantities (4–6 litres) of material may be extracted. The apparatus consists of a cylinder of tinfoil, E, in the upper part of which is fitted a wire ring which carries a fine cotton bag holding the material to be extracted. Above this bag is

fitted a cylindrical condenser, K, through which a stream of water flows. The apparatus is heated in a water-bath, W. All gas- and water-connections are made of metal so as to ensure the safety of the apparatus. (See also J. Chem. Soc., July, 1918.)

—A. B. S.

Potassium; Light filters for the detection of ——. A. Herzog. Chem.-Zeit., 1918, 42, 145.

GLASS plates coated with gelatin coloured by certain dyes may be used in the flame test for potassium. The most suitable screen is one having a coating containing 3.9 grms. of Patent Blue and 2.5 grms. of Tartrazine per sq. metre of glass. Viewed through this screen the potassium flame appears bright red fringed with yellowish-green. The rubidium flame is like the potassium flame, but this is the only element which cannot be distinguished from potassium by means of the screen. Violet and green dyes may be used in making the screen, but the combination mentioned above will be found to be the most useful.—W. P. S.

Gravimetric analysis; Time as a factor in ——. *Precipitation of barium sulphate.* Z. Karaglanow. Z. anal. Chem., 1918, 57, 77—98.

THE rate at which barium chloride solution is added has a considerable effect on the precipitation of barium sulphate; to obtain correct results the addition should be made gradually over a period of not less than 1.5 min. The precipitation is also affected by the concentration of the solution, but not by temperature. (See also J. Chem. Soc., July, 1918.)—W. P. S.

Phosphoric acid; Precipitation of — in the form of ammonium phosphomolybdate. J. Clarens. Bull. Soc. Chim., 1918, 33, 146—159.

A MORE detailed discussion of work already published. (Compare J. Chem. Soc., April, 1918.)—W. G.

Phosphoric anhydride; Estimation of — as ammonium phosphomolybdate. J. Clarens. Bull. Soc. Chim., 1918, 33, 159—163.

THE phosphoric anhydride is precipitated as ammonium phosphomolybdate, 100 c.c. of ammonium molybdate solution containing 15–20 grms. of ammonium nitrate, being used for a quantity of solution containing 0.1 gm. P_2O_5 . The precipitate is washed with distilled water and the nitrogen in it liberated by sodium hypobromite and measured in a nitrometer. Under the above conditions the nitrogen and P_2O_5 are present in the precipitate in the proportions requisite to form tri-ammonium phosphate. The method is not satisfactory for the estimation of phosphoric acid in the presence of sulphuric acid.—W. G.

Silver nitrate; Iodine titration of — with palladous nitrate as indicator. L. Schelder. J. Amer. Chem. Soc., 1918, 40, 583—593.

THE Volhard method for the volumetric estimation of silver is interfered with by the presence of certain metals and loses its sensitiveness for very dilute solutions. Silver solutions may, however, be titrated with iodide in the presence of such metals, and in very dilute solution, by the use of palladous nitrate as indicator. The indicator solution is prepared by dissolving 0.06% of palladous nitrate in 16% nitric acid; it is advisable to use a protective colloid along with the indicator to prevent the occlusion of potassium iodide or silver nitrate. For this purpose a 5% solution of gum arabic is most advantageous. The indicator is converted by the first excess of iodide into palladous iodide which gives the solution a reddish colour; this action is sensitive to 1 part in 500,000. The method is further to be recommended on account of the accuracy and easy reproducibility with both N/10 and N/1000 solutions. The author discusses at some length the possible errors of the method, and gives full details

of the procedure to be adopted for N/10 and N/1000 solutions.—J. F. S.

Lead; Volumetric determination of — by ammonium molybdate. Lindt. Z. anal. Chem., 1918, 57, 71—76.

AN excess of ammonium acetate should be avoided in dissolving the lead sulphate in this method (see Sacher, this J., 1910, 47). The ammonium acetate solution used may be prepared by adding 50% acetic acid to 25% (by weight) ammonia until the mixture is slightly acid to litmus paper. Correct results are obtained when just sufficient of this solution is employed to dissolve the lead sulphate; otherwise, the results are too high. (See also J. Chem. Soc., July, 1918.)—W. P. S.

Thorium and zirconium; Colour reaction of — with pyrogallol-aldehyde. H. Kaserer. Chem.-Zeit., 1918, 42, 170—171.

ON the addition of pyrogallol-aldehyde to solutions of thorium and zirconium compounds a yellow coloration is produced, and, on standing, or immediately on boiling or on addition of hydrogen peroxide, a dirty yellow precipitate and colourless solution. With cerous compounds a brownish-yellow colour is produced but no precipitate, even on boiling. On the addition of nitric, sulphuric, or hydrochloric acid the colour is discharged. The reagent is prepared by condensing a solution of 38 grms. of pyrogallol and 36.3 grms. of formamide in anhydrous ether with 15.2 grms. of phosphorus oxychloride and filtering after 12 hours. The residue is recrystallised from alcohol, to which sodium chloride is added, and the crystals are suspended in hot caustic soda through which a current of hydrogen is passed. The liquid is acidulated, the aldehyde extracted with ether, and purified by means of its bisulphite compound. (See also J. Chem. Soc., July, 1918.)—A. B. S.

PATENT.

Photometry and apparatus therefor. Siemens und
Halske Akt.-Ges., Siemensstadt, Germany. Eng.
Pat. 112,614, Sept. 29, 1917. (Appl. No. 14,096
of 1917.) Under Int. Conv., Jan. 12, 1917.

The apparatus is designed to allow alteration of colour of the standard light source without any alteration in its brilliancy, so that the determination of the luminosity of coloured light sources may be easily carried out. In the more general form the standard light is enclosed in a box with a rectangular opening containing three adjacent colour screens, red, green, and blue, of equal size and luminosity; in front of this opening are two adjustable shutters, each equal in width to that of one colour-screen, so that two thirds of the light passed by the composite screen is cut off, but the light passed may contain any desired proportions of the three colours. In another form the three colour screens are arranged on the sides of a triangle, and a single shutter of special shape and adjustable in two directions is used. For some special purposes, especially where a number of lights differing only slightly in colour are to be compared, a simpler arrangement may be used employing only two colour-filters and one shutter; also the opening in the box may be only partly filled by the colour-filters, a certain amount of unfiltered light being transmitted. The light passes from the opening along a tube to a diffusing screen.—B. V. S.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

COMPLETE SPECIFICATION ACCEPTED.

8234 (1917). Pozzo and Colonnetti. *See* X.

I.—GENERAL ; PLANT ; MACHINERY.

PATENTS.

Drying apparatus. S. H. Melhuizen, Veendam, Holland. Eng. Pat. 114,620, Feb. 20, 1918. (Appl. No. 3035 of 1918.) Under Int. Conv., Mar. 31, 1917.

The material to be dried is placed in small cups which are arranged one above the other on platforms of slightly greater diameter than the cups. Baffle-plates perforated in the centre are arranged over the cups. The whole framework may be lowered into a vertical heating tube closed at the bottom, which is surrounded by a larger concentric tube containing a heating liquid. Air previously dried by passing it through sulphuric acid is supplied to the bottom of the inner tube, and is made to pass over the material in the cups by the baffles. A suitable heating burner is placed below the double tube and a third tube surrounds the heating tube for a portion of its height to maintain the hot combustion gases in contact with the walls of the heating tube. The two inner tubes are extended vertically for some distance above the material to be dried, the upper annular space being filled with suitable material to facilitate condensation of the vapour and its return to the heater. The top of the annular chamber may be connected to a vertical tube dipping into mercury to any desired depth, so that the pressure at which the liquid boils may be regulated. A large air vessel is connected to the system to receive air which is displaced by the vapour generated, and a mercury manometer is also provided. The apparatus is intended for drying amylum or similar materials, for the purpose of determining their moisture content for example.—W. F. F.

Drying installations. J. Schlatter and R. Frorath, Zurich. Eng. Pat. 115,193, Nov. 5, 1917. (Appl. No. 16,135 of 1917.)

In a drying apparatus for fruit, vegetables, cosmetics, chemical products, dyes, etc., hot gases and cold air are passed into the passages, 6 and

7 respectively, shown in cross-section in the figure, and a number of drying chambers, of which one, X, is shown, are arranged on both sides of the passages. The partition, 8, separating the passages, 6 and 7, terminates opposite a mixing chamber, 10, opening into the drying chamber, and the gases are finally discharged from the drying chamber into the conduit, 13. A balanced valve plate, 16, is arranged so that hot gas alone may be supplied by the openings, 20, 21. On lowering the plate, the opening, 20, may be cut off, and mixed hot gas and cold air supplied to the chamber, 10, in any desired proportions, or the hot gas may be completely cut off and cold air only supplied from the passage, 7. The

hot gas is obtained from a furnace through which air and combustion gases are drawn in regulable quantities by a fan. The furnace is surrounded by a cylindrical casing through which air can be drawn to mix with the hot

gases, and the mixture is discharged through a spiral conduit by a fan placed eccentrically in the casing. The passages, 6 and 7, may alternatively be supplied by a single blower, and a furnace may be arranged in the conduit leading to the passage, 6.—W. F. F.

Drying drum; Internally heated —. P. Frank, Charlottenburg, A. Frank, Berlin-Halensee, and M. Lebrun, Frankfurt on the Oder. Ger. Pat. 302,708, May 30, 1915.

The heating element consists of a drum through which hot gases flow. Inside the drum is fixed concentrically a second cylinder which causes the gases to flow over the inner surface of the outer one. The inner cylinder is filled with material capable of acting as a heat-accumulator and thus more uniform heating is attained.—H. J. H.

High temperature reactions; Methods of and furnaces or apparatus for conducting —. N. Testrup, and Techno-Chemical Laboratories, London. Eng. Pat. 115,087, Apr. 25, 1917. (Appl. No. 5829 of 1917.)

In apparatus for conducting high temperature reactions continuously in which the material is passed in a continuous layer in front of the source of heat, the material is fed on to a travelling conveyor in a greater depth than that subsequently treated, so that when the conveyor travels below and close to the heating device, a recessed path is swept out in the material, leaving a deeper layer outside the walls of the heating device to seal the heated zone against cooler air. The heating apparatus consists of a horizontal chamber of refractory material, heated internally by gas burners, and having its floor composed of a slab of magnesite or the like to transmit heat to the material below. The side walls extend slightly below the magnesite slab into the material, leaving a narrow space between the slab and the material. After passing the heater the layer of material is given a downward inclination, and a cover plate attached to the heater extends parallel to and just above the layer. The clearance space is thus filled with highly heated gas which prevents the passage of cooler gas to the heating zone. An adjustable dividing plate is provided just beyond the cover plate to remove the upper treated layer from the untreated material, and a toothed roller is arranged just above the dividing plate to break up the material. The treated substance falls into a trough, from which it is removed by a screw conveyor, and the untreated substance falls into another trough from which it is transferred by a conveyor to a receptacle and then fed again to the travelling conveyor for re-heating. To prevent any reaction between the furnace walls and the hot material, the magnesite slab is made thicker at the edges so that it transmits less heat to the material at the part in contact with the walls.—W. F. F.

Generator for mixed steam and combustion products. A. Cornet and L. Humblet, Quaregnon, Belgium. Eng. Pat. 115,211, Jan. 8, 1918. (Appl. No. 472 of 1918.)

A hollow cylindrical body is provided with a curved extension at one end, and a mixture of liquid or gaseous hydrocarbon and air under pressure is fed to an axial burner at the other end. The flame strikes the curved walls and produces an intensely heated zone, and water is injected into this zone from a number of nozzles arranged round the cylindrical body. The hydrocarbon fuel is fed to the burner through a jacket surrounding it whereby

the fuel is heated or vaporised, and the water is passed to the nozzles through a jacket surrounding the combustion chamber. Any water which is not vaporised on leaving the nozzle flows through the curved extension of the combustion chamber, and is vaporised by the hot gases passing through this extension. A mixture of steam and combustion products of low temperature and high pressure, suitable for operating a steam engine or turbine, is obtained.—W. F. F.

Oil-gas and other gas furnaces. Burdons, Ltd., W. M. and M. M. Burdon, Bellshill, Lanark. Eng. Pat. 115,214, Jan. 17, 1918. (Appl. No. 966 of 1918.)

In a furnace heated by oil-gas or other gas under pressure, two perforated pipes are provided at the base of the furnace door from which cold air blasts are emitted to cool the escaping hot gases when the door is opened. A damper is also provided at the top of the furnace, which is connected by levers with the door-lifting mechanism, so that both are lifted simultaneously, thus reducing the gas pressure within the furnace. The valves for controlling the air blast are connected by suitable mechanism with the operating gear of the damper, so that both are operated simultaneously when the furnace door is opened.—W. F. F.

Crushing, granulating, or reducing to powder, stone, ore, and like materials; Machinery or apparatus for —. W. H. Baxter, Ltd., and W. H. Baxter, Leeds. Eng. Pat. 115,218, Feb. 7, 1918. (Appl. No. 2223 of 1918.)

A bed or frame is provided with a pair of fixed bearings supporting a crushing roller with concave periphery, and with a pair of bearings movable horizontally in slideways supporting the co-operating roller which has a convex periphery. Each of the movable bearings carries a horizontal rod which passes through a fixed vertical part of the bedplate. A helical spring supported between the vertical member and a collar on the rod presses the movable bearing towards the corresponding fixed bearing, whilst two weaker helical springs supported between the opposite side of the vertical member and a bridge-piece on the rod similarly press in the opposite direction to the first spring. A more uniform pressure of the rolls is thus obtained. The tension of the springs may be varied by adjusting the position of the abutments carried by the rod.—W. F. F.

Roller mill. T. Robinson & Son, Ltd., and C. J. Robinson, Rochdale, and J. W. Collins, Roker, Durham. Eng. Pat. 115,689, May 15, 1917. (Appl. No. 6975 of 1917.)

In a roller mill having rolls with spiral grooves for grinding grain or granular material, the grooves are spaced apart so as to leave a smooth part of width equal to that of a groove. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pat. 1891 of 1882.)—W. F. F.

Pumping liquids; Apparatus for —. A. H. Human, Gerrards Cross, Bucks, and Kestner Evaporator and Engineering Co., Ltd., London. Eng. Pat. 115,251. (Appl. Nos. 4538, Mar. 29, and 6036, Apr. 30, 1917.)

In a pulsometer pump for raising corrosive liquids, the chamber, K, is connected to a reservoir of low-pressure air or a vacuum pump, and with the loaded valve, N, open, liquid is raised from the container, F, to the vessel, A, till the float valve, A², reaches its seating, A¹. The pressure in K then

falls and the external air pressure acting on the piston, O, causes the valve, N, to close the opening, N¹, the piston valve, M, being simultaneously opened. High-pressure air entering the chamber, L, through a contracted opening in L¹ then acts on the liquid in the vessel, A, and forces it past the valve, E, into the reservoir, G. When the valve, A², reaches its seating, A¹, the air pressure above

it increases till the valve, Q, is lifted and the resulting air pressure in K opens the valve, N, when the cycle is repeated. In a modification, the balance piston, O, may be replaced by a valve opening outwards. In another modification, the valves, M and N, are combined into a single two-way valve which is operated at the proper intervals by a piston working in a cylinder and actuated by the high-pressure air. The admission and discharge of air are regulated by a relay device consisting of two connected piston valves working in a casing, one of them being subjected to the pressure in the chamber, A. The movements of the piston valves are controlled by a suitable wire-drawing or a dash-pot device. The valves periodically place one or other side of the piston in communication with the high-pressure air, and the other side with the exhaust.—W. F. F.

Power system and pump. J. Wilkinson, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,263,981, Apr. 23, 1918. Date of appl., Jan. 14, 1914.

In an internal combustion pump of the type in which the exploded charge acts directly on an oscillating column of liquid, the usual openings for the admission of fuel, air, and combustion gases are provided, and also for the admission and discharge of liquid. An air pressure accumulator is provided at the delivery end of the moving column to diminish pulsations in the flow. The admission and discharge valves are operated by a constant-speed electric motor, the circuit of which is opened

and closed by means controlled by the pressure of the air in the accumulator, and thus responsive to the demand on the pump. An auxiliary electrical device is also provided, acting on the valve-controlling device, by which it is ensured that the pump is stopped only at a definite predetermined point in its cycle of operations.—W. F. F.

Gaseous products of chemical reactions; Purifying and absorbing —. C. S. Roy, Chingford, and T. Morson & Son, Ltd., London. Eng. Pat. 115,311, June 2, 1917. (Appl. No. 7940 of 1917.)

The gases flow upwards through a tower in which they are washed and purified, and then pass from the upper end of the tower to an absorber having an upper and a lower series of baffle plates arranged alternately. The upper plates are inclined to the vertical and the lower ones are preferably vertical. Solvent liquor from a compartment in the upper part of the absorber flows down over the upper plates as a film, collects in the lower part of the absorber to a level below the lower ends of the upper plates, and is thence returned to the compartment in the upper part of the absorber. The lower part of the tower is also connected with the absorber by a passage provided with a gate-valve, so that when desired the gases may pass directly to the absorber without ascending the tower.—J. H. P.

Separating water and other matter from compressed air and other gases; Apparatus for —. C. E. Jeffcock and W. H. Yardley, Sheffield. Eng. Pat. 115,325, June 22, 1917. (Appl. No. 9015 of 1917.)

A CASING of decreasing cross-section from its inlet to its outlet end is divided into compartments by transverse partitions. Each partition has a central opening, and through these openings extends a metal strip twisted in spiral form to guide and impart a rotary motion to the air passing through the casing. The air inlet is of small sectional area compared with the sectional area of the adjacent part of the casing. Liquid separated from the air passes through holes in the lower part of the partitions and flows to a discharge opening.—J. H. P.

[*Fluid*] *meter; Calorimetric* —. A. Guillemin, and Comp. des Forges d'Audincourt et Dependances, Audincourt, France. Eng. Pat. 115,354, Aug. 23, 1917. (Appl. No. 12,102 of 1917.) Under Int. Conv., June 30, 1917.

In apparatus for the measurement of hot fluids, particularly hot water or steam, the fluid passes upwards through a tube fixed at the bottom but free to expand at the top. The upper end carries a projection which bears against a substantially horizontal lever pivoted at its centre, the projection being slightly on one side of the centre. The tube opens at the top into a flat horizontal chamber having two openings in its upper face controlled by slotted piston-valves operated by the two ends of the pivoted lever, so that when one is open the other is closed. The valve-operating device is so constructed that the sum of the two openings remains constant. The valves are fully open at 100° C. and 0° C. respectively. Each valve controls the admission into a conduit containing a volume meter, and the two conduits are combined into a single conduit beyond the meters. The total volume of flow is obtained by adding the readings of the two meters. If V_1 and V_2 are the readings of the high and low temperature meters in c.c., then the mean temperature over a period is given by $\frac{100 V_1}{V_1 + V_2}$ in the case of water and by $100 + \frac{100 V_1}{V_1 + V_2}$ for steam between 100° and 200° C. The number of

calories passing through is given by the product of the total quantity of water passing and the mean temperature, or more simply by 100 V_1 . The instantaneous temperature reading may be obtained by using the proportional expansion of the tube to operate an indicator through a toothed rack at one end of the lever. The mean rate of flow is calculated from the total volume and the time.

—W. F. F.

Wet filters, water coolers, humidifying apparatus and the like. A. B. Cleworth, Hollnwood, Lancs. Eng. Pat. 115,521, June 8, 1917. (Appl. No. 8219 of 1917.)

In apparatus for heating, cooling, moistening, cleaning, or otherwise treating air or gas with liquid, or for cooling water, oil, or other liquid with air, or for condensing vapour, of the type in which the gas is passed over rotating discs having their lower portions immersed in liquid, the discs are formed of expanded metal and are arranged in groups on the same or on different shafts which may rotate at the same or different speeds. The discs may be made in sections if desired. The discs are enclosed in a cylindrical casing, and the liquid for each group of discs may be in a separate compartment. Baffles may be provided so that the air or gas which is driven axially through the casing is made to pass through and not around the discs.—W. F. F.

Air and gas; Apparatus for treating and cooling —. Heenan and Froude, Ltd., and G. H. Walker, Manchester. Eng. Pat. 115,546, July 28, 1917. (Appl. No. 10,860 of 1917.)

In apparatus of the type in which air is passed through one or more drums formed of convolutions of cloth or other suitable material wound spirally or concentrically around a horizontal shaft, with distance pieces to separate the coils, the liquid is distributed to each drum by perforated pipes, weir plates, gutters, or the like arranged at the edges of the convolutions of the drum. The perforated pipes may be arranged radially from a central annular supply chamber mounted eccentrically on the shaft, or the liquid may be supplied at the outer ends of the radial pipes which are connected to a central eccentric discharge chamber. The pipes are thus moved over the edges of the convolutions during rotation. A rotary extractor may be provided to eliminate moisture from the treated air or gas.—W. F. F.

Air-filtering or washing apparatus. P. H. H. Jantzen, London. Eng. Pat. 115,609, Jan. 25, 1918. (Appl. No. 1449 of 1918.)

In an air-filtering or washing apparatus in which air is passed over wet plates, the plates are arranged vertically in groups, the plates of adjacent groups being oppositely inclined to the flow of the air. Grid-bars or distance strips are arranged between the top edges of the plates, and are slightly recessed over the greater part of their length so as to leave a narrow slit between them and the plates. The tops of each group of plates thus form the bottom of a reservoir, and the water passes through the slits and flows down in thin films over the plates. The plates are supported in slotted racks so that they may be easily lifted out.

—W. F. F.

Air-separator. G. S. Emerick, Philadelphia, Pa. U.S. Pat. 1,263,394, Apr. 23, 1918. Date of appl., Jan. 27, 1917.

The material to be separated is fed over the deflecting plate, 19, into the double conical vessel,

6, and passes downwards over the sloping side of that vessel to the inverted cone, 24. The two conical vessels are connected by an annular vessel, 37, communicating through its lower horizontal face with the outer casing, 2. Air is admitted to

this casing and passes upwards against the flow of material through the annular vessel, 37, and conical vessel, 6, to the outer vessel, 2, as shown by the arrows. The current of air may be regulated by an annular valve plate, 30, movable vertically by cables, 31, operated from outside by bars extending through the top of the outer casing so as to vary the air inlet.—W. F. F.

Separator [for oils]; Magnetic —. A. L. Hadley, Fort Wayne, Ind., Assignor to General Electric Co. U.S. Pat. 1,263,406, Apr. 23, 1918. Date of appl., Oct. 7, 1916.

An iron or steel tank is provided with a central vertical partition extending from the top nearly to the bottom, and carrying at its lower end a horizontal plate of smaller diameter than the tank. A similar plate is arranged parallel to the first and below it, so that any liquid passing from one compartment to the other must pass between the plates. A flat solenoid is arranged in the bottom of the tank below the lower plate so that a magnetic field is maintained between the plates. Oil to be cleaned is admitted to one of the compartments and withdrawn from the other.—W. F. F.

Kiln. H. R. Straight, Adel, Iowa. U.S. Pat. 1,263,620, Apr. 23, 1918. Date of appl., Sept. 25, 1916.

Gas is supplied from a drum through several small pipes which pass through the crown of the kiln. Each of these gas-pipes is surrounded by a larger one through which the air for the combustion of the gas is supplied.—A. B. S.

Evaporating liquids; Method and apparatus for —. W. T. Roofnagle, Glen Ridge, N.J., Assignor to Electro-Chemical Products Co., New York. U.S. Pat. 1,263,893, Apr. 23, 1918. Date of appl., Oct. 12, 1916.

In a method of evaporating liquids under vacuum, the system is constantly exhausted, and a regulated quantity of ionisable gas is admitted and subjected to an ionising influence. The ionising chamber comprises an outer metal casing, within which is a dielectric vessel containing a conducting liquid. A conduit passing through the dielectric vessel connects the evaporating chamber and the casing.

—J. H. P.

Extraction of solids; Continuous —. H. Eberhardt, Wolfenbüttel. Ger. Pat. 302,641, Feb. 8, 1916.

The material descends one or more cylinders containing screw conveyors, meeting a rising stream of solvent. The material collecting in the chamber below is raised by another screw conveyor through an inclined cylinder against a stream of fresh solvent and ejected above the surface. The whole apparatus is enclosed, so that volatile liquids can be handled.—H. J. H.

Centrifuge drum with a surrounding annular chamber. H. Stegmeyer, Charlottenburg. Ger. Pat. 302,876, Apr. 12, 1916.

The apparatus consists of a casting in the form of a truncated cone divided by a perforated diaphragm in the form of an inverted truncated cone. The liquid separated from the material treated collects in the annular lower chamber and can be returned to the upper chamber.—H. J. H.

Cooler for salt solutions and other liquids. Maschinenfabr. Thyssen und Co., Mülheim. Ger. Pat. 302,887, Feb. 12, 1916.

SOLUTIONS are cooled preparatory to crystallisation by being allowed to fall through air in a spray from nozzles which are heated, e.g., by a steam jacket—to prevent premature crystallisation of salts and stoppage of the plant.—H. J. H.

Oils, resins, waxes, etc., and hygroscopic substances; Conversion of — into dry products. R. Marcus, Frankfurt. Ger. Pat. 303,122, Feb. 20, 1914.

ARTIFICIALLY prepared magnesium silicate has a higher capacity for adsorption than silicic acid. Alone or with the latter in admixture with liquids and hygroscopic solids it gives dry powders.

—H. J. H.

Refrigerating machines; Method of working compression —. G. Döderlein. Ger. Pat. 304,077, Dec. 4, 1914.

DRY and moist vapours are separately withdrawn from the compressor and passed through an oil separator before entering the condenser. The compression may also be effected in stages, an oil separator being placed between each compressor and the condenser.—C. A. M.

Cooling water; Process for increasing the cooling action of —. W. Billig, Berlin-Friedenau. Ger. Pat. 304,078, Aug. 15, 1915.

GASES are removed from the cooling water, e.g., by filtration through a charcoal filter, and the loss of heat conductivity due to the formation of gas bubbles on the walls of the cooling apparatus is thus prevented.—C. A. M.

Crushing and pulverising machines. A. D. Furse and A. J. Neill, London. Eng. Pat. 115,542, July 13, 1917. (Appl. No. 10,150 of 1917.)

Ammonia compressor. G. Ferguson, Assignor to Apeldoornsche Maschinenfabriek en Metaalgietterij voorheen L. Landaal, Apeldoorn, Netherlands. U.S. Pat. 1,264,043, Apr. 23, 1918. Date of appl., Nov. 10, 1917.

Method of disposing of waste gases from chemical operations. Eng. Pat. 115,350. See V.

Method of treating finely-subdivided material. U.S. Pat. 1,263,082. See XIII.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Combustion; Calculation of the excess of air used in —. V. Hassreidler. Metall u. Erz, 1918, 15, 139–143.

When a volume, G , of producer gas is burned, the volume of air, L , required is not $R-G$ as commonly stated, but $R-G+c-d$, where R is the volume of products of combustion, and c the contraction and d the expansion due to combustion. For 1 vol. of each of the following gases, when dry, the respective values of c are:— C_2H_4 or C_2H_2 , 2.5; CH_4 or C_2H_6 , 2.0; H_2 or C_2H_2 , 1.5; CO , 0.5. When the volume of the moist products of combustion is taken, neither expansion nor contraction occurs in the combustion of methane and ethylene; hydrogen and acetylene contract 0.5 vol., and with ethane and benzene an expansion ($d=0.5$) occurs. Again, if L_0 = the volume of air theoretically necessary and L the excess of air admitted, $L_0 = R-L-G+c-d$. This equation is applicable to moist flue gases if the volume of the water-vapour in them is taken into consideration. On the customary

assumption that $L=R-G$, the ratio $\frac{L}{L_0}$ may have only half its proper value. If E = the percentage of air in excess of that theoretically necessary, x = the excess of oxygen in the products of combustion, X = the volume of oxygen theoretically required for the combustion, and R = the volume of products of combustion, $E = \frac{100 Rx}{X}$. Fischer's ratio,

$$\frac{21}{21-79\frac{o}{n}} : 1 \quad (\text{where } o = \% \text{ oxygen and } n = \% \text{ nitrogen in the products of combustion}),$$

is applicable to coal, coke, and illuminating gas, but not to producer gas and other fuels containing a considerable percentage of nitrogen. Further, it is not satisfactory to use the percentage of nitrogen in the products of combustion as a basis for calculating the excess of air present, as a variation of 10% in the latter causes a variation of only 0.1% in the nitrogen, but a variation of 8% in the free oxygen.—A. B. S.

Wood; Carbonisation of — in inclined retorts at Värta gasworks, Stockholm. A. Molin. J. Gasbeleucht., 1918, 61, 50–53.

NEARLY one-half of the gas supply of Stockholm is now manufactured from wood carbonised in inclined retorts. To reduce the excessive proportion of carbon dioxide in the gas from wood, it is arranged that the lower half of the retort should always contain hot charcoal over which the gas passes on its way to the exit. A portion of the carbon dioxide is thereby converted into monoxide, but owing to the violent evolution of the gas in the early stages, much carbon dioxide passes unchanged. On discharging the retort one-half of the charge is left in the lower end. Fresh wood is piled above that and on top coal equal to one-tenth of the weight of wood. Coal is included to furnish hydrocarbons which on decomposition deposit carbon and so keep the retorts gas-tight, and also so that the ammonia liberated shall neutralise any acetic acid which may pass the hot charcoal undecomposed. The aqueous distillate is alkaline. The make of gas is at least 600 cub.

metres per ton, of calorific value 3000–3300 kilocalories per cubic metre. 50 kilos. of wood is charged every 2 hours, and the output of gas is approximately the same as that obtained when coal is carbonised, although the calorific value and the amount of useful coke produced are lower. The coke and charcoal mixture has been successfully used as fuel in gas producers.—H. J. II.

Olefines; Action of concentrated sulphuric acid on — with particular reference to the refining of petroleum distillates. B. T. Brooks and I. Humphrey. J. Amer. Chem. Soc., 1918, 40, 822–856.

The principal results of the action of sulphuric acid on olefines are polymerisation and the formation of secondary and tertiary alcohols, and of alkyl hydrogen and dialkyl sulphates; no simple mono-olefine appears to yield "tar" with sulphuric acid at below 15°C. With olefines of higher molecular weight the tendency is mainly to polymerisation with formation of hydrocarbons containing at least one double bond, which are relatively resistant towards sulphuric acid. During the refining of petroleum oils by treatment with sulphuric acid it is therefore probable that the treated oil contains the viscous polymerides and that these do not pass into the acid; contrary to the usually accepted view that the refined viscous petroleum oils of the lubricant type consist exclusively of naphthenes and polynaphthenes, it is consequently likely that they contain a considerable proportion of unsaturated hydrocarbons formed by the polymerisation of simpler olefines, and this view receives confirmation from the appreciable iodine value of such refined oils and from the fact that polymerides prepared by the action of sulphuric acid on definite olefines such as duodecene are very closely similar to lubricating oils of the same molecular weight. In the refining of petroleum distillates, tars are apparently not formed from the mono-ethylenic hydrocarbons but from diolefines, the presence of which is due to the high temperature of the previous distillation. The saturated paraffin hydrocarbons are not attacked by ordinary sulphuric acid although their sulphonation can be effected by fuming sulphuric acid. When gasoline or other hydrocarbon fractions have been refined by treatment with sulphuric acid, they may contain a small percentage of dissolved normal alkyl sulphates and a considerable quantity of polymerised olefines, so that the "keeping" and "drying" qualities may be impaired and re-distillation is necessary to remove these impurities which are introduced during the refining. The unpleasant odour of "cracked" gasolines is due to sulphur compounds and nitrogen bases, whilst the resinification observed on prolonged storage is probably due to diolefines; in these cases "sweet" and stable gasoline can be obtained by treatment with less than 6% by weight of 85–90% sulphuric acid followed by washing with alkali and re-distillation. In the refining of crude benzols the distillation after the sulphuric acid treatment is accompanied by the liberation of sulphur dioxide and the formation of a residue of high-boiling viscous oils which becomes converted into pitch or resin on longer heating; the sulphur dioxide arises from the decomposition of dissolved normal alkyl sulphates whilst the pitch or resin, often erroneously described as "coumarone resin," probably consists of or arises from the highly polymerised products derived from the diolefinic constituents of the crude liquid. As an outcome of the results obtained in this and previous investigations, the conclusion is drawn that at present there is no method for the quantitative determination of the volume percentage of unsaturated hydrocarbons in petroleum oils. (See also J. Chem. Soc., 1918, i., 286.)—D. F. T.

Paraffin wax; Oxidation products of —. M. Bergmann. Z. angew. Chem., 1918, 31, 69—70.

REFINED white paraffin wax, m. pt. 52°C ., of Galician origin was oxidised by blowing through it a rapid current of air at 130° — 135°C . for 15—18 days. The product was a brown, unctuous mass, with acid value 132, forming soaps with alkalis. The acid products were separated as barium salts and fractionated by distillation under reduced pressure after liberation by hydrochloric acid. The fraction distilling from 270° to 310°C . under 100 mm. pressure was further purified and identified by its m. pt., 80.1°C ., and by that of its ethyl ester, 55°C ., as lignoceric acid, which occurs in arachis oil and beech-wood paraffin. From the fraction distilling between 230° and 270°C . were isolated a neutral body, m. pt. 48°C ., crystallising in leaflets, an acid, $\text{C}_{11}\text{H}_{22}\text{O}_2$, m. pt. 53.7°C ., and another acid, m. pt. 38.4°C ., which might be an isopalmitic acid, $\text{C}_{16}\text{H}_{32}\text{O}_2$. (See also J. Chem. Soc., 1918, i., 285.)—J. F. B.

Effect of load on refractoriness of firebricks, etc. Mellor and Emery. Report of Refractory Materials Research Committee of Inst. Gas Engineers. See VIII.

PATENTS.

Coking ovens; Horizontal —. Soc. Franco-Belge de Fours à Coke, Brussels. Eng. Pat. 113,779, Nov. 9, 1917. (Appl. No. 16,469 of 1917.) Under Int. Conv., Feb. 26, 1917.

THE oven is divided transversely into two substantially symmetrical parts heated independently, and the space below each half is divided by a partition into two similar independent recuperators. Producer gas is passed through one of these recuperators from bottom to top and thence to the burner at the base of the combustion chamber, and air is similarly passed through the other recuperator to the burner. Combustion products pass from the top of the vertical heating flues into a horizontal passage and thence downwards through vertical conduits to the two recuperators through which they pass in zig-zag paths to pre-heat the gas and air. No reversal of the gas, air, and combustion products is necessary.

—W. F. F.

Gas generators; Method for operating — [with recovery of ammonium chloride]. A. Riedel, Kössern, Saxony. Eng. Pat. 101,220, Aug. 16, 1916. (Appl. No. 11,575 of 1916.) Under Int. Conv., Aug. 16, 1915.

IN the normal working of a gas producer, chlorides such as common salt, calcium or manganese chlorides or the like, are added, together with water, the amount of chlorine in the salt being equivalent to the nitrogen content of the coal. The whole of the nitrogen is thereby converted into ammonium chloride, which is recovered by condensation.—W. F. F.

Gasifying retort. H. R. Wemple, Elizabeth, N.J. U.S. Pat. 1,262,886, Apr. 16, 1918. Date of appl., Apr. 6, 1917.

A CUP-SHAPED member, 3, has its open end mounted on the intake, 1, of an engine and is provided with

a nozzle, 5, fixed at the top as shown. A cap, 8, fits over the member, 3, and fuel to be gasified passes through the opening, 13, and helical groove, 6, to the top of the nozzle, 5.—W. F. F.

Gas producer. F. Siemens, Berlin. Ger. Pats. (a) 303,062, Apr. 24, 1917, and (b) 303,562, May 10, 1917.

(A) IN addition to the usual gas outlet the producer is provided with two openings in the lower part, through one of which a highly heated gas is introduced to decompose the fuel, whilst through the other a portion of the gas produced is withdrawn for the preliminary heating of the gas used for the decomposition. These openings are connected with regenerators, one of which is used for heating the gas used for the decomposition, whilst the other is heated by the combustion of the gas withdrawn from the producer. The regenerators are so arranged that heat can be conducted to the fuel in the producer through one of the walls of the regenerators or of the flues leading thereto. The gas withdrawn for heating purposes is preferably taken from a place in the producer where the temperature is high, but where tarry compounds are not formed. (B) By far the greater portion of the producer gas is passed to the regenerator as described under (A), only a small portion, sufficient to ensure decomposition of the fuel in the producer, being withdrawn through the usual gas outlet.

—C. A. M.

Methane; Preparation of —. Badische Anilin u. Soda Fabrik. Ger. Pat. 303,718, Sep. 12, 1914. Addition to Ger. Pat. 292,615.

NICKEL catalysts as claimed in the original patent (see Fr. Pat. 463,114 of 1913; this J., 1914, 313) and also as prepared by impregnating substrata with relatively small amounts of nickel salt solutions free from halogens and sulphur (Ger. Pat. 297,258; this J., 1917, 873) are used for the preparation of methane at temperatures not materially exceeding 450°C . and avoiding a large excess of steam. This enables water-gas or other gaseous mixture containing carbon monoxide to be used in place of carbon monoxide.—C. A. M.

Tarry substances such as pitch or steel works tar and tar oils; Process for the fractional separation of — from superheated crude gases H., G., and E. Feld, Linz. Ger. Pat. 303,195, Oct. 12, 1913.

HOT water at or above the temperature of the "dew point" of the gas for steam is sprayed into the gas in such limited quantity that the temperature is reduced only to the point necessary for the separation of the desired tarry product. The receivers into which the gases pass from the retort may also be washed with water at or above the temperature of the "dew point" for steam. A thermostat may be used in which the gases and the water rise concentrically about the entrance tube, where they are again heated before leaving the thermostat. By repeatedly passing the washing agents used for washing the tar constituents of high boiling point through the gas-washing apparatus tar fractions of definite uniform composition may be obtained.—C. A. M.

Liquid fuel. H. Shannon, Richmond, Surrey, Assignee of W. P. Bending, San Francisco, Cal., U.S.A. Eng. Pat. 114,411, Sep. 7, 1917. (Appl. No. 12,856 of 1917.) Under Int. Conv., Mar. 27, 1917.

A SUITABLE quantity of animal fat or grease is added to a mixture of approximately equal volumes of

hydrocarbon oil and water, previously heated to a temperature sufficient to melt the added fat, and the whole agitated to form an emulsion. The mixture is suitable for use as a liquid fuel.

—T. St.

Distillate of shale free from sulphur; Process for obtaining a —. G. E. Heyl, London. Eng. Pat. 115,452, Sep. 14, 1917. (Appl. No. 4249 of 1917.)

The shale is finely ground with sufficient ferrous or ferric chloride to combine with all the sulphur contained in the shale, and the mixture distilled. It is claimed that practically all the sulphur is retained as iron sulphide.—T. St.

Motor fuels and light paraffin oils; Method of obtaining — from shale; and benzene, toluene and solvent naphtha from coal. P. M. Justice, London. From S. G. Pirani, Melbourne, Australia. Eng. Pat. 115,573, Sep. 19, 1917. (Appl. No. 13,485 of 1917.)

SHALE or coal in the form of coarse powder is mixed with a finely ground material, such as limestone, which under the action of heat will give off carbon dioxide, and with small iron scrap, or its chemical equivalent, and the mixture is slowly heated in a vertical retort to temperatures ranging from 175° to 800° C. according to the oils required. Shale may also be treated in the form of small lumps, when it is desired to obtain a coke ready for market without further treatment. The carbon dioxide given off during the distillation acts as a carrier for the hydrocarbon vapours evolved from the shale or coal, and prevents them from becoming permanently fixed gases, while the action of the iron scrap increases the volume of hydrocarbon vapours given off in the retort. The proportions of the ingredients vary according to the amount of oxygen contained in the coal or shale. With an oxygen content of 6 to 13% a suitable amount of limestone is 3 to 8%, and of iron scrap 1½ to 4%. When no more vapours are evolved the temperature is raised beyond 800° C. and water in the form of a fine mist or jet is injected into the lower part of the retort. The vapours formed in the two operations are passed through a condenser, and any uncondensed vapours are then passed through an absorbing tower containing coke which has been saturated with a suitable non-volatile oil. The condensed oils are separated by fractional distillation. The residual oils from the various distillations may be mixed with fresh quantities of limestone and iron scrap and subjected again to distillation. The vapours formed in this operation are however passed through a second retort exactly like the first, and at the same temperature, but charged to about half its capacity with manganese dioxide and iron scrap, preferably in the proportions of 1 part of the former to 2 parts of the latter. The effect of these last-mentioned materials is to enhance the production of condensable vapours.—T. St.

Oil; Recovery of — from oil-sands. F. Squires, Marietta, Assignor to W. Squires, Jamesville, Ohio. U.S. Pat. 1,263,618, Apr. 23, 1918. Date of appl., Jan. 26, 1918.

A GASEOUS medium is caused to pass through the oil-sand towards the pumping well, where the oil vapour carried by the gas is condensed. The oil is pumped from the well and the gaseous medium allowed to escape upwards through the well, a counter-current of oil supplied from the top of the well absorbing any remaining uncondensed vapour.

—L. A. C.

Sludge acid [from mineral oil refining]; Concentration and purification of —. W. A. Slater, Fort Worth, Tex., Assignor to Gulf Refining Co., Pittsburgh, Pa. U.S. Pat. 1,263,950, Apr. 23, 1918. Date of appl., May 18, 1917.

Acid sludge is treated with dilute acid and the weak acid is separated and concentrated by causing it to flow against a counter-current of heated air which has been blown through a body of previously concentrated acid in order to concentrate it further and to oxidise impurities therein. The air is finally scrubbed with water to furnish the dilute acid for the initial treatment of the sludge.

—L. A. C.

[Gas] retorts; Construction of vertical —. H. J. Toogood, and R. Dempster and Sons, Ltd., Elland. Eng. Pat. 115,738, July 16, 1917. (Appl. No. 10,282 of 1917.)

Oil-gas and other gas furnaces. Eng. Pat. 115,214. See I.

Magnetic separator [for oils]. U.S. Pat. 1,263,406. See I.

Method and plant for the distillation of tar, crude petroleum, resin, and similar materials. Ger. Pat. 302,323. See III.

Oil-tester [for determining the flash-point]. U.S. Pat. 1,263,145. See XXIII.

IIB.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Carbonisation and distillation of peat, sawdust, sweepings and other waste organic matter. C. Galaine and C. Houbert. Comptes rend., 1918, 166, 854—856.

Six cylindrical rotating retorts are mounted on separate shafts on a frame which enables the retorts to be heated in turn in a fixed semi-circular furnace. Three retorts are heated simultaneously, whilst one is cooling, one being emptied, and one being filled at the same time. With retorts each containing 1 ton of peat and rotating 10 times per min., the distillation requires about 40 min. The gas passes away through a hollow shaft in each retort to a central collecting flue in the main shaft of the frame. The by-products are treated in the customary manner for the recovery of ammonia, etc. By the rotation of the retorts, combined with the large surface exposed to the heat, rapid transmission of heat through them is attained, and hence the distillation can be carried out at a lower furnace temperature than in other apparatus. It is suggested that this arrangement should be used for the destructive distillation of household refuse.

—A. B. S.

Incandescence lamps; Crystals in filament form as used in electric —. F. Schröter. J. Gasbeleucht., 1918, 61, 44—45.

The effect of work on a tungsten filament is to convert the metal into the labile elastic form which reverts to the crystalline at high temperatures. Crystal boundaries are produced which are points of weakness and readily fracture. In the process of J. Pintsch (Fr. Pat. 469,212 and Ger. Pat. 304,857; this J., 1915, 36; 1918, 331 A) this is avoided by producing a filament consisting of one homogeneous elastic crystal. A drawn and sintered

thread is made of tungsten with the addition of 2% of thorium oxide which acts as a catalyst, and its micro-structure is found to resemble a bundle of crystals of octagonal section. The filament is drawn through a cylindrical electrically heated furnace with a zone at 2400°–2600° C. and an atmosphere of hydrogen. The rate of motion—about 2.5 metres per hour—is somewhat slower than that of crystal growth. The crystals, already existing, grow and coalesce so that at the end the whole filament consists of one crystal, which cannot therefore grow on further heating or develop new crystal junctions. The filaments show a high degree of pliability which is very permanent in use. —H. J. H.

Manufacture of paper pulp, etc., from dead leaves.
Bramson. See V.

PATENT.

Seal for retorts in distillation plants. W. Schacht, Weissenfels. Ger. Pat. 302,754, Aug. 26, 1916.

THE lid of a retort used for the dry distillation of residues of cellulose factories may be sealed with a metal or alloy liquid at the temperature of distillation. Up to 500° C. loss by volatilisation is negligible. An outer seal of high-boiling oil may be provided in addition to the seal of molten metal. —H. J. H.

III.—TAR AND TAR PRODUCTS.

Toluol [and cumene] from spruce turpentine. A. S. Wheeler. J. Ind. Eng. Chem., 1918, 10, 359–360.

SPRUCE turpentine (see this J., 1918, 296 A) was purified by distillation in superheated steam, the vapour being passed through 10% caustic soda and then condensed. The oil was separated from water, shaken with 0.5% potassium permanganate and then with strong sulphuric acid. The colourless purified oil, consisting mainly of cymene, was mixed with benzol 10 parts by weight and aluminium chloride 0.05 part by weight and boiled for 10 hours on a water-bath, the solution becoming dark red. The product was fractionated with a 3-section Young still head, and the portion distilling at 83°–95° C. was redistilled. Accumulations occurred at about 110° and 153° C., the boiling points of toluene and cumene. The cumene may be utilised by direct oxidation to benzoic acid.—W. F. F.

Action of concentrated sulphuric acid on olefines with particular reference to the refining of petroleum distillates. Brooks and Humphrey. See IIa.

PATENTS.

Distillation of tar, crude petroleum, resin, and similar materials; Method and plant for the —. T. Weickel, Weinsheim Customs House. Ger. Pat. 302,323, Jan. 16, 1917.

HORIZONTAL stills for tar distillation, etc., need not be walled in if the fire gases approach and leave at the same region.—J. C. W.

Method of obtaining motor fuels and light paraffin oils from shale, and benzene, toluene, and solvent naphtha from coal. Eng. Pat. 115,573. See IIa.

Concentration and purification of sludge acid.
U.S. Pat. 1,263,950. See IIa.

Process for the fractional separation of tarry substances such as pitch or steel-works tar and tar oils from superheated crude gases. Ger. Pat. 303,195. See IIa.

IV.—COLOURING MATTERS AND DYES.

Pyranthridone. R. Scholl and O. Dischendorfer. Ber., 1918, 51, 441–452.

The synthesis of pyranthridone,

which is intermediate between pyranthrone, $C_{20}H_{14}O_2$, and flavanthrene, $C_{22}H_{12}O_2N_2$, is described. The substance sublimes without melting in brownish-yellow needles, and forms a violet-blue hydrosulphite vat from which cotton is dyed orange-red, after hanging in the air. The parent base, pyranthridine, $C_{22}H_{17}N$, is also described. (See further J. Chem. Soc., 1918, I., 307.)—J. C. W.

Flavanthrene; Synthesis of —. R. Scholl and O. Dischendorfer. Ber., 1918, 51, 452–453.

THE immediate precursor of flavanthrene in various syntheses is 2,2'-diamino-1,1'-dianthraquinonyl. This has now been isolated for the first time, in microscopic, red needles, which change into flavanthrene at 250° C. (See further J. Chem. Soc., 1918, I., 308.)—J. C. W.

Rhoduline; The simplest —. F. Kehrmann and M. Ramm. Ber., 1918, 51, 385–388.

WHEN 3,7-diacetylaminophenazine is heated with methyl sulphate and nitrobenzene, a mixture of three methyl derivatives is formed, from which it is possible to obtain 3,7-diamino-5-methylphenazine in the form of salts. The solution of the perchlorate in concentrated sulphuric acid is green but becomes violet-blue and then red on dilution with water. (See further J. Chem. Soc., 1918, I., 313.)—J. C. W.

Phencyazonium compounds. F. Kehrmann and M. Sandoz. Ber., 1918, 51, 388–391.

WHEN a warm solution of Kaufmann and Albertini's 5-cyano-10-methyldihydroacridine (Ber., 1909, 42, 1909) in glacial acetic acid is exposed to the air, it becomes deep yellow owing to oxidation to 5-cyano-10-methylacridinium acetate. The corresponding crystalline perchlorate may be isolated. The base is now designated 10-methylphenacyazonium as it greatly resembles phenazonium as a chromogen. It may be regarded as the parent of Ehrlich and Benda's tryptaflavine (this J., 1913, 745. See further J. Chem. Soc., 1918, I., 313). —J. C. W.

Constitution and colour. VI. Triphenylmethane dyes. F. Kehrmann. Ber., 1918, 51, 468–474.

It is suggested that triphenylmethane bases form salts in strongly acid solutions in which the acid residues are attached not only in the usual way, as in solutions in more dilute acids, but also to the central carbon atom, by the exercise of a fifth and sixth valency or by residual affinity. (See further J. Chem. Soc., 1918, I., 311.)—J. C. W.

Jellies formed by dyes. R. Haller. *Kolloid Zelts.*, 1918, 22, 49—53.

WHEN certain substantive dyes are dissolved in hot water, solutions are obtained which form jellies on cooling. The structure of the jellies formed by Benzopurpurin B and Chrysophenin B has been examined and found to be very similar to that of the soap jellies investigated by Zsigmondy and Bachmann (this J., 1912, 1084). The formation of the jellies seems to be dependent on the presence of small quantities of electrolyte in the dyes, for when the solutions are purified by dialysis, coagulation takes place and the gelatinous coagulum is no longer soluble even in hot water. The addition of sodium chloride is however sufficient to bring the dye into solution. If the purified gelatinous coagulum is dried and powdered, the product resembles closely the original material but is sharply distinguished from this by its insolubility in hot water. The experiments show that the small quantities of electrolytes (sulphates and chlorides) which are present in the commercial substantive dyes are of very important significance in the technical application of these substances, but as yet no satisfactory explanation of the phenomena can be given. (Compare *J. Chem. Soc.*, July, 1918.) —H. M. D.

PATENTS.

Vat dyestuffs of the carbazole-naphthoquinone series; Manufacture of —. M. P. Schmidt, Assignor to Kalle und Co., Biebrich, Germany. U.S. Pat. 1,261,858, Apr. 9, 1918. Date of appl., Apr. 28, 1916.

CARBAZOLE-NAPHTHOQUINONES are condensed with compounds containing reactive hydrogen atoms, capable of condensation with a benzo- or naphthoquinone, giving brown to black powders, insoluble in water, sparingly soluble in the common organic media, and forming yellow to brown vats with alkaline reducing agents, from which fibres are dyed brown to black tints. The condensation products of carbazole-naphthoquinone (including toluencarbazole-naphthoquinone) with oxythionaphthene dissolve in concentrated sulphuric acid with greenish-blue colours, form yellow vats, and dye wool violet-black tints, the shades becoming redder on treatment with hot acids.—J. C. W.

Vat dyes of the anthracene series; Manufacture of nitrogenous —. Chem. Fabr. Griesheim-Elektron. Ger. Pat. 302,259, Dec. 22, 1914. Addition to Ger. Pat. 301,554 (see Eng. Pat. 14,103 of 1915; this J., 1916, 1104).

THE alkali salts of the partially alkylated dyes mentioned in the chief patent are alkylated further, different alkyl groups being introduced.—J. C. W.

Vat dyestuff of the anthracene series; Manufacture of a golden-orange —. Chem. Fabr. Griesheim-Elektron. Ger. Pat. 302,260, June 6, 1916.

THE benzyl derivative of Pyrazole-anthrone Yellow (Eng. Pat. 14,103 of 1915; this J., 1916, 1104) is warmed with sulphuric acid. The product gives a bluish olive green vat which dyes cotton fast golden orange.—J. C. W.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Cellulose of cereal straw; Nature of the —. E. Heuser and A. Haug. *Z. angew. Chem.*, 1918, 31, 99—100, 103—104.

IN the determination of cellulose in straw by the chlorine process the separation of the last residue of lignin presents some difficulty, and if the usual

sulphite solution be employed for extracting the chlorinated product, a large number of chlorine treatments is necessary, so that the cellulose is abnormally attacked. On the other hand, if a 10% solution of sodium hydroxide is used after each chlorination, a pure cellulose can be isolated in a reasonable time. According to the method recommended by the authors, 2 grms. of chopped straw (internodes) is placed in the Gooch crucible (see this J., 1914, 71) and treated with a strong current of steam for 10 mins. to soften the material. It is then thoroughly washed and treated with chlorine gas for half an hour. The hydrochloric acid produced is washed out, and the crucible placed in a beaker containing about 100 c.c. of 1% caustic soda solution which is heated for 10 mins. at a temperature not exceeding 70° C. The treatment with chlorine gas and caustic alkali is performed four times in all, for half an hour each time, and the cellulose is finally bleached with 0.1% permanganate. The yield of cellulose, calculated on the dry and ash-free basis, is 54.75—55.60%; the product is free from lignin and oxycellulose but still contains pentosans (furfuroids). In an example given, the amount of hydrochloric acid produced in the first four chlorinations of half an hour each was 28.5%; the total after 10 chlorinations was 32.34%. After 5 chlorinations, the amount of hydrochloric acid produced per treatment became constant (0.55—0.60%). The amount of chlorine combining with the lignin ranged from 9.50 to 10.81%. The action of the chlorine gas on the pentosans has been studied by the treatment of an isolated preparation of xylan. The quantity of hydrochloric acid produced after 4 hours' treatment with chlorine was 9.0% and after 15 hours, 16.9%, and the amount of chlorine fixed as xylan chloride was 16.8%. These figures suggest combination of the xylan with chlorine by substitution, but they cannot be regarded as final. This reaction is much slower than the reaction of chlorine with lignin, and only a small portion of the acid produced in the chlorination of straw can be attributed to the xylan. In the chlorination of straw, a portion of the xylan is hydrolysed in the initial treatment with chlorine and appears in the extract in the form of pentose. In the later treatments it is dissolved without hydrolysis.—J. F. B.

Wood pulp. C. G. Schwalbe. *Z. angew. Chem.*, 1918, 31, 50—56, 57—60.

COMMERCIAL wood pulps contain about the same quantity of cellulose, namely 91 to 92%. Mitscherlich pulp and Ritter-Kellner sulphite pulp contain the least quantity of pentosans, soda pulp the most. There is no great difference in the lignin content of the pulps. Sulphite pulps yield the most ether-extract (0.7%), whilst soda pulps give much less (0.2%). Half-stuff and three-quarter-stuff contain a considerable quantity of pentosans, and lignin or sugar, but there are, possibly, two kinds of half-stuff, the one rich in lignin and the other in pentosan. A true half-stuff, with a yield of 80 to 90%, might be prepared from half-stuff rich in pentosan but a suitable solvent or hydrolytic agent for the purpose is not yet known. The cell-length of pulp is about 2 to 3 mm., which is one-half the minimum length required for good spinning fibres; probably bundles of supple fibres provide the necessary length in the case of pulp. —W. P. S.

Wood pulp; Colour reaction of mechanical — *or of the incrusting substances of wood with phenylhydrazine hydrochloride.* S. Jentsch. *Z. angew. Chem.*, 1918, 31, 72.

THE lignocellulose of wood combines with phenylhydrazine hydrochloride in aqueous solution in

definite proportions capable of quantitative measurement. The orange-yellow compound so produced, when dried with free exposure to air, acquires a characteristic bright green colour which is more definite than the crimson coloration produced by phloroglucinol and hydrochloric acid. The development of the green coloration is hastened by heating, so that it may appear after a few seconds with great clearness. Pure cellulose fibres, on treatment with phenylhydrazine hydrochloride, are coloured only pale yellow and assume a characteristic light brown colour on drying. The phenylhydrazine reagent possesses several advantages over the strongly acid phloroglucinol reagent and is recommended as an indicator for the presence of woody fibre in paper and for the estimation of the degree of purification of cellulose fibres from lignified materials.—J. F. B.

Sorghum vulgare (millet); Use of — in the cellulose industry. B. Haas. Z. angew. Chem., 1918, 31, 84.

THE stems and branches of *Sorghum vulgare* are being extracted for the purpose of beer brewing. When treated like esparto the residue has been found to yield a fibre well adapted to the manufacture of paper and textile fabrics. The treatment is, however, simpler, the time of heating, steam pressure, and quantity of chemicals required all being smaller. The manufacture might be linked up with that of alcohol.—H. J. H.

Paper-pulp, etc.; Manufacture of — from dead leaves. K. Bramson. Comptes rend., 1918, 166, 853–854.

THE process is simple, rapid and not costly. The leaves are crushed and separated into two parts, i.e., the veins and ribs, and a powder. The veins and ribs, which yield the paper pulp, are submitted to a rapid washing with alkali, followed by washing with water and bleaching, and then made into pulp. The powder, which has a feeding value almost equal to that of hay, may be mixed with molasses and compressed into cakes and fed to animals. An alternative use for the powder is to submit it to dry distillation, when it yields a relatively pure, porous carbon, with a high calorific value, tar, acetone, and pyrolygneous acid. In this way 1000 kilos. of leaves yields 250 kilos. of paper pulp and 500 kilos. of fodder or 200 kilos. of carbon, 30 kilos. of tar, 1 kilo. of pyrolygneous acid, and 600 grms. of acetone.—W. G.

Artificial silk; Treatment of washing water in the production of —. M. de Chardonnet. Comptes rend., 1918, 166, 783.

IN the manufacture of artificial silk from a collodion base about 4 cubic metres of waste liquor is produced per kilo. of silk. The washings from the denitration partly neutralise the liquor obtained by washing the pyroxylin. The waste liquors contain per cubic metre: nitric acid, 0.650; sulphuric acid, 1.10; sulphur in a finely divided state, 0.175; calcium, 0.11 kilo.; the free acid being from 1 to 1.50 kilo. per cubic metre. The washings are conveyed through separate stoneware pipes to a small pond in which admixture takes place in a closed space so as to avoid a nuisance from the nitrous gases evolved on mixing. The partly neutralised liquor then passes over a weir into tanks in which neutralisation is completed by the addition of ground limestone or quicklime. It is unnecessary to clean out the tanks as sufficient water is always present to ensure complete solution of the calcium

nitrate and sulphate produced, and the finely divided sulphur remains in suspension. The neutralised liquor is said to be a good fertiliser.

—C. A. K.

Toluol [and cumene] from spruce turpentine. Wheeler. See III.

PATENTS.

Fabrics; Machine for drying — in open form. C. Taylor, West Nutley, N.J., U.S.A. Eng. Pat. 110,747, Oct. 6, 1917. (Appl. No. 14,474 of 1917.) Under Int. Conv., Oct. 21, 1916.

AN enclosed casing through which a drying medium, such as hot air, is circulated contains an endless travelling member with rollers for hanging the fabrics, and means are provided for rotating the rollers while they are carried through the casing by the travelling member. The fabric thus hangs without tension in festoons and receives a vertical travelling motion through the rotation of the rollers as well as a horizontal motion forward with the rollers. The lower portions of the loops of fabric are supported by a travelling platform which moves forward through the casing at the same speed as the rollers. Means are provided to guide the fabric on the rollers, and to draw the fabric into and deliver it out of the casing.—J. F. B.

Rice straw; Process of producing fibrous material from —. J. K. Toles, San Francisco, Cal. Assignor to Union Fibre Co., Winona, Minn. U.S. Pat. 1,262,872, Apr. 16, 1918. Date of appl., Dec. 20, 1915.

RICE straw is immersed in a "nominally weak" alkaline solution which is boiled for a sufficient time to dissolve the gummy substances surrounding the rice fibres without pulping or disintegrating them; the fibres are then freed from excess of gums and alkaline solution.—J. F. B.

Fibres; Process for obtaining textile —. A. Frohmader, Nürnberg. Ger. Pat. 301,283, Aug. 30, 1916.

GRASS-LIKE or herbaceous plants are treated with dilute caustic soda at the ordinary or a moderate temperature; the fibres are loosened by a gentle mechanical movement during or after steeping, then separated from the swollen or dissolved incrusting matters, washed, if necessary with further agitation, dried, and worked up in the ordinary manner.—J. F. B.

Wool; Process for testing the wearing quality of —. P. von Allwörden, Osterode. Ger. Pat. 302,808, Jan. 30, 1916.

WOOL is moistened with chlorine water and examined under the microscope in order to see whether the swellings, which are characteristic of good wool, appear under the scales. These swellings are due to the presence of "elastium" between the fibre cells and the epidermal scales, the removal of which in the scouring process makes the wool tender and brittle and incapable of fulling and finishing. (See also this J., 1916, 416; 1917, 706.)—J. F. B.

Fibres and textiles; Process for making woolly artificial —. P. Kraiss, Tübingen. Ger. Pat. 303,731, Mar. 29, 1917. Addition to Ger. Pat. 302,611.

PARCHMENTISED paper pulp is employed as a binding medium in the process described in the chief patent

(this J., 1918, 332 A). Parchment papers may be prepared containing 50% or more of wool; these are very strong and may be made pliable and water-resistant by suitable treatment and additions.

—J. F. B.

Waterproof [fibrous] composition and process for making such composition [from spent bark].

V. A. Wallin, Grand Rapids, Mich., and O. A. Heppes, La Grange, Ill. U.S. Pat. 1,263,823, Apr. 23, 1918. Date of appl., Mar. 6, 1917.

SPENT bark is finely divided crosswise of the grain into pieces so short as to be capable of saturation from end to end; the product is mixed with a fibre such as will afford tensile strength and the mass is felted together to form a sheet, to which a waterproofing material is intimately applied.—J. F. B.

Cellulose acetate and a process of making same.

F. Ruppert, Mainz-Mombach, Assignor to Verein für Chemische Industrie in Mainz, Frankfurt, Germany. U.S. Pat. 1,263,119, Apr. 16, 1918. Date of appl., Nov. 13, 1914.

CELLULOSE is treated with acetic anhydride or with acetic acid and anhydride, below 20° C., in presence of a metalloidal chloride as a catalyst but without the addition of a diluting agent, avoiding the solution of the reaction product, and the reaction is interrupted as soon as the mass forms an unliquefied jelly soluble in tetrachloroethane but insoluble in cold glacial acetic acid.—J. F. B.

Cellulose acetates; Process for the manufacture of masses or films of low melting point from infusible —. Verein für Chemische Industrie, Frankfurt. Ger. Pat. 303,018, Nov. 7, 1912.

CELLULOSE acetate is incorporated with triphenyl phosphate to form a homogeneous mass, which melts under the action of heat and falls away without bursting into flame.—J. F. B.

Viscous liquids; Process for spinning — with use of liquids in motion for drawing off the threads. J. P. Bemberg A.-G., Barmen-Rittershausen. Ger. Pat. 303,047, Aug. 26, 1916.

A MOVING liquid is used which is free from dissolved gases or from which these have been removed by evacuation, heating, or the like. (Compare Eng. Pat. 113,010 of 1917; this J., 1918, 146 A.) —J. F. B.

Plants; Process for treating parts of —. C. Melhardt, Starnberg. Ger. Pat. 303,730, Apr. 19, 1917.

PARTS of plants are treated for the separation of fibres, cellulose, or cell-contents, by steeping in dilute alkali solutions, with suitable additions to prevent putrefaction and fermentation, in pits from which air is excluded, until the soluble matters can be separated by washing or leaching and the insoluble matters by pressing.—J. F. B.

Sulphite pulp process; Reclaiming system in a —. C. B. Thorne, Hawkesbury, Ont., Canada. U.S. Pat. 1,263,486, Apr. 23, 1918. Date of appl., Nov. 22, 1913. Renewed, Sept. 22, 1917.

THE system comprises a number of acid-forming tanks, an acid receptacle, connected with a gas-generating plant, receiving liquor from the digester and delivering gases to the acid tanks, and a second receptacle receiving liquor from the acid receptacle and gases from the digester. The gases exhausted from the digester pass to a separator, the gas outlet

of which is connected with a recovery tower and the liquor outlet with an acid tower which in turn is connected with the recovery tower and with the acid-forming tanks, and means are provided for delivering the liquor from the tanks to the acid tower and from the latter to the recovery tower.

—J. F. B.

Waste gases from chemical operations [e.g., from the sulphate-cellulose process]; Method of disposing of —. A. G. Bloxam, London. From Zellstoff-fabrik Waldhof, Mannheim-Waldhof, Germany. Eng. Pat. 115,350, Aug. 10, 1917. (Appl. No. 11,539 of 1917.)

MALODOROUS waste gases, such as those produced in the manufacture of cellulose by the soda-sulphate process, are led directly into the primary air-intake of the gasifying chamber of a fuel gas producer. The gases are thus forced to pass through a relatively deep combustion zone and any small residue which escapes combustion is again subject to combustion when the fuel gas is burnt.

—J. F. B.

Impregnating material for leather, leather substitutes, fabrics, etc. Ger. Pat. 302,158. See XV.

Jellies formed by dyes. Haller. See IV.

Electrical endosmosc. II. Briggs and others. See XI.

PATENTS.

[Aniline] Black on vegetable fibres; Production of —. The Calico Printers' Association, Ltd., and E. A. Fourneaux, Manchester. Eng. Pat. 115,278, May 5, 1917. (Appl. No. 6114 of 1917.)

MIXTURES are used consisting of (a) aniline, (b) one or more primary amines of the benzene series, comprising the substitution products of aniline and their homologues, benzidine and its homologues and substitution products, but not diphenylamine compounds nor phenylenediamine, *p*-aminophenol and their homologues, (c) hydrochloric acid and/or nitric acid, (d) formic acid, which may be replaced to the extent of one-fifth by other carboxylic acids, (e) chlorates of the alkali metals, (f) one or more catalytic agents comprising copper and/or vanadium salts alone or in conjunction with *p*-phenylenediamine or *p*-aminophenol or their homologues, preferably in the form of hydrochlorides. Example: —Aniline, 39.5; aniline salt, 6.5; benzidine dihydrochloride, 20.5; *p*-phenylenediamine dihydrochloride, 1.75; formic acid (90%), 65; lactic acid (30%), 30; sodium chlorate, 28; copper chloride, 7.75; starch, 35; gum dragon mucilage, 150 parts by weight; water to 1000 parts by volume.—J. F. B.

Dyestuff pastes, solutions, and vats; Process for preparing —. S. Aschkenasi, Berlin. Ger. Pat. 303,121, Aug. 8, 1916.

THE so-called fat-splitting agents are used as additions to the dye-bath to produce emulsification. Neutral or acid hydrosulphite vats are prepared by adding to the ordinary alkaline vats, after reduction by hydrosulphite, a fat-splitting agent or its aqueous solution at a temperature not exceeding 40° C. In the case of indigo a fat-splitting agent, such as Twitchell's reagent, is added, in the

proportion of 1–3% of the dyestuff, and the mixture gives a homogeneous emulsion on stirring with water. This paste is stirred with concentrated alkali hydroxide and then reduced with hydro-sulphite; the product on dilution gives an alkaline vat.—J. F. B.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Hydrochloric acid from the waste liquors of the potash industry; Manufacture of —. B. Lepsius. *Z. angew. Chem.*, 1918, **31**, 93–95.

According to Hepke's process (Ger. Pat. 278,106; this J., 1915, 227) the final liquors from the German potash salt factories, containing magnesium chloride, are evaporated to about two-thirds of their bulk, mixed with 15% of crude magnesite, and the mass is allowed to set in moulds. The magnesium oxychloride is broken up and calcined in a gas-heated rotary tube furnace, 35 m. long. The maximum temperature required is 600° C. The products are crude magnesite, containing 80–90% MgO, and hydrochloric acid which is easily collected and condensed in long quartz pipes. The yield is 75% of the theoretical. The question whether this process, which is admittedly a practical one, is capable of solving the difficulty in connection with the disposal of the waste liquors and the contamination of the rivers with soluble chlorides, depends on the commercial outlets for the products. With regard to the magnesite, no fundamental difficulty is expected. The German iron industry consumed about 350,000 tons of magnesite annually, manufactured from magnesite imported from Greece; the use of magnesium oxychloride cements for making artificial wood plasters accounted for about 30,000 tons. With regard to the hydrochloric acid, the outlook is not favourable. The transport of this article limits its utility, as the centres of consumption are far removed from those of production. Leblanc hydrochloric acid will not be easily displaced, because the salt-cake is required for the glass industry. Whether hydrochloric acid can replace sulphuric acid for the absorption of ammonia from coke and gas ovens for agricultural purposes is not yet clear, but in any case the chlorides would ultimately find their way to the rivers and the situation would not be relieved. A large extension of the oxychloride cement industry would be favourable, but this product is not weather-proof and its utilisation cannot become sufficiently general.

—J. F. B.

Nitric acid; Apparatus for the determination of — by the Schulze-Tiemann method. K. Leuchs. *Chem.-Zeit.*, 1918, **42**, 235.

The apparatus described is constructed entirely of glass. The decomposition flask is provided with a glass stopper carrying a tap-funnel and a delivery tube, the stopper being surrounded by a water-seal. A non-return glass valve is fitted in the delivery tube midway between the flask and the gas burette. (See also *J. Chem. Soc.*, July, 1918.)—W. P. S.

Ammonia; Synthesis of — at high temperatures. H. E. B. Maxted. *Chem. Soc. Trans.*, 1918, **113**, 386–389.

In extension of the earlier investigation (compare this J., 1918, 105) it was found that by submitting a current of hydrogen (3 vols.) and nitrogen (1 vol.) inside a capillary glass tube to the action of an induction discharge modified so as to form a small high-tension arc, it is possible to obtain at atmospheric pressure a yield of ammonia amounting

to 1.5% of the gaseous mixture treated. The effect of induction sparks as such is feeble, and for the energetic production of ammonia it is necessary to bring the electrodes sufficiently close together to produce a small high-tension arc accompanied by a visible and apparently continuous flame of high temperature.—D. F. T.

Sulphur dioxide and ammonia; Oxidation of — in the presence of platinum and rhodium. P. Wenger and C. Urfer. *Ann. Chim. Analyt.*, 1918, **23**, 97–104.

When a mixture of sulphur dioxide and oxygen is passed over heated platinum black, maximum oxidation occurs at 432° C., 96.8% of the dioxide being converted into trioxide, whilst with rhodium black the maximum oxidation (91.1%) takes place at 610° C. Ammonia is oxidised to the extent of 97.7% by platinum black at 562° C., but the maximum conversion by rhodium black is only 69.7% at 662° C.; the products in both cases are nitrous and nitric acids.—W. P. S.

Potassium carbonate; Causticising —. E. Belloni. *Annali Chim. Appl.*, 1918, **9**, 115–149.

The method of preparing potassium hydroxide by treating potassium carbonate with lime, which prior to the war had been largely superseded by the electrolytic process, is again being used extensively, and in Italy potassium carbonate obtained by calcining molasses is treated by this method. Increasing the proportion of lime materially beyond the amount required to convert the potassium carbonate does not yield any increase in the proportion of alkali, and may cause a considerable loss. For example, in works where an excess of 140% of lime was used there was a loss of 25.65%. Provided there is efficient agitation of the mixtures, e.g., by means of steam, the reaction proceeds rapidly without excess of lime. Treatment of the potassium carbonate solution under pressure (3 to 4 atmos.), as claimed in several patents, has no influence upon the final reaction, although it enables the process to be effected at 125° to 150° C., and thus accelerates the velocity of reaction. The concentration of the potassium carbonate solution should not exceed 12%, in order that the quantity of unconverted potassium carbonate may not exceed 5%. The loss frequently noted in the process is to be attributed, not to the formation of a double carbonate of calcium and potassium, which cannot exist under the working conditions, but to the excess of calcium oxide generally used, which mechanically carries down and retains some of the alkali. Temperature has no influence on the conditions of equilibrium, at all events in solutions of medium concentration. The best results are obtained at 100° C., care being taken to keep the volume of the solution constant. Under these conditions the filtered product after concentration to 40° B. (sp. gr. 1.384) ought not to contain more than 1 to 1.5% of unaltered potassium carbonate. The chief impurities in potassium hydroxide prepared in this way are potassium carbonate, potassium chloride, and traces of silica, iron, and aluminium. If the solution at 40° B. (sp. gr. 1.384) be concentrated to 47° to 48° B. (sp. gr. 1.483–1.498) and cooled, crystals of the hydrate KOH.2H₂O mixed with part of the potassium carbonate are obtained, whilst the potassium chloride and other impurities remain in the mother liquors. As a rule, a single crystallisation is sufficient to remove the whole of the potassium chloride. The crystals are washed with a little water, dissolved in water, the solution treated with barium hydroxide to convert the potassium carbonate into hydroxide and filtered, and the filtrate concentrated in silver vessels. This new method gives better

results than the old method of purification with alcohol followed by treatment with barium hydroxide. (See also J. Chem. Soc., July, 1918.)

—C. A. M.

Mixtures of salts; Equilibria in solutions containing —. 1. *The system water and the sulphates and chlorides of sodium and potassium.* W. C. Blasdale. J. Ind. Eng. Chem., 1918, 10, 344–347.

The conditions which govern the separation by fractional crystallisation of potassium salts from other salts frequently associated with them were investigated by the aid of the phase rule diagrams for such solutions. The equilibrium conditions of the reversible reaction

were studied, and the compositions of the solutions saturated with one or more of these salts at 0°, 25°, 50°, 75°, and 100° C. were plotted with respect to four axes representing sodium sulphate, potassium sulphate, potassium chloride, and sodium chloride, the ordinates being in mols. of salt per 1000 mols. of water, for solutions saturated at the given temperatures with each of the constituents. The diagram for 25° C. is very similar to that previously given by Meyerhoffer (Z. physik. Chem., 1899, 28, 453) and the diagrams for 50°, 75°, and 100° C. are closely similar and differ from that for 25° C. in the way that would be expected from the known changes in the solubility of the four simple constituent salts. The diagrams indicate the composition of all possible solutions which can be in equilibrium with the six salts, sodium sulphate, sodium chloride, sodium potassium sulphate (glaserite), Glauber's salt, potassium chloride, and potassium sulphate. All these diagrams indicate a very large field representing the composition of the solution with which solid glaserite is in equilibrium. (See also J. Chem. Soc., July, 1918.)

—W. F. F.

Sodium and potassium chlorides and sulphates; Separation of — by fractional crystallisation. W. C. Blasdale. J. Ind. Eng. Chem., 1918, 10, 347–353.

The application of the principles described in the preceding abstract to the separation of mixed solutions is shown. As an example, illustrated by the diagram, the points D₁—D₅ represent the compositions of solutions saturated with sodium chloride at 0°, 25°, 50°, 75°, and 100° C., C₁—C₅ represent the composition of solutions saturated

with potassium chloride, and H₁—H₅ that of solutions saturated with both salts. The lines D₁ H₁, etc., represent solutions saturated with sodium chloride with varying amounts of potassium chloride, and C₁ H₁, etc., solutions saturated with potassium chloride with varying amounts of sodium chloride. If an unsaturated solution represented by p is evaporated at 100° C. it will become saturated

with sodium chloride at the point q, and this will be deposited till the saturation point, H₅, for potassium chloride is reached. On cooling to 0° C. potassium chloride only will separate till the point r is reached. If this is removed and the solution then evaporated at 100° C. sodium chloride will again separate when the point s is reached. This cycle may then be repeated. The results of working at other temperatures may also be calculated from the diagram, and the relative efficiencies compared. Similar diagrams are given for mixtures of potassium chloride and potassium sulphate, of potassium sulphate and sodium sulphate, of sodium sulphate and sodium chloride, and of sulphates and chlorides of sodium and potassium. These diagrams indicate possible cycles for the efficient commercial separation of the salts. The applications of the diagrams to the most efficient separation of potash from the ash of kelp and from a desert brine are given in detail. (See also J. Chem. Soc., July, 1918.)—W. F. F.

[Wood] ash leaching plant; Inexpensive —. W. D. Turner and B. G. Nichols. J. Ind. Eng. Chem., 1918, 10, 374–376.

A NUMBER of wooden buckets perforated at the bottom are arranged in tiers of six buckets, the uppermost being a water reservoir, and a non-perforated bucket being provided at the bottom for the liquor. The bottom of each bucket is covered with about 3 in. of "excelsior," and a layer of cloth, and the buckets are then filled with wood ashes. Water is allowed to drip from the reservoir till the ash in all the buckets is saturated, and a measured quantity of water equal to half the weight of ash in one bucket is then placed in the reservoir and allowed to drip through the column. An equivalent amount of liquor is forced out at the bottom and the ash and filters then removed from the top bucket and fresh ash substituted. This bucket is then placed at the bottom, the others being raised a step and water equal to 1.5 times the weight of ash placed in the reservoir and allowed to drip through. The operation is repeated as many times as desirable. The liquor, without concentrating, is boiled with the requisite amount of lime and allowed to settle. The lime mud is removed, and spread over the ash in the lowest bucket so that any soluble potash is subsequently leached out. The potash in the liquor may alternatively be converted directly to sulphate by the addition of sulphuric acid. The apparatus is simple, cheap, and rapid, and about 99% of the available potash is recovered.—W. F. F.

Carbon dioxide in carbonates; Determination of — by Dittrich's method. B. von Horvath. Chem.-Zeit., 1918, 42, 121.

In this method borax is heated at 1000° C., cooled, the carbonate is added, and the mixture re-heated at dull redness until evolution of carbon dioxide ceases; the loss in weight gives the amount of carbon dioxide present. The method is rapid and suitable for the determination of carbon dioxide in sodium carbonate and barium carbonate. Allowance must be made for any water or other volatile substance in the carbonate. (See also J. Chem. Soc., July, 1918.)—W. P. S.

Reactions between solid substances. L. H. Parker. Chem. Soc. Trans., 1918, 103, 396–409.

By investigating the velocity of reaction of barium sulphate, silver nitrate, and cuprous chloride respectively with sodium carbonate at different temperatures, it was found that at the point of fusion a marked increase is observable in the rate of reaction. This result indicates that the increased

reactivity of substances in the fused state is due to the existence of at least one of the reagents in the liquid state and is not merely a result of the high temperature necessary to cause fusion. The interaction of the ingredients of solid binary mixtures when these are submitted to shearing stress, *e.g.*, by means of a mortar and pestle (Parker, this J., 1914, 770), is therefore probably correctly attributed to local surface fusion of the reacting substances under the mechanical strain.

Sodium gold chloride; Adsorption of — by charcoal and the estimation of gold in sea water. H. Koch. *Kolloid Zeits.*, 1918, 22, 1—22.

GOLD is readily adsorbed from dilute solutions of gold chloride by various commercial forms of carbon. Experiments were made with animal charcoal, wood charcoal, coke, Indian ink, and lamp-black with results which show that adsorption occurs even when the quantities of gold in solution are extremely small. Results obtained with solutions of varying concentrations of gold chloride in 3% sodium chloride solution can be satisfactorily represented by means of the ordinary adsorption formula, and since wood charcoal was found to be the most suitable adsorbent, this material was employed in the experiments with sea water. Results obtained with samples of sea water from the Adriatic and the Riviera show that gold is present to the extent of 2.5 to 4 mgrms. per cubic metre. Although the author's results agree with those recorded by certain previous observers, it should be noted that gold concentrations of the order of 50 mgrms. of gold per cubic metre have been found by Liversidge. (Compare *J. Chem. Soc.*, July, 1918.)—H. M. D.

Thionyl and sulphuryl chlorides; Action of — on sulphur and phosphorus. H. B. North and J. C. Thomson. *J. Amer. Chem. Soc.*, 1918, 40, 774—777.

WHEN heated in a sealed tube at 150°—180° C. thionyl chloride reacts with sulphur in accordance with the equation: $2\text{SOCl}_2 + 3\text{S} = 2\text{S}_2\text{Cl}_2 + \text{SO}_2$. Sulphuryl chloride reacts similarly and at a lower temperature (100°—125° C.), sulphur monochloride and sulphur dioxide being formed: $\text{SO}_2\text{Cl}_2 + 2\text{S} = \text{S}_2\text{Cl}_2 + \text{SO}_2$. Thionyl chloride reacts with both red and yellow phosphorus at 150°—180° C. in accordance with the equation: $4\text{SOCl}_2 + 2\text{P} = 2\text{PCl}_3 + 2\text{SO}_2 + \text{S}_2\text{Cl}_2$. Sulphuryl chloride under similar conditions reacts according to: $3\text{SO}_2\text{Cl}_2 + 2\text{P} = 2\text{PCl}_3 + 3\text{SO}_2$. By prolonged heating in presence of excess of thionyl or sulphuryl chloride, the phosphorus trichloride is oxidised in accordance with the equations: $3\text{PCl}_3 + 4\text{SOCl}_2 = 3\text{PCl}_3 + 2\text{SO}_2 + \text{S}_2\text{Cl}_2$, $\text{PCl}_3 + \text{SO}_2\text{Cl}_2 = \text{PCl}_3 + \text{SO}_2$. Since the product of the reaction with thionyl chloride yields hydrogen sulphide on treatment with water, it seems that reaction takes place to some extent according to the equation: $3\text{PCl}_3 + \text{SOCl}_2 = \text{PCl}_3 + \text{POCl}_3 + \text{PSCl}_3$.—H. M. D.

Bromine; Method of extracting — from the mother liquors of marine salt works. G. Maganini, G. Bianchi, and G. A. Venturi. *Annali Chim. Appl.*, 1918, 9, 109—113.

A PLANT for the direct extraction of bromine, without preliminary concentration of the mother liquors, has been installed in the marine salt works at Corneto Tarquinia, where the mother liquors in the salt pans have a density of 15° B. (sp. gr. 1.116) and contain about 1 gm. of sodium bromide per litre. A measured current of air is pumped into the lower part of a stoneware tower communicating at the top with a horizontal tube, which is slightly inclined, and is surrounded by a jacket through

which passes cold mother liquor to cool the liberated bromine vapour. This tube is connected with an iron tube containing iron turnings, and the aqueous solution of iron bromide here formed is collected in a bottle at the outlet of the tube. A current of slightly acidified chlorine water is introduced into the tower from an overhead tank, and mixes with a current of heated mother liquor. The cold mother liquor receives a preliminary heating by passing through a system of double leaden pipes, the inner pipe of which conveys from the tower the hot liquid from which the bromine has been removed. The mother liquor is then conducted through a copper coil, where it is heated to over 80° C. before entering the tower. The liberated bromine is expelled by the current of air and forced into the tube of iron turnings above the tower. The solution of iron bromide is neutralised with sodium carbonate and evaporated to dryness, leaving a black granular mass from which boiling water will extract a white salt consisting mainly of sodium bromide with a variable amount of sodium chloride. The latter may be removed by boiling the salt with water in only sufficient quantity to dissolve the sodium bromide.—C. A. M.

PATENTS.

Sulphuric acid; Process of producing nitrous gases in lead chambers for the manufacture of —. R. Vetterlein, Schöningen. Ger. Pat. 303,557, Feb. 26, 1916.

THE hot gases passing from the roasting furnace to the Glover tower are made to act upon potassium nitrate or nitrite, or other nitrate or nitrite, or mixtures of such salts, preferably by spraying aqueous solutions of the salts into a tower through which the gases are passed. The resulting nitrous gases pass into the lead chamber, whilst the non-volatile constituents of the salts subside in the reaction chamber, but it is advisable to interpose a dust-catcher to prevent solid particles entering the Glover tower.—C. A. M.

Gases containing nitrogen oxides; Prevention of the premature formation of nitric acid in apparatus used for cooling —. J. Straub, Bochum. Ger. Pat. 304,002, July 18, 1915.

SULPHUR dioxide or trioxide or substances which yield those compounds on heating are introduced into the hot gases. The sulphuric acid which is thus formed and deposited on the cooling surfaces, unlike nitric acid, has but little action on metals such as wrought iron.—C. A. M.

Acetic acid; Preparation of concentrated from dilute —. Akt.-Ges. für Anilinfabrikation. Ger. Pat. 302,673, June 11, 1915.

DILUTE acetic acid is dehydrated by mixing it with kieserite, $\text{MgSO}_4 \cdot \text{H}_2\text{O}$, and a solvent such as chloro-

form, di- or tri-chloroethylene, or benzene, the anhydrous solution is removed from the solid mass, and distilled.—J. C. W.

Nitre cake in a disintegrated or ground form; Method for the obtaining of —. J. Grossmann, Manchester. Eng. Pat. 115,340, July 17, 1917. (Appl. No. 10,286 of 1917.)

At a certain critical temperature—about 50° C. for nitre cake containing 27% of free sulphuric acid, but varying with the content of free acid—nitre cake may be disintegrated by crushing or grinding more readily than under ordinary conditions. Accordingly, solidified or molten nitre cake is heated or cooled to the required degree and then disintegrated, the finer grinding being effected at or near atmospheric temperature.—W. E. F. P.

Pyrophosphoric acid and acid pyrophosphates; Manufacture of —. B. Levin, Hale, Chester. Eng. Pat. 115,693, May 16, 1917. (Appl. No. 7014 of 1917.)

To render pyrophosphoric acid and acid pyrophosphates stable and non-hygroscopic, suitable boron compounds (e.g., boric anhydride and pyrophosphoric acid) are incorporated with them during or after manufacture.—W. E. F. P.

Zinc sulphate solutions [containing arsenic and antimony]; Method of purifying —. R. B. Caples, Great Falls, and F. F. Fricke, Anaconda, Mont., Assignors to Anaconda Copper Mining Co. U.S. Pat. 1,263,852, Apr. 23, 1918. Date of appl., Sept. 4, 1917.

A solution of zinc sulphate, containing a dissolved copper salt in the proportion of at least one part by weight of copper for each part of arsenic or antimony trioxide to be eliminated, is treated at about 50° C. with metallic zinc, whereby arsenic and antimony are precipitated with the copper.

—W. E. F. P.

Bauxites, kaolins and other alumina-containing minerals; Method for the preliminary treatment of —. A. Prager, Leipzig. Ger. Pat. 299,072, June 8, 1915.

The method of introducing the cold bauxite, etc., into the hot or cold alkaline flux effects only partial decomposition in the case of certain kinds, notably Hungarian bauxites. More rapid and complete decomposition is effected by roasting the bauxite and introducing it while hot into the flux.

—C. A. M.

Salt and other substances; Process for preventing — from becoming damp and lumpy. P. Immerwahr, Berlin. Ger. Pat. 303,449, Nov. 22, 1916.

Amorphous silicic acid is added to salt for this purpose. It absorbs more moisture than other addition agents without the formation of lumps and is tasteless, without smell, and not injurious to health.—H. J. H.

Hydrogen peroxide; Process for obtaining stable compounds of —. E. Merck Chem. Fabrik, Darmstadt. Ger. Pat. 303,680, Sep. 23, 1911.

DILUTE solutions of commercial hydrogen peroxide are evaporated with neutral inorganic or organic substances (e.g., urea) to obtain stable compounds without the necessity of concentrating or purifying the hydrogen peroxide solution.—C. A. M.

Sulphurous acid; Process of preparing reduction products of —. Chem. Fabr. von Heyden A.-G. Ger. Pat. 304,107, June 6, 1914.

REDUCED iron or other form of iron containing little or no carbon is used in a finely divided condition for the preparation of hydrosulphites and sulphoxylates. The resulting solutions are free from iron, and better yields are obtained than when iron turnings, etc., containing carbon are used for the reduction.—C. A. M.

VIII.—GLASS; CERAMICS.

Refractoriness of firebricks, etc.; Effect of load on the —. J. W. Mellor and W. Emery. Report of Refractory Materials Research Committee of Inst. Gas Engineers. Gas J., 1918, 142, 478—481.

To determine the refractoriness of firebricks under load, a test-piece is cut from the brick and ground to a rectangular block $3\frac{1}{2}$ in. long and 2 in. cross section so as to present a surface of 4 sq. in. to the load. The block must be accurately measured and its top and bottom surfaces must be parallel. The test-piece is placed centrally and level on a solid refractory support, covered with a thin layer of powdered carborundum, in a modified Hirsch electric furnace. Small Seger cones, arranged in series of four, are fixed on the support around the test-piece. A cube of $2\frac{1}{2}$ in. side, of similar material to the support, is placed on top of the test-piece and, above this, a cylinder of magnesite and finally, a carbon rod mounted on an iron ring, the rod being attached to a lever-arm. As the temperature of the test-piece rises, its thermal expansion causes the lever-arm to rise, but later it begins to fall, the rate of deformation depending on the character of the test-piece. When the pre-arranged limit has been reached, the current is switched off, the weights, lever, etc., removed, and the cones examined. It was found impossible to have the inside and outside of the test-piece at the same temperature, but if the heating is arranged so that Seger cone 16 bends in four hours, the difference between the interior and exterior of the test-piece will be about 20° C. Tests of 20 fireclay bricks, which lost their shape without load at Seger cone 26—33, were made under a load of 50 lb. per sq. in. at Seger cones 14 to 26, most of the samples deforming steadily throughout the heating. Similar tests on six silica bricks which, without a load, lost their shape at Seger cone 29—34, were made under the same load at cones 3 to 31, four of the pieces collapsing suddenly, and the other two more steadily. The coarser-grained bricks gave the best results. The worst result (collapse at cone 3 under load) was obtained with a soft, red silica brick of fine, even

grain which has given good results in practice in settings of gas retorts. A commercial magnesia brick which, unloaded, had a refractoriness above cone 40, deformed slightly and collapsed at cone 18 when loaded with 50 lb. per sq. in. A German chromite brick behaved similarly at cone 13–14, and a zirconia brick with a normal refractoriness greater than cone 40 was deformed at cone 26–27 with a load of 25 lb. per sq. in., at cone 15–16 at 50 lb. per sq. in., and at cone 14–15 at 75 lb. per sq. in. The authors consider that a load of 50 lb. per sq. in. is too severe for fireclay bricks, and suggest one of 20–30 lb. The collapse of firebricks under load appears to be of two kinds: fusion collapse due to the gradual melting of the matrix, and mechanical collapse of an abrupt nature. The former predominates in fireclay, alumina, and zirconia bricks and the latter in silica, magnesia, and chromite bricks. A firebrick containing silica-grog may not show any difference from a brick made without grog when heated without a load but, when loaded, the former will show a higher result. The variations in refractoriness under working conditions are partly due to the different temperatures at various parts of the brick. One brick examined was found to have a steady temperature of 1000° C. at the hot end, 720° C. at a point $3\frac{1}{2}$ in. nearer the cool end, 570° C. at $4\frac{1}{2}$ in. from the hot end, and 350° C. at $6\frac{1}{2}$ in. from the hot end. If a brick is not inclined to spall, the softening of the hot face appears to do no harm. Some of the least resistant bricks when re-fired at cone 15–16 for two hours became much more resistant (cone 14 as compared with cone 9).—A. B. S.

Silica bricks: Influence of iron and lime as agglomerants in the manufacture of — M. Bied. *Comptes rend.*, 1918, 166, 776–778.

THE addition of 3, 4, and 5% of iron oxide respectively to a silica brick mixture did not induce the formation of a network of tridymite in the absence of lime, and no agglomerating action was observed. The inclusion of iron oxide in a silica brick mixture does not appreciably lower the fusibility of the brick, an addition of 3% Fe_2O_3 and 1% lime depressing the fusibility by only 5° C., which is within the error of determination. A ferruginous brick had expanded 1.8% after several days' exposure in an acid steel furnace and was sound, but the quartz grains had lost their individuality. —C. A. K.

Silica bricks: Composition of — after use in a Martin furnace. E. Rengade. *Comptes rend.*, 1918, 166, 779–781.

EXAMINATION of silica bricks from the crown of a Martin furnace shows that considerable changes have taken place, one of the most important of which is the conversion of quartz into cristobalite and tridymite (Le Chatelier, this J., 1917, 963, 964). Changes in chemical composition of different parts of the brick were studied after the brick had been subjected to the action of the furnace dust, and from the examination of a large number of such bricks the author differentiates four distinct zones. (A) The portion of the brick which has been immediately in contact with the flames, and is glazed, or at times has partially fused with the formation of stalactites. It is apparently homogeneous in structure, sometimes honeycombed, and grey in colour. (B) A black or dark grey section beneath A, usually distinctly separated from the latter, homogeneous, and of considerable hardness. (C) A transition zone often showing the larger grains of unconverted quartz in a black matrix, which latter recedes into a clear brown melt showing up the heterogeneous structure of the original brick.

(D) The remaining portion of the brick, which is apparently unchanged. Microscopic examination shows large transparent tridymite crystals in section B surrounded by an opaque black material, while in A these crystals are rounded by fusion but still distinct from the black matrix. As the cooler portion of the brick is approached tridymite occurs in diminishing quantity until the normal structure of the original brick is reached. Tabulated analyses of the different sections of silica bricks after use in acid and basic steel furnaces show considerable variations in the quantities of iron in the regions A and B and also in its state of oxidation, but generally B is richer in iron than A, and this can be explained by the black ferruginous constituent of the molten zone A moving into the region B between the crystals of tridymite under the influence of capillarity. A similar explanation would account for the transference of lime, as a fusible silicate, into the zone C. The presence of a considerable quantity of iron oxide does not appreciably affect the fusibility of silica bricks; even highly impregnated bricks stand well under furnace conditions.—C. A. K.

Silica; Action of iron oxide on — H. Le Chatelier and B. Bogitch. *Comptes rend.*, 1918, 166, 764–769.

THE necessary temperature for the production of steel is approximately 1650° C. and the fusibility of silica bricks rarely reaches 1750° C. Comparatively small increases in the temperature during steel making are therefore liable to cause fusion of the furnace lining. This difficulty is accentuated by the action of particles of iron which assist in the fusion of the crown of the furnace. The authors' results confirm those obtained by Rengade (see preceding abstract) and they use his classification of the differently heated regions A, B, and C, of silica bricks after use in a steel furnace, though preferring a division of zone C into two separate zones, as the yellow matrix differs from the black matrix in chemical composition. In the example of the different chemical composition of the zones given below, the figure for Fe_2O_3 includes about 0.5% Al_2O_3 .

	Brick prematurely fused, impregnated 9 cm. in depth.			Brick after long use, impregnated to a depth of 18 cm.		
	Sulphates	Fe_2O_3	CaO	Sulphates	Fe_2O_3	CaO
Original brick	10.5	1	2	8.5	1.5	1
Zone C ..	29.5	4.5	5	22	5.0	1.5
Zone B ..	29.5	4.5	5	26	6.5	2
Zone A ..	15	3.5	1.5	18	4.5	1.5

The grey zone directly in contact with the flame and exposed to the ferruginous particles contains less basic oxides than the zones further removed from the atmosphere of the furnace. The brown and yellow zones are much higher in lime, the increase being more marked by longer exposure of the brick in the furnace. Laboratory experiments indicated that the penetration of iron oxide is due to capillarity and by heating (to 1600° C.) a piece of the ferruginous brick on which was placed a similar piece of non-ferruginous brick, penetration of iron oxide was observed in the upper piece to a depth of 5 mm. The penetration of iron oxide into a silica brick heated in an oxidising atmosphere was not observed up to 1400° C., but reducing conditions caused considerable attack at 1200° C. The lessening of the proportion of basic oxide in the zone heated directly by the flame is due to the contraction of that portion of the brick, whereby the porosity is reduced and the ferruginous slag expelled into the cooler regions.

A briquette cut from the region B contracted 5% when subjected to a temperature of 1600° C. for one hour, whereas the original brick before contamination with iron oxide expanded 5% under the same conditions owing to the transformation of quartz into silica of lower density. This contraction becomes greater with increase in temperature even though the tridymite crystals expand under this treatment. In practice this contraction is readily observed, the face of the brick contracting (up to 10%) and falling away in a state of semi-fusion. If by faulty management of the furnace complete fusion occurs, the surface of the brick drips into the furnace with complete collapse of the crown, unless the conditions are altered. The aluminosilicates of calcium in the original brick are carried in advance of the ferruginous slag and concentration of lime occurs in the cooler regions. The region C containing 5% of lime would have a fusibility in the neighbourhood of 1600° C., with a fusibility of 1700° C. for the corresponding zone A. An increase in the temperature above 1700° C. would melt away the surface zone, and the region behind would in turn be quickly destroyed. A silica brick impregnated with iron oxide is regarded as being in a kind of unstable equilibrium, and its successful working necessitates a careful judgment of the temperature in the furnace.—C. A. K.

Constructional materials; Use of Brinell ball in testing [hardness of] — H. Le Chatelier and B. Bogitch. *Comptes rend.*, 1918, 166, 830–843.

The authors have adapted the Brinell ball test to the measurement of the hardness of bricks, by laying thereon a piece of thin lead foil, 30 mm. square and 0.05 mm. thick, previously blackened by treatment with hydrogen sulphide in a faintly acid solution, dried, and smeared with vaseline, most of which is wiped off again so that a matt surface is produced. The ball polishes the surface of the metal with which it comes in contact and this facilitates accurate measurement of the diameter of the depression. Tests with lead and copper showed that the foil does not interfere with the size of the depression produced. The ball used is 17.5 mm. diameter and is applied for 1 min. under a pressure of 500 kilos. The results are much more concordant than those obtained in determining the crushing strength of bricks. The test is useful in controlling the manufacture of bricks as it will show notable differences in the hardness of different parts of the same brick, due to irregularities in making or burning, or to an insufficient taper in the mould.—A. B. S.

PATENTS.

Graphite crucibles, bricks, and other refractory articles having graphite as a base; Baking — Soc. Nouvelle des Etablissements E. Muller, Ivry-Port, France. Eng. Pat. 109,247, June 14, 1917. (Appl. No. 8536 of 1917.) Under Int. Conv., Aug. 29, 1916.

CRUCIBLES or other refractory objects having graphite as a base are piled up in a kiln of existing type and are burned in direct contact with the flames and products of combustion instead of being placed in muffles or saggars. (Reference is directed in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pat. 3289 of 1871.)—A. B. S.

Furnaces or kilns for calcining limestone, fireclay, and other refractory materials. E. J. W. Richards, Glasgow. Eng. Pat. 115,316, June 7, 1917. (Appl. No. 8126 of 1917.)

A RECTANGULAR kiln is provided with hinged charging doors at the top and discharging doors at the

bottom along each side. Along the bottom of the kiln is a flue of approximately triangular cross section, with holes through which air is forced into the kiln so as to secure complete combustion of the fuel mixed with the material to be calcined. As the heating proceeds, the contents of the kiln descend and finally fall towards the discharging doors, through which they are removed from time to time.—A. B. S.

Kilns; Continuous or series — T. West, Durham. Eng. Pat. 115,696. (Appl. Nos. 7068, May 17, and 13,925, Sept. 27, 1917.)

A NUMBER of round or rectangular up- or down-draught kilns of the customary type are connected by damper-controlled flues so that all the kilns may be worked with either up- or down-draught or the kilns may be worked up- and down-draught alternately.—A. B. S.

Porous masses and objects; Process for the preparation of — N. V. Nederlandsche Gist- en Spiritusfabriek, Delft, and H. G. Moukhorst. Rijswijk, Holland. Ger. Pat. 304,854, Feb. 18, 1917.

THE gas-developing properties of yeasts or other micro-organisms in the presence of nutrient media are utilised as a means of obtaining a porous structure in objects, e.g., moulds and the like.

Kiln. U.S. Pat. 1,263,620. See I.

IX.—BUILDING MATERIALS.

Potash; Concentration of — from raw materials containing only a trace of this element by means of the electrical precipitation of flue dust and fume from cement kilns. B. F. Erdahl. J. Ind. Eng. Chem., 1918, 10, 356–359.

IN a cement plant using limestone and blast-furnace slag, with powdered coal as fuel, a series of analyses of the limestone, slag, coal ash, clinker, and precipitated dust were made to determine the potash content. It was found that the potash content of the limestone and clinker was constant, that of the slag varied from 0.28 to 0.69%, that of the coal ash varied from 1.20 to 1.52% and the potash in the precipitated dust increased with the number of electric precipitators used. The charge becomes richer in potash as the dust is continuously returned to it. About 30% of the total potash remains in the clinker and 70% is volatilised. About 30% of the volatilised potash is deposited in the rear end of the kilns, the housings, and gas coolers, and less than 2% is lost through the stacks. The analyses of the returning dust from the precipitators gave a decreasing potash content for successive cycles. The deposited dust in the rear end of the kilns increased in amount with each cycle, indicating that choking would eventually occur. The potash content of the dust escaping through the stacks decreased for successive cycles.—W. F. F.

Influence of iron and lime as agglomerants in the manufacture of silica bricks. Bied. See VIII.

Shaft-furnaces for burning cement, lime and similar substances. A. and W. W. Steiger, Zürich, Switzerland. Eng. Pat. 109,266, Aug. 28, 1917. (Appl. No. 12,370 of 1917.) Under Int. Conv., Aug. 30, 1916.

A ROTARY hearth, fitted with a stepped helical surface and two groups of cutting edges, is placed in the lower part of a shaft furnace to form an automatic discharging device.—A. B. S.

Kilns for burning cement, lime, or the like. A. Steiger, Zürich, Switzerland. Eng. Pat. 111,854, Nov. 27, 1917. (Appl. No. 17,543 of 1917.) Under Int. Conv., Dec. 4, 1916.

COMPRESSED air is passed through a series of ducts in the walls of a shaft kiln and thence through numerous adjustable openings into the interior of the kiln. The gaseous products of combustion are drawn off by an exhaustor connected to openings near the top of the kiln. The air supplied through the conduits close to the sole of the kiln is at a higher pressure than that supplied through the conduits nearer the burning zone.—A. B. S.

Alkali-containing minerals; Process for decomposing — [for production of cement with volatilisation of the alkali]. F. Krupp A.-G. Grusonwerk, Magdeburg-Buckau. Ger. Pat. 304,080, Apr. 9, 1914.

THE mineral is heated with calcium carbonate and the calcium salt of another acid, and in certain cases with a corrective agent—*e.g.*, silica—so as to obtain simultaneously the total alkali and a cement. The calcium salt of the other acid must be added in the proportion necessary for combining with the alkali, and if the mineral does not contain sufficient iron to form about a quarter of the weight of the total sesquioxides present, a corresponding quantity of ferric oxide must be introduced. Under these conditions the decomposition is practically quantitative at a lower temperature than is required for the formation of clinker. In the case of a mixture of felspar, chalk, calcium sulphate, and ferric oxide, the reaction takes place in two stages—

(1) Heating zone below 1300° C.
 $6\text{SiO}_2 + 21\text{CaO} + \text{Al}_2\text{O}_3 + \text{Fe}_2\text{O}_3 + \text{K}_2\text{SO}_4 + 20\text{CO}_2.$

(2) Sintering zone above 1300° C.
 $6(\text{SiO}_2 \cdot 2\frac{1}{2}\text{CaO}) + \text{Al}_2\text{O}_3 \cdot 3\text{CaO} + \text{Fe}_2\text{O}_3 \cdot 3\text{CaO}.$

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Hæmatite; Concentration of silicious red — J. T. Singewald, jun. U.S. Bureau of Mines, Bull. 110. 84 pages.

THE Birmingham district of Alabama possesses large beds of ferruginous sandstone, consisting of red hæmatite with varying percentages of silica and other impurities. Where the bed has not been leached by surface water, the ore is hard and ranges in composition from 32 to 45% Fe, 5 to 20% CaO, 2 to 25% SiO₂, 2 to 5% Al₂O₃, 1 to 3% MgO, 0.25 to 1.5% P, and up to 0.5% S. The value of the ore depends to a large extent on the approximation to a self-fluxing character, that is, on the relative quantities of SiO₂ and CaO. In the concentration

tests the ore was crushed to pass a 20-mesh screen, and a screen analysis was then made (by the Tyler standard) ranging from particles of 0.833 mm. diam. to particles of less than 0.074 mm., the latter being regarded as slime. The heavier particles high in iron were separated by the use of "Thoulet solution" of sp. gr. 3.0, and by the combined processes each sample yielded seven sizes of concentrates and of tailings, besides the slime. 39 samples were examined in this way and the detailed results are given. The hard ores cannot be profitably worked if the content of SiO₂ exceeds that of CaO by more than 8%, and by concentration the quality of the concentrates can be made at least equal to that of ores which at present are successfully worked. In the case of an extremely poor sample from the Ruffner mine, with silica in excess of the iron, averaging 28.8% Fe and 30.9% SiO₂, the concentrates averaged 40.5% Fe and 17.1% SiO₂ for example. Of the total iron in the crude ore, in all the samples tested, that in the concentrates averaged 80.6% and that in the slimes 13.1%, making a recovery of 93.7%. The average composition of the concentrates was 46.4% Fe and 13.4% SiO₂, and of the slimes 44.7% Fe and 13.5% SiO₂. The method of concentration employed would not be feasible in commercial working but as a definite concentration of iron is indicated, the devising of a separation on commercial lines may be possible.

—C. A. K.

Carbon; Rapid determination of total — in steel and cast iron. E. Sernagiotto. Annali Chim. Appl., 1918, 9, 113–114.

FROM 1 to 3 grms. of the finely-divided metal is treated with 50 c.c. of a 30% aqueous solution of the double chloride of copper and potassium (CuCl₂ + 2KCl) acidified with a few drops of hydrochloric acid, the reagent being added in one portion with constant shaking. As soon as the iron has dissolved, the beaker is heated and the solution filtered with the aid of suction through an asbestos filter contained in a perforated copper thimble resembling a Gooch crucible. The filter is washed with a little of the reagent acidified with hydrochloric acid and then with water, and the thimble dried at 100° C. The carbon is then determined by combustion in a current of oxygen.—C. A. M.

Iron alloys; Influence of the chemical composition and heat treatment of — on their magnetic properties, specific resistance, and density. Gümlich. Chem.-Zeit., 1918, 42, 200–201.

THE density and specific resistance of the alloys investigated containing iron with carbon, silicon, aluminium, and manganese, generally vary in a regular manner with alteration in the percentage of the added elements, so that it is possible, with good agreement with the results of direct measurement, to calculate from the figures for the alloys the corresponding values for pure iron. Irregularities in the course of the curve showing the relation between these physical properties and the composition are encountered only with alloys containing a high percentage of carbon or manganese, the latter at a proportion of 8–10% and the former at the point at which cementite may be formed in a matrix of pearlite or martensite. Analogous irregularities are observed in the curves for coercive force and saturation value, the latter having its maximum for pure iron. The view that the addition of silicon or aluminium improves the magnetic properties of iron is therefore erroneous, this belief having arisen from the effect of these elements in reducing the oxygen content and in preventing the presence of the deleterious dissolved carbon. Aluminium and silicon also possess the technically important characteristic of increasing

the specific electrical resistance and thereby reducing the tendency to eddy currents. Manganese, on the other hand, checks the separation of dissolved carbon and is therefore undesirable. All four ingredients cause a reduction in the true remanence of iron. Electrolytic iron after being heated and then cooled slowly, exhibits high remanence and permeability whereas after quenching the remanence and permeability are slight; on repeated heat treatment the hysteresis loops gradually become more oblique and narrower; rolled sheet iron, however, does not exhibit this behaviour. Manganese and quenched carbon alloys possess several analogies; both show a simultaneous increase in the coercive force and decrease in the remanence when the percentage of the characteristic elements is raised; in order to obtain high coercive force and high remanence simultaneously it is necessary to introduce tungsten, chromium, or molybdenum. Unlike the higher manganese alloys, the carbon alloys on quenching from above 700° C. become magnetically harder than when cooled slowly.—D. F. T.

Iron-silicon alloys unattacked by acids. C. Matignon. Comptes rend., 1918, 166, S15—S18.

VARIOUS iron-silicon alloys produced in different countries in 1913 were compared with one another and with samples of ferroboration and Borchers' metal. The specimens examined had the following compositions:—

	French	Italian		American		
	Métallure	Ellanite I	Ellanite II	Ironac	Duriron	Ferroboration
Si ..	16.92	15.07	15.13	13.16	15.51	4.9
Fe ..	81.05	82.40	80.87	83.99	82.23	69.8
Mn ..	0.88	0.62	0.53	0.77	0.66	3.3
Ni ..	—	—	2.23	—	—	—
Al ..	0.25	—	—	—	—	3.1
C ..	0.592	—	0.82	1.08	0.83	—
P ..	0.173	—	0.06	0.78	0.57	—
S ..	0.01	—	0.03	0.05	0.01	—
Ca and Mg	—	—	—	—	—	—
B ..	—	—	—	—	—	15.4
Sp. Gr. ..	6.71	6.87	7.11	6.71	6.94	—

Borchers' metal was prepared from the following mixture: Ni 64.6; Cr 32.3; Ag 0.5, Mo 1.8 parts. As regards resistance towards nitric acid the ferroboration did not resist the action of the acid either weak or strong. Contrary to the general rule Borchers' alloy was more resistant to the weak acid (20° B., sp. gr. 1.16) than to the strong acid (36° B., sp. gr. 1.33), but it did not show any advantage over the iron-silicon alloys, which are cheaper. The introduction of 20% of nickel improved the resistance of the alloy to acid as between Ellanite I and II. Métallure gave the best results, it being a homogeneous alloy with regular texture and apparently more carefully refined. None of the alloys resisted the action of hydrochloric acid. (See also Tungay, this J., 1918, 87 T.)—W. G.

Copper melts containing gases; Effect of tin on —. W. Stahl. Metall u. Erz, 1918, 15, 67.

Tin separates from molten copper in an oxidising atmosphere as tin dioxide, or as a stannate if other metals are present. After the commencement of the reaction between cuprous oxide and sulphide, the tin reacts with the former according to equation: $2\text{Cu}_2\text{O} + \text{Sn} = 4\text{Cu} + \text{SnO}_2$. When sulphur dioxide is present in solution the following reaction occurs: $\text{SO}_2 + \text{Sn} + 2\text{Cu} = \text{SnO}_2 + \text{Cu}_2\text{S}$. The addition of 1.3% of tin raises the specific gravity of refined copper from 8.625 to 8.9135. Small quantities of tin added to copper act as a deoxidiser similarly to phosphor-copper.—F. C. Th.

Copper; Influence of the temperature of rolling, the amount of work, and annealing on some properties of —. P. Oberhoffer. Metall u. Erz, 1918, 15, 47—56.

The material used was intended for locomotive fire-boxes and had the following composition: 99.46% Cu, 0.28% Sn, 0.231% As, 0.11% O. Specimens quenched in water after rolling possessed similar properties to those cooled in air. In the case of samples hot rolled at temperatures between 300° and 800° C., the increase of breadth was relatively large while the elongation was small, but above and below these temperatures the broadening decreased and the elongation increased.

Influence of heating to the temperature of rolling. In the case of the cast metal, the tensile strength and hardness after the cooling down altered very little as the temperature to which the samples were heated was raised. The elongation and the reduction of area remained practically constant to 800° C. but then decreased. The structure of the cast metal showed dendritic crystals which appeared bright under oblique illumination, and were low in arsenic and oxygen. The arsenic and the cuprous oxide eutectic were concentrated between the branches of the dendrites rendering the crystals much finer grained. The crystal size did not much affect the strength of the cast metal, but influenced the external appearance of the broken tensile test-pieces. Annealing did not change the crystal size of the cast copper nor did it produce equilibrium in the arsenic content by diffusion. In the case of copper which had been previously reduced 85% in thickness by rolling, the strength and hardness were hardly influenced at all by subsequent heating to the rolling temperature, the tensile strength showing a reduction of only 2 kilos. per sq. mm. after heating to 1000° C. The elongation and reduction of area fell as the temperature was raised to 200° C., then increased, and remained constant from 300° C. to 500° C. A rapid rise occurred between 500° and 600° C., when the values remained constant to 900° C. after which a fall again set in. The structure of the metal showed no correlation with these changes, being more in agreement with the strength and hardness curves. The crystal size was almost constant till an increase occurred from 600° C. to 1000° C. In spite of the large amount of work done upon the specimens, traces of the original dendritic structure were clearly visible, and the parallelism of the zones rich in cuprous oxide and arsenic gave a banded structure analogous to that of hot-rolled structural steels. The increase of strength (7 kilos. per sq. mm.) and hardness (10) compared with the cast and unworked metal, is due not only to the change in the crystal size but also to that in the arrangement of the oxide- and arsenic-rich areas.

Influence of the temperature of rolling. In the case of cast copper, the hardness and tenacity fell slowly as the temperature was increased to 500° C. and then more quickly to 700° C., remaining almost constant to 900° C., after which a further fall occurred. The elongation and reduction of area increased rapidly from 600° C. to 700° C. and no decrease from 900° C. to 1000° C. was observed. Between 600° C. and 900° C. the resistance to impact increased rapidly. The structure of the pieces rolled up to 600° C. showed distinct elongation of the crystals, but between 600° C. and 700° C. a sudden change in structure occurred which was clearly expressed in the elongation curve. Above 700° C. the crystals were no longer elongated. Above 900° C. a noteworthy increase in the coarseness of the crystallisation occurred. In the case of previously worked material the curves were similar to the foregoing, but the impact value rose more sharply and the increase occurred not between 600° C. and 700° C. but between 400° C. and 500° C.

The elongation curve showed a rise between 400° C. and 500° C., but only attained its maximum at 700° C. Further, elongation of the crystals was observed only up to 400° C., thus clearly showing that the smaller crystals of the worked metal need a distinctly lower temperature to produce recrystallisation than do the coarser ones of the cast material. With the worked copper rapid crystal growth did not occur till 900° C., but at 1000° C. the crystallisation in the cast and worked samples was almost identical. The elongation, however, of the worked metal was 20% higher than that of the cast. In this material the tensile strength is not determined solely by the crystal size, the amount of work exerting a considerable influence.

Influence of the rolling:—The curves of both the cast and previously worked materials were similar, but the hardness and strength in the latter case were consistently higher than in the former. Below 650° C. the rolling operations correspond to "cold-rolling" and above that temperature to "hot-rolling." Annealing at 650° C. after rolling at temperatures from 600° C. to 1000° C. produced no improvement. For a reduction of 85% 500° C. is the lowest temperature that can be used, and 600° C. is better; 800° C. should not be exceeded as an upper limit. At 900° C. the structure, tensile and impact properties deteriorate and a sudden change in the relations of broadening to elongation during rolling occurs. The influence of the extent of the rolling upon the mechanical properties is summarised in the following table:—

Reduction %	Maximum stress, kilos per sq. mm.	Elongation, % on 100 mm.	Reduction of area, %	Hardness
0	17.0	18.0	18.0	46
50	21.5	27.0	27.0	63
92.5	23.0	48.0	49.0	60

—F. C. Th.

Oxygen in copper; Estimation of — P. Oberhoffer. Metall u. Erz, 1918, 15, 33—35.

AFTER briefly reviewing other methods suggested for the determination of oxygen in copper, a modification of Hampe's method (Z. anal. Chem., 1874, 13, 188) is described, whereby the time required is reduced to $\frac{3}{4}$ hour and the necessary apparatus is simplified. The apparatus consists of an electrolytic hydrogen generator with purifiers, a mercury air-pump, an electric oven with silica tube in which the sample is heated, and a phosphorus pentoxide guard-tube. A temperature of 800° C. is used, and 5 minutes is sufficient for the complete reduction of the cuprous oxide present, the complete estimation taking 45 minutes.—F. C. Th.

Zinc blende and some other minerals; Magnetic properties of — F. Stutzer, W. Gross, and K. Bornemann. Metall u. Erz, 1918, 15, 1—9.

MANY zinc blendes are sufficiently magnetic to be attracted by strong magnetic fields. The authors have devised a method by which the susceptibility of such materials can be measured and have carried out determinations on 19 samples of zinc blende and on several other minerals. Minerals having susceptibilities less than 20×10^{-6} are practically unmagnetisable, and to this class belongs pure zinc blende in addition to gangue materials such as quartz, calcite, fluor spar, and barytes. The presence of iron in zinc blende increases the susceptibility, though not in any definite manner; with 14.7% Fe the susceptibility is over 500×10^{-6} . Manganese, nickel, and cobalt also increase the susceptibility as in the case of copper ores and salts. Some measurements are also given for ferro-magnetic minerals such as magnetite, but these are less reliable.—F. C. Th.

Zinc; Electrothermal production of — H. Nathusius. Metall u. Erz, 1918, 15, 87—93, 108—111.

ATTEMPTS made hitherto to apply electric heating to the extraction of zinc from its ores have, in the opinion of the author, been unsuccessful. The principal cause lies in the fact that electric furnaces hitherto constructed have not solved the problem of the condensation of the zinc vapour to liquid metal. In most cases a high percentage of zinc dust is formed which must be remelted, rendering the process uneconomical. No resistance furnace has previously been constructed which will attain the high temperature, 1200° C. to 1300° C., which is required, and the arc type of furnace must be entirely excluded since, apart from other disadvantages, at the temperature of the electric arc the temperature and pressure relations of the reduction are completely changed and cannot be allowed for.

The author has designed a furnace in which the following points have been considered:—The furnace must be gas-tight during reduction, distillation, and condensation; the gases formed must be at once removed; the heating must be gradual and uniform throughout the charge; the temperature reached should not exceed 1200° C., and the process should be continuous.

The furnace is described in detail and illustrated. It consists essentially of a shaft, preferably vertical, in which the reduction by carbon occurs. Zinc vapour distils off through side flues into a condensing chamber maintained at 500° C., from which the molten zinc is tapped off. The heating is produced by the current introduced through cast steel electrodes built into the walls. An alternating current at from 5 to 15 volts is used. The whole furnace is cased in an iron sheath and is gas-tight. The zinc vapour and carbon monoxide are drawn into the condenser by an exhaust pump. The charge is preheated (by the hot products of the reaction) to about 900° C. in a conical continuation of the reducing chamber. The heating is claimed to be uniform and very efficient. In a test a charge of 1000 kilos. of ore, containing 64% ZnO, and 267 kilos. of coal was treated with an expenditure of 920 kilowatt-hours. The cost is claimed to be little more than that of the gas-heated muffle furnace, while advantages are obtained in the directions of purity of metal, uniformity of heating, economy of space and labour, the possibility of working poor ores containing lead and copper, economy in carbon and refractory materials, smaller loss of metal, and simplification of transport.

—F. C. Th.

Tin; Recovery and losses of — at Giew Mill. Cornish Sub-Committee, Tin and Tungsten Research Committee. Bull. 164, Inst. Min. and Met., May, 1918. [Advance copy.] 11 pages.

THE mill was run for 71 days under the supervision of the Sub-Committee, in order that exact data on the losses in milling might be obtained. The tin recovered in the concentrate was 67.5%, while the direct determination of the loss in the effluent gave 35.5%. The original ore contained 1.4% SnO₂.

—W. R. S.

[Tin.] *Giew Mill test. Elutriation of the crushed products.* S. J. Truscott. Inst. Min. and Met., Bull. 164, May, 1918. [Advance copy.] 6 pages. (See preceding abstract.)

THE battery feed, the tubemill feed and tailing, and the final tailing and concentrate were elutriated, and the products assayed. The bulk of the tin was found in the coarser sizes of the feed (down to -200 mesh), proving that cassiterite does not suffer undue comminution in crushing and re-grinding. More than two-thirds of the concentrate was coarser than 300-, and nearly one-half coarser than 200-mesh.

—W. R. S.

White metals; Analysis of —. P. Drawe. Z. angew. Chem., 1918, 31, 88.

THE approximate composition of white metals may be ascertained as follows. One grm. of the sample is decomposed with nitric acid, the solution is diluted and boiled, and the hydrated tin and antimony oxides are collected on a filter. The mixed oxides are then heated at 80° C. for 1 hour with hydrochloric acid and iron dust, cooled, the precipitated antimony collected on a filter, and the stannous chloride in the filtrate filtrated with ferric chloride solution. The antimony precipitate is washed with dilute hydrochloric acid until free from iron, ignited, and weighed. The filtrate from the tin and antimony oxides is treated in the usual way with sulphuric acid to separate the lead, copper is precipitated as sulphide in the filtrate from the lead sulphate, iron is precipitated with sodium hydroxide after oxidation with bromine, and zinc as carbonate.—W. P. S.

Ore flotation; Molecular physics of —. W. H. Coghill and C. O. Anderson. J. Phys. Chem., 1918, 22, 237–255.

THE principles involved in the flotation of solids in liquids are discussed. Methods of constructing liquid profiles are considered, and a formula is derived by means of which angles of contact may be calculated from cathetometric measurements of the rise or fall of liquids in contact with vertical plates. The connection between flotation and the angle of contact is indicated by curves. Measurements of the water profile in the case of floating steel and aluminium wires and of floating galena are recorded.—H. M. D.

Composition of silica bricks after use in a Martin furnace. Rengade. See VIII.

Action of iron oxide on silica. Le Chatelier and Bogitch. See VIII.

Estimation of copper as copper oxide after precipitation as thiocyanate. Fenner and Forschmann. See XXIII.

Use of metallic silver as a reducing agent in the volumetric estimation of iron. Edgar and Kemp. See XXIII.

PATENTS.

Iron; Protecting surfaces composed of or containing — from chemical action. D. Reichlinstein, Zürich, Switzerland. Eng. Pat. 103,814, Nov. 14, 1916.

ESTERS of arsenious or antimonious acid, dissolved in oil, or in organic solvents, by means of which they are incorporated with oil or fat, are applied to the surface to be protected, or the esters may be added directly to the water which comes into contact with the metal surface, e.g., in a boiler.

—T. H. B.

Iron or other magnetic metals; Process for obtaining coatings of — by the spraying process. A. Wolf, Hamburg. Ger. Pat. 301,971, June 6, 1917.

OBJECTS to be coated with iron or the like are magnetised during the process, whereby the coating adheres more firmly.—F. C. Th.

Phosphatic slags; Method of producing high-grade — in the manufacture of iron or steel from high-sulphur pig iron. B. Queling, Saarbrücken. Ger. Pat. 302,283, Nov. 11, 1916. Additions to Ger. Pat. 301,839.

CAST iron from a mixer is, while being transferred to open-hearth furnaces, opposed by a blast of compressed air. This prevents the slag, high in silica and sulphur, and the light iron-sulphur alloy which is supposed to float on the surface of the iron in the mixer, from entering the second furnace, where a new, undiluted and highly phosphoric slag can be produced.—F. C. Th.

Iron articles; Process for introducing nitrogen into —. J. Pintsch A.-G., Berlin. Ger. Pat. 302,306, Sept. 24, 1916.

THE iron articles are carried on an endless chain into a chamber in which collects the hydrogen produced by the decomposition by heat of ammonia. The hot gas preheats the objects which are carried on into a hot zone of decomposing ammonia in which surface nitrogenation occurs. From here the chain carries the charge into colder nitrogen after which the articles are quenched in a water bath which acts as a gas seal.—F. C. Th.

Charcoal iron; Method for preparing a substitute for —. Rombacher Hüttenwerke, J. I. Bromm, and W. Schemmann, Rombach. Ger. Pat. 302,358, Oct. 5, 1915.

ORDINARY cast iron is refined in a basic-lined Bessemer converter or in a basic open-hearth furnace until the impurities are removed (e.g., carbon to about 0.1%). The liquid ingot iron is then brought into intimate contact with 6–7% of its weight of charcoal, when, if the temperature is kept sufficiently low and the duration of the process is not excessive, a satisfactory substitute for charcoal iron may be produced.—F. C. Th.

Steel; Method for the oxidation of the phosphorus before the carbon in the manufacture of — by the basic Bessemer process. W. Gontermann, Siegen. Ger. Pat. 302,768, Apr. 5, 1917.

By using a high-pressure blast in the basic lined Bessemer converter, the oxidation of the phosphorus is accelerated and that of the carbon delayed and with a certain pressure the order of oxidation of the two elements can be reversed. When the phosphorus has been removed the blast pressure can be lowered, when at the prevailing high temperature the carbon is rapidly oxidised. It is possible to decarburise to any desired extent.

—F. C. Th.

Ferro-chrome; Process for manufacture of very low-carbon —. Stahlwerke R. Lindenberg, Remscheid-Hasten. Ger. Pat. 302,675, Feb. 5, 1916.

A HIGH-PERCENTAGE ferro-silicon is melted in a reducing atmosphere in an electric furnace and covered with a mixture of commercially pure chromium oxide and lime. Ferro-chrome containing up to 80% Cr can easily be produced starting from a correspondingly high-percentage ferro-silicon, and a 98% ferro-chrome has been prepared.

—F. C. Th.

Ferro-alloys; Method of producing low-carbon —. Stahlwerke R. Lindenberg, Remscheid-Hasten. Ger. Pat. 302,862, Feb. 5, 1916. Addition to Ger. Pat. 302,675. (See preceding abstract.)

INSTEAD of chromium oxide technically pure oxides of tungsten, molybdenum, vanadium, titanium,

cobalt, and boron may be added (together with lime) to the molten ferro-silicon to produce the corresponding ferro-alloys.—F. C. Th.

Galvanising articles of iron; Process for hot — after heating them in liquid lead. F. Köster, Hamm. Ger. Pat. 302,268, July 30, 1916.

Iron wires are heated to 750° C. in a lead bath and transferred quickly to a bath of molten zinc.

—F. C. Th.

Alloys; Manufacture of metal —. Stabilimenti "Biak" A. Pouchain, Assignees of P. Peynetti, Turin, Italy. Eng. Pat. 111,288, Nov. 5, 1917. (Appl. No. 16,129 of 1917.) Under Int. Conv., Oct. 23, 1916.

Two or more of the constituents of an alloy are melted in a chamber wherein one or more of the other constituents exist in the state of vapour.

—T. H. B.

Copper or other metals or compounds thereof; Extraction of — from ores. J. S. Ross and G. L. Crump, London. Eng. Pat. 115,088, Apr. 25, 1917. (Appl. No. 5835 of 1917.)

Ore containing small quantities of the metal as carbonate (e.g., copper carbonate) is subjected, in lump form as mined, to the leaching action of a 5 to 10% solution of sulphuric acid, or of a substance containing sulphuric acid, e.g., nitre cake. The metal is then obtained from the solution by electrolysis or other known method.—C. A. K.

Copper; Process for extracting — from its ores. E. Anderson, Assignor to International Precipitation Co., Los Angeles, Cal. U.S. Pat. 1,263,727, Apr. 23, 1918. Date of appl., Aug. 15, 1916.

Copper ore containing a carbonate is leached with a solution containing a ferrous salt, cupric chloride, and a chloride capable of retaining cuprous chloride in solution; copper is precipitated from a portion of the solution thus obtained and the solution then subjected to oxidising action sufficient to convert the cuprous salt to cupric, whilst leaving a substantial portion of the iron salt in the ferrous state.—T. H. B.

Copper alloys; Method for the improvement of —. P. Goldstein, Hannover. Ger. Pat. 302,962, Dec. 24, 1912. Addition to Ger. Pat. 208,657 (this J., 1914, 201).

Alloys of copper and zinc, tin, or aluminium containing small proportions of high melting-point metals such as titanium, vanadium, uranium, zirconium, tungsten, chromium, or molybdenum, are prepared as follows:—A briquette of very finely divided uranium or other oxide is reduced with molten sodium in a crucible and brass turnings are added, the melt stirred well, and cast at the highest possible temperature. The alloys are very ductile and have a high resistance to chemical action.

—F. C. Th.

Furnaces; Electric — for melting or refining non-ferrous alloys. V. C. Faulkner, Sheffield. Eng. Pat. 115,248, Feb. 2, 1917. (Appl. No. 1674 of 1917.)

The crucible of the furnace is surrounded by a mass of granular carbon, with adjustable electrodes projecting through the sides of the outer walls of the furnace, and a third electrode is fixed under the bottom of the crucible. An upstanding central hollow boss may be arranged on the floor of the furnace chamber for supporting a crucible smaller than the containing chamber, the cavity on the underside of the boss being filled with a heating medium, such as coke or broken electrodes.—B. N.

Furnace; Combined tilting and reversible open-hearth melting — and converter. A. Rollason, Nottingham. Eng. Pat. 115,323, June 16, 1917. (Appl. No. 8653 of 1917.)

The furnace has a cylindrical body which rests upon, and may be rotated in, a cradle provided with trunnions, the latter being mounted in bearings in hangers or pedestals. The body is lined with acid and basic material on opposite sides; has tuyères and ports for the admission of gas or oil and air (or, alternatively, electrodes); and is fitted with a circumferential toothed metal rack operated by spur and worm gear. One of the trunnions on the cradle is also provided with spur and worm gear for the purpose of tilting the furnace.—W. E. F. P.

Crucible furnaces. J. Connolly, Birmingham. Eng. Pat. 115,543, July 19, 1917 (Appl. No. 10,396 of 1917.)

The furnace may comprise a single chamber with double walls, the air traversing the heated annular channel, and passing through slits in the inner wall into the combustion chamber; or, primary and secondary chambers may be connected by a flue, the secondary chamber being heated by the flue gases from the primary chamber, and serving as a pre-heating furnace. The space between the two chambers can be used as a regenerator, the air for the combustion of the fuel being conveyed through pipes which are contained in this space and which are heated by the waste gases from the secondary furnace. Alternatively, a combination of the two forms may be employed.—C. A. K.

Zinc; Extraction of —. The New Delaville Spelter Co., Ltd., Birmingham, and E. H. Shortman, jun., Bloxwich. Eng. Pat. 115,409, July 19, 1917. (Appl. No. 10,385 of 1917.)

A zinc retort is connected with a condenser of large capacity by a passage provided with a lead-intercepting and filtering device. The condenser is provided with an opening through which gases escape during the first stage of the process, but is closed by a plug while the zinc vapour is passing over.

—T. H. B.

Zinc ores, calcined pyrites, and other metallurgical products; Method of dead-roasting low-grade sulphur-bearing, specially —. W. Buddéus, Berlin. Ger. Pat. 302,880, Oct. 5, 1916.

The ore is roasted in a vertical shaft furnace with a blast chamber below the grate. The process is continuous, new material being introduced as the calcined ore is removed.—F. C. Th.

Ores; Treatment of —. J. B. Vogelsang, St. Louis, U.S.A. Eng. Pat. 115,697, Mar. 17, 1917. (Appl. No. 7078 of 1917.)

A mixture of crushed ore, water, and oil is forced into a chamber by other than mechanical means, e.g., by a steam jet, the outlet of the chamber being somewhat restricted, so as to cause thorough emulsification. The outlet of this chamber is connected with a separating tank. An inner chamber having perforated walls may be provided to assist the emulsification. The fine particles of metal in the pulp are enmeshed and retained in suspension in the froth, whilst the heavier waste material settles out.—C. A. K.

Acid resisting metal, and articles made thereof. A. E. Gillespie, London, and E. E. Sheather, Teddington. Eng. Pat. 115,750, Aug. 1, 1917. (Appl. No. 11,102 of 1917.)

A bar or plate of chromium alloy steel of the kind known as "stainless" or "rustless" steel (a low-

carbon steel containing 10 to 15% Cr) is welded to a bar or plate of ordinary mild steel, by hammering or rolling under the action of heat. The composite plate is then heated and rolled to any required thickness for the manufacture of culinary utensils or cans for the storage of foodstuffs, the resulting sheet having one incombustible surface. The mild steel may be coated on both sides, and is then particularly suitable for the manufacture of dental plates.—C. A. K.

Float metal; Process and apparatus for the recovery of — from water containing the same. J. H. Reed, Philadelphia, Pa. U.S. Pat. 1,262,984, Apr. 16, 1918. Date of appl., July 25, 1917.

Water containing float metal is caused to flow under a layer of oil, and by means of baffle-plates the float metal is caused to impinge on the under surface of the oil, thereby being entrapped.

—C. A. K.

Metals from ores; Process of recovering —. H. E. Wood, Denver, Colo. U.S. Pat. 1,263,503, Apr. 23, 1918. Date of appl., May 11, 1916.

The concentrate obtained by subjecting dry-crushed, non-oxidised ore to a film tension flotation process is heated to oxidise undesirable constituents, then mixed with water and oil, and again treated by flotation to recover the oiled, metalliferous particles.—W. E. F. P.

Tungsten-reducing [electric tube] furnace. C. A. Pfau, St. Louis, Mo., Assignor to Pfau-St. Louis Co., Inc., North Chicago, Ill. U.S. Pat. 1,263,598, Apr. 23, 1918. Date of appl., Oct. 15, 1915.

The tungsten trioxide to be reduced is contained in nickel trays arranged one above the other, with intervening spaces for the passage of the hydrogen used as reducing agent. This portion of the furnace tube is surrounded by a heating element by means of which a constant temperature is maintained throughout the length of the reducing zone of the furnace, whilst at the inlet end the tube is provided with another electric heating element directly in contact with the hydrogen, by means of which the latter is heated before coming in contact with the tungsten trioxide.—T. H. B.

Tungsten or molybdenum; Process of coating or joining articles of —. F. A. Fahrenwald, Cleveland, Ohio, dedicated to the Government and people of the United States. U.S. Pat. 1,263,656, April 23, 1918. Date of appl., May 31, 1916. (Dedicated to the public.)

Articles of tungsten or molybdenum or their alloys are coated by heating them in contact with a dry flux containing a finely-divided precious metal, mixed with an alkali salt, to a temperature at least as high as the melting point of the precious metal. The coated articles may be soldered by means of a metal or alloy which will alloy with the precious metal.—T. H. B.

Composition [alloy] for resisting heat. M. R. Wolfard, Cambridge, Mass., Assignor to L. A. Ames, Spencer, and E. B. Kent, Newton, Mass. U.S. Pat. 1,263,831, Apr. 23, 1918. Date of appl., Aug. 8, 1916.

For withstanding the action of an oxidising flame at high temperature, an alloy composed of iron, 2, and nickel, 1 to 4 parts, and containing relatively little carbon, is employed in the cast condition.

—W. E. F. P.

Metal-bearing material for sintering; Method of preparing finely-divided —. F. W. Yost, Assignor to American Ore Reclamation Co., New York. U.S. Pat. 1,263,832, Apr. 23, 1918. Date of appl., Feb. 27, 1915.

Finely-divided, damp, metalliferous material, containing an excess of fuel in lump form, is screened to separate the larger lumps of fuel (exceeding half an inch in diameter) and to form a fine product containing sufficient carbon for sintering.

—W. E. F. P.

Metals; Process and apparatus for the separation of —. [Recovery of silver from photographic solutions.] Ges. für angew. Photographie m.b.H., Freiburg. Ger. Pat. 302,279, June 1, 1916.

For the recovery of metals, particularly of silver from photographic solutions, a precipitating metal is used in the form of balls or rollers with smooth surfaces. These are kept in continual frictional motion in the solution, which may be contained in a rotating apparatus or shaking vessel.—C. A. M.

Pyrites cinder; Process for the desulphurisation, decinification, and agglomeration of —. G. Hentschel, Duisberg-Meiderich. Ger. Pat. 302,281, Jan. 16, 1917.

Pyrites cinder is desulphurised by heating it strongly in a rotary tube furnace. It then passes into a second similar furnace where it is mixed with carbon and heated by an air blast, the zinc being distilled. The hot gases from this tube circulating around the desulphuriser heat it and are themselves cooled. The residue is mixed with fine iron ore or blast-furnace or other similar dust and sintered to form porous blocks in a third rotating tube furnace.—F. C. Th.

Silicon coatings; Method for producing — by treating the object to be covered in the hot state with halogen or halogen-hydrogen compounds of silicon. Böhmische Elektrizitäts A.-G., Vienna. Ger. Pat. 302,305, Apr. 4, 1915.

Iron and other metals are protected from acid and other corrosion by formation of a surface layer of silicon or a silicon alloy. Red hot iron reacts with silicon tetrachloride, forming ferric chloride and silicon. Other halogen compounds of silicon may be substituted. Substances which do not react with the silicon compounds are first coated with a reactive substance.—F. C. Th.

Tools with sharp edges; Annealing of —. A. Pfretzschner, Munich. Ger. Pat. 302,359, Nov. 19, 1915.

The hydrogen given off from an electrolytic cell may if the tension is sufficiently great be hot enough to cause the metallic cathode to glow. If the tool to be annealed is made the cathode it can be raised to any desired temperature. The edges must be protected, preferably by a carburising coating, from the direct action of the hydrogen which would otherwise blunt them. The insulating coating allows only the unprotected parts to act as cathode, the edges being heated by conduction.

F. C. Th.

Iron, copper, and brass; Method of preparing coatings [of bismuth] on metals, especially on —. Chem. Fabr. auf Actien, vorm. E. Schering. Ger. Pat. 302,816, June 23, 1916.

The metals are treated by any ordinary process, such as dipping, rubbing, or spraying, with a solution of bismuth iodide or bromide in the alkali iodides or bromides and the corresponding acids. A layer of bismuth is deposited in the cold as a

matt deposit which is firmly adherent. The iodide solution is more satisfactory than the bromide in the case of copper.—F. C. Th.

Etching of printing-plates; Process for the electrolytic —. H. Strecker, Munich. Ger. Pat. 302,902, Mar. 31, 1916.

THE electrodes are separated by such a short distance as almost to produce short-circuiting, in order to produce an etched surface of almost mirror-like brilliance. The nearness of anode and cathode causes the etching to be a lattice pattern. The plate is carried in a movable support in the bath so that the cathode may occupy any desired relative position. The process is applicable to the etching of plates with or without a coating on the surface.—F. C. Th.

Metallic objects containing fine pores; Process for increasing the density of —. Berliner Maschinenbau A.-G. Ger. Pat. 302,934, Sept. 2, 1916.

THE objects are galvanised electrolytically under high pressure—greater than that to which the article will later be subjected. Under this pressure the electrolyte penetrates the pores as it would not do at ordinary pressures.—F. C. Th.

Ore concentrating tables. E. Trestrail, Redruth. Eng. Pat. 115,494, May 10, 1917. (Appl. No. 6672 of 1917.)

Distilling metallic ores and other materials containing metals; Process for —. D. B. Jones, Chicago, Assignee of C. H. Fulton and T. M. Bains, jun., St. Louis, U.S.A. Eng. Pat. 112,924, Aug. 10, 1917. (Appl. No. 11,499 of 1917.) Under Int. Conv., Jan. 24, 1917.

SEE U.S. Pat. 1,212,339 of 1917; this J., 1917, 1240.

Sintering fine ores, flue-dust, purple ore, iron filings and the like; Process for —. C. Giesecke, Harzburg, Germany. Eng. Pat. 115,441, Oct. 4, 1916. (Appl. No. 14,059 of 1916.)

SEE U.S. Pat. 1,205,944 of 1916; this J., 1917, 89.

Process for the fractional separation of tarry substances such as pitch or steel works tar and tar oils from superheated crude gases. Ger. Pat. 303,195. See IIa.

Rust-proofing composition and process of making same. U.S. Pat. 1,263,395. See XIII.

XI.—ELECTRO-CHEMISTRY.

Electrical endosmose. II. T. R. Briggs, H. S. Bennett, and H. L. Pierson. J. Phys. Chem., 1918, 22, 256–272.

AN electrical endosmometer is described which has been used in the measurement of the rate of flow of solutions through diaphragms of carborundum, alundum, powdered glass, and gelatin and agar-agar jellies. Experiments made with dilute solutions of sodium hydroxide and hydrochloric acid show that the endosmotic flow is towards the cathode in alkali and towards the anode in acid solution. This reversal occurs with diaphragms of carborundum and alundum and also with jelly diaphragms, but in the case of powdered glass the flow is towards the cathode in both acid and alkaline solution. The effects obtained with various copper salts are described and interpreted in terms of the adsorption of the ions by the diaphragm.

Observations made on acid and alkaline solutions of Eosin, Crystal Ponceau, Safranin and Methylene Blue are also described and discussed in reference to the adsorption theory of dyeing. (Compare J. Chem. Soc., July, 1918.)—H. M. D.

Galvanic batteries; Restoration of exhausted —. E. Stern. Z. Elektrochem., 1918, 24, 91–93.

EXAMINATION of exhausted Leclanché cells used in telephonic work and for flash lamps showed that the zinc containing vessel was practically worn out and the carbon electrode was covered with ammonium chloride crystals and in many cases disintegrated. On washing the carbon electrodes and placing them in a 20% paste of ammonium chloride and sawdust contained in a fresh zinc container, it was found that the repaired cells fall into three groups, (1) those with an EMF of above 1 volt, (2) those with an EMF of 0.8–1.0 volt, and (3) those with EMF below 0.8 volt. The two first groups of cells are suitable for further use.—J. F. S.

PATENTS.

Electrolytic cells particularly adapted for the electrolysis of salt or similar material. N. Statham, Hastings-on-Hudson, New York. Eng. Pat. 114,974, Sept. 26, 1917. (Appl. No. 13,883 of 1917.)

AN electrolytic cell is composed of a concrete cell body with metallic cathode members extending into it, and connected to cathode plates substantially free from direct contact with the cement; strengthening stay rods are arranged at the outside of the cell to hold the members together whilst minimising undesirable expansion strains. Carbon anode posts, with their exposed portions protected by an insulating covering of vulcanised rubber, are built into the cell, and movable carbon anode plates are connected with the anode posts by means of double-tapered graphite pins, so that the plates are supported in close co-operation with the cathode diaphragms at the sides of the cell.—B. N.

Electrolysis; Apparatus for —. P. A. Emanuel, Aiken, S.C. U.S. Pat. 1,233,314 Apr. 16, 1918. Date of appl., Dec. 24, 1917.

AN electrolytic vessel comprises a container formed of two hemispherical sections with flanges connected together but insulated from each other; there is a perforated metallic disc in each section and a partition separates the sections and discs. The partition does not interfere with electrolysis, but serves to prevent the commingling of the evolved gases. Two substantially hemispherical tanks are arranged above the container, and are connected by valved pipes to the respective sections, with means for placing the container and tanks under pressure. The electric circuit includes the tanks, container sections, perforated discs, and electrolyte.—B. N.

Furnaces; Electric — and transformers for use therewith. The British Electric Transformer Co., Ltd., and F. E. Berry, Hayes, Middlesex. Eng. Pat. 115,247, Jan. 31, 1917. (Appl. No. 1588 of 1917.)

A THREE-PHASE electric furnace is provided with upper electrodes and lower laterally-arranged electrodes, so connected to the associated transformer, that not only is the order of the electrodes in the upper set the reverse electrically of that in the lower lateral electrodes, but each upper electrode is directly opposite a lower lateral electrode as seen in plan. Means are provided whereby the lower lateral terminals can, when desired, be temporarily short-circuited either at the furnace or at

the transformer windings. By this arrangement good distribution and control of the heat in the furnace can be ensured, together with thorough mixing of the charge.—B. N.

Electrodes in electric furnaces; Preventing the oxidation or wasting of the —. W. B. Hamilton, Sheffield, and J. Holland, Grindelford, Derby. Eng. Pat. 115,705, May 25, 1917. (Appl. No. 7519 of 1917.)

The oxidation or wasting of electrodes in electric furnaces is prevented by building an elongated keystone brick or block, made in one or several pieces, into the roof or walls of the furnace. The block is provided with a central passage, of a bore only slightly larger than the diameter of the electrode passing through the same, and is of sufficient length to enclose the glowing portion of the electrode when the latter is withdrawn from the furnace.—B. N.

Furnaces; Electric —. O. Sahlin, London. Eng. Pat. 115,719, June 13, 1917. (Appl. No. 8478 of 1917.)

The electrodes, arranged in one or more pairs, enter through the side walls, approximately opposite the charging door, and are carried by water-cooled boxes secured to the furnace by cotter. The upper electrode of each pair is inclined downwards, while the lower electrode is substantially horizontal, and both are in the same vertical plane. The furnace is heated at the commencement by free-burning arcs formed between the upper and lower electrodes, the inclined electrode of each pair being then advanced further into the furnace so that the free-burning arcs are forced towards the hearth. The charge is introduced, and when some of it has been melted, the furnace is tilted and some or all of the lower horizontal electrodes withdrawn, so that direct arcs are formed between the corresponding upper electrodes and the bath. When two- or three-phase alternating currents are employed, the horizontal electrodes are connected to a conducting plate at the bottom of the furnace, so placed that when current is conveyed by this plate, the voltage between the bath and an inclined electrode is usually about half the normal voltage between two inclined electrodes.—B. N.

Gases; Treatment of — in electric furnaces. E. Edwin, Assignor to Norsk Hydro-Elektrisk Kvaestofaktieselskab, Christiania, Norway. U.S. Pats. (a) 1,263,289 and (b) 1,263,390, Apr. 23, 1918. Dates of appl., Aug. 29, 1916, and Feb. 14, 1918.

(a) The hot gases from an electric arc furnace are made to expand continuously whilst passing to an absorption device, thus cooling them. The mechanical energy which is developed is utilised in a hot air turbine to drive a rotary compressor for compressing the gases to the pressure at which they are used in the arc furnace, and producing the circulation of the gases in the system. The arc is thus stabilised, and velocity and energy production are maintained in accordance with the furnace operation. (b) The gases are circulated in a closed system between an electric arc furnace and an absorber, the latter being maintained under a pressure higher than that of the furnace. The pressure of the gases is diminished between the absorption plant and the furnace, thereby transforming their heat energy into mechanical work in a hot air turbine, the latter driving a rotary compressor working approximately at the same difference of pressure as the turbine, and supplying the circulating gases to the

absorption plant. The cooled gases, after leaving the absorption plant, are preheated by the hot furnace gases before being compressed.—B. N.

Anode. H. R. Swartley, jun., Manhasset, N.Y., Assignor to Davis-Bourmonville Co., Jersey City, N.J. U.S. Pat. 1,263,959, Apr. 23, 1918. Date of appl., Feb. 25, 1916.

The anode is provided with a permanent continuous surface of sprayed nickel.—B. N.

Electrolytic apparatus for generation of oxygen and hydrogen. I. H. Levin, Newark, N.J., U.S.A. Eng. Pat. 107,366, Jan. 3, 1917. (Appl. No. 117 of 1917.) Under Int. Conv., June 3, 1916.

SEE U.S. Pat. 1,199,472 of 1916; this J., 1916, 1224.

XII.—FATS; OILS; WAXES.

Para rubber seed; Oil-content, keeping qualities, and commercial possibilities of —. F. G. Spring and F. W. F. Day, Agric. Bull. Fed. Malay States, 1918, 6, 231–244.

The yield of rubber seed on Malay plantations approximates to 300 lb. per acre per annum; about 37% of the seed consists of shell, as compared with 22% of shell in the English chestnut and 16% in the acorn, and to produce a ton of kernels 427,000 seeds are necessary; the seeds, either whole or decorticated, can be stored satisfactorily in bags after a preliminary sun-drying. On extraction with petroleum ether the dried meal from the kernels and the whole seeds respectively yield approximately 51% and 29% of oil. The oil possesses rather less drying power than linseed oil but should easily find industrial application. Samples of the oil hitherto examined have had sp. gr. at 15°/15° C. 0.925–0.930, acid value 10.7–40.9, saponification value 188.5–192.1, and iodine value 128.3–143.3. The residual cake after the removal of the oil by pressing, is a useful cattle food although care is required in its use for immature animals.—D. F. T.

Spinacene and some of its derivatives. A. C. Chapman. Chem. Soc. Trans., 1918, 113, 458–466.

When the hydrocarbon spinacene from shark-liver oil is distilled over sodium, especially if the pressure is allowed to rise to 45 mm., partial decomposition occurs and a cyclo-dihydroterpene, $C_{10}H_{18}$, b.pt. 170°–175° C. at atmospheric pressure, sp. gr. at 20°/20° C. 0.8125, and refractive index 1.4565 at 20° C., can be separated from the decomposition products. Spinacene is therefore more suitably purified by distillation under a maximum pressure of 10 mm., when it is found to have the composition $C_{15}H_{24}$, b.pt. 260° C. (corr.) at 9 mm., sp. gr. at 15°/15° C. 0.8610, and refractive index 1.4965 at 20° C. Its hexahydrochloride melts at 126° C. and its hexahydrobromide at 132° C.; the former when heated under reduced pressure undergoes loss of hydrogen chloride with formation of a hydrocarbon quite distinct from the original spinacene. The formula $C_{15}H_{24}$ previously attributed to spinacene (Chapman, this J., 1917, 392) is withdrawn.

—D. F. T.

Resins; Rapid determination of — in soap. V. Fortini. Annali Chim. Appl., 1918, 9, 102–108.

TWITCHELL's method of determining rosin in soap has the drawbacks that it shows an apparent rosin content with pure soaps, and that it is not applicable to resins other than colophony. These drawbacks are obviated in the following method, which

is based on the fact that nitrated resins are insoluble in petroleum spirit. Two grms. of the mixed fatty and resin acids from 25 grms. of the soap is treated in a separating funnel with 50 c.c. of petroleum spirit (b.pt. 40° to 70° C.), the presence of resin acids being indicated by incomplete solution. Ten c.c. of nitric acid, prepared by mixing 25 c.c. of fuming nitric acid (sp. gr. 1.52) and 75 c.c. of ordinary nitric acid (sp. gr. 1.48) and adding a few crystals of urea to destroy nitrous acid, is then introduced in successive small portions. The mixture is shaken for 2 to 3 mins., then allowed to stand, the acid layer drawn off, and the petroleum spirit shaken with an additional 5 c.c. of the nitric acid, which is also drawn off. The petroleum spirit layer is then washed successively with ordinary nitric acid, and with water and filtered, the filtrate evaporated, and the residue of fatty acids dried and weighed. The quantity of resin acids is obtained by difference. The results thus obtained agree within about 1% of theory in the case of mixtures of 5 to 20% of rosin with saturated fatty acids or oleic acid.—C. A. M.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Conifer resin; Fat content of —. C. G. Schwalbe and W. Schulz. Chem.-Zeit., 1918, 42, 229—230.

PINE wood yields about 11.4% of resin containing 27% of fatty acids as determined by the Twitchell esterification method; the heart wood gives 16% of crude resin containing 3.5% of fatty acids, and the sap wood 2.4% of resin containing 1.2% of fatty acids.—W. P. S.

Oil varnishes; Examination of —. H. Smit-Addens. Olien & Vetten, 1917, 2, 23, 58, 80. Z. angew. Chem., 1918, 31, Ref., 142.

For the estimation of the volatile thinners a weighed portion is steam-distilled in a current of carbon dioxide. The distillate is transferred to a burette containing 10 c.c. of water, and the volume of thinners is read off, whilst the aqueous layer is examined for smell and acid reaction. The specific gravity of the distillate can be determined in the case of turpentine by the method of floating a drop in dilute alcohol, while in the case of petroleum spirit a pycnometer is employed. A quantitative examination (see below) is necessary since all other substitutes have a greater "thinning" power than petroleum spirit. To estimate the non-volatile constituents the condensed water is removed from the distillation flask as far as possible, 96% alcohol and excess of N/1 alkali are added, and the mixture is boiled under a reflux condenser for 20 minutes. The alcohol is then partly evaporated off and the liquid transferred to a separating funnel, the flask being rinsed out with petroleum ether and alcohol. The soap solution is extracted twice with petroleum ether and the extract evaporated, dried at 105° C. and weighed as copal resin. The soaps of the softer resins, Manika, Congo, and Brazilian copals are not so easily hydrolysed and these resins are estimated along with the rosin acids. In the case of Dammar resin, a portion is easily saponifiable whilst another is unsaponifiable, the latter being partly soluble in petroleum ether whilst the former is soluble in ether only. Should Dammar be suspected, the soap is further extracted with ether and the extract evaporated when a light coloured residue indicates its presence; extraction with chloroform or carbon tetrachloride will serve to separate copal. The extracted soap residue is then acidified with dilute nitric acid and shaken twice with petroleum ether, nearly neutralised with alkali, and examined for metals in the usual way. The acid petroleum ether containing rosin acids and fatty acids is examined qualitatively by the Storch-Morawski test and quantitatively by Twitchell's method. The hydroxy fatty acids which cling to the walls of the separating funnel are dissolved in a mixture of equal parts of alcohol and carbon tetrachloride and calculated to oleic acid. Examination of the aqueous layer and of the water from the initial distillation will determine the presence of volatile and soluble substances (phenol). In the case of films of paints and varnishes, a separation into pigment and vehicle is obtained by means of suitable solvents, when these constituents can then be examined.

The specific gravity of the volatile "thinners" (see above) is determined by introducing a drop into alcohol of about 70% strength (sp. gr. 0.87 at 15° C.). If the drop floats or sinks rapidly, it is safe to assume that the distillate is not pure turpentine, but if the distinction is not so sharp, addition of water or alcohol will permit of the specific gravity being determined. A second drop serves for the determination of the refractive index and if the result therefrom agrees with that from

the specific gravity and the smell is found to be normal, no further examination is necessary. In other cases Herzfeld's method is used to obtain a separation into turpentine, petroleum spirit, and homologues of benzene.—A. de W.

Vulcanised rubber goods; Process of separating fibrous materials from —. W. Golombek, Spandau. Ger. Pat. 303,171, June 21, 1916.

THE material is finely divided and stirred for a short time with slightly warm water; the fibres are wetted more easily and sink, whilst the particles of rubber float, and are skimmed off.—A. de W.

Method of treating finely-subdivided material [for rubber mixings, etc.]. U.S. Pat. 1,263,082. See XIII.

XV.—LEATHER; BONE; HORN; GLUE.

Leather; Determination of free sulphuric acid in —. H. Strunk and O. Matthes. Z. angew. Chem., 1918, 31, 61—63.

THIRTY c.c. of magnesium nitrate solution (containing about 0.2 gm. MgO) is heated in a round-bottomed flask until an almost dry residue remains; 5 grms. of the leather and a few c.c. of 30% nitric acid are added and the mixture is heated on a water-bath until reaction ceases. Fifty c.c. of concentrated nitric acid is then added, the mixture boiled on a sand-bath for 2 hrs., heated over a flame until all the nitric acid has been expelled, cooled, again heated with concentrated nitric acid, and evaporated. The dry material is strongly heated to decompose nitrates and expel nitrous fumes from the flask, and the almost white residue is dissolved in 30 c.c. of N/2 hydrochloric acid, filtered if necessary, and titrated with N/10 sodium hydroxide solution, using phenolphthalein as indicator. Another portion of 30 c.c. of the magnesium nitrate solution is evaporated, heated to decompose the nitrate, the residue dissolved in N/2 hydrochloric acid, and titrated with sodium hydroxide solution. Less sodium hydroxide solution will be required in this titration than in the case of the residue from the mixture containing the leather if free sulphuric acid is present; the sulphuric acid combines with a portion of the magnesium oxide, and the difference in the two titrations is a measure of the quantity of free acid present.—W. P. S.

Gelatin; Stoichiometrical character of the action of neutral salts on the swelling of —. J. Loeb. J. Biol. Chem., 1918, 34, 77—95.

THE limiting concentrations of neutral salts which just inhibit the additional swelling of gelatin, sodium gelatinate, or gelatin chloride (compare this J., 1918, 274 A), are dependent on the valency but not on the nature of the ions. The limiting inhibiting concentration of salts with univalent ions is twice as high as that of salts with divalent ions. Antagonistic salt action occurs when gelatin salts with univalent ions are transformed into salts with divalent ions. (See further J. Chem. Soc., July, 1918.)—H. W. B.

Gelatin solutions; Influence of neutral salts on the viscosity of —. J. Loeb. J. Biol. Chem., 1918, **34**, 395—413.

THE viscosity of solutions of gelatin which has been previously treated with neutral salts is affected in a manner similar to that observed in the case of the swelling effect previously recorded (see preceding abstract). In the experiments with gelatin and sodium gelatinate, the viscosity is increased by cations, whilst with gelatin chloride only the anion has any effect. (See further J. Chem. Soc., July, 1918.)—H. W. B.

Gelatin; Effects of electrolytes on — and their biological significance. IV. Precipitation of gelatin by mixtures of salts. W. O. Fenn. J. Biol. Chem., 1918, **34**, 415—428. (Compare this J., 1918, 216 A, 274 A.)

THE amount of sodium chloride or sulphate required to precipitate gelatin from a solution containing an acid, alkaline, or neutral salt besides gelatin, depends on the nature of the ions which are present. Acids promote precipitation of the gelatin whilst alkalis usually have the reverse effect. (See further J. Chem. Soc., July, 1918.)—H. W. B.

PATENTS.

Impregnating material for leather, leather substitute, fabrics, etc.; Manufacture of —. F. Natho, Hamburg. Ger. Pat. 302,158, Apr. 14, 1915.

BURGUNDY, coumarone or similar resins are heated with animal fats, and when the mass is brought to a certain consistency and temperature, sulphur is added for the purpose of vulcanisation, and then the mixture is allowed to cool and suitably diluted. This filling material is especially good for leather, which it impregnates quickly and renders permanently waterproof and flexible. Equally good products are obtained with leather that is not fully tanned, and poor leathers can be improved so as to be equal in value for many purposes to the best grades.—J. C. W.

Waterproof [fibrous] composition and process for making such composition [from spent bark]. U.S. Pat. 1,263,823. See V.

XVI.—SOILS; FERTILISERS.

Soils; Mechanical and physical analysis of —. G. Richter. Bied. Zentr., 1918, **47**, 49—52.

IN the mechanical examination of soils, preliminary treatment, such as ignition, oxidation with bromine, etc., should be avoided as it destroys the colloids and alters the character of the soil. Kopecky's trituration method appears to be the best of the mechanical methods. As regards methods for determining the hygroscopic character of soils, it is found that Breitenbach's method gives the highest results, those obtained by Mitscherlich's method (this J., 1910, 1217) are lower, whilst Atterberg's method gives still lower results. In the author's opinion, the chief value of the results obtained in the determination of the hygroscopic character of soils lies in the indications they give of the nature and size of the soil particles. (See also J. Chem. Soc., July, 1918.)—W. P. S.

Aluminium as a factor influencing the effect of acid soils on different crops. B. L. Hartwell and F. R. Pember. J. Amer. Soc. Agron., 1918, **10**, 45—47. Bull. Agric. Intell., 1918, **9**, 420—421.

THE toxicity of so-called acid soils is not due to the acid alone, as is shown by the different effects in

seedlings of barley and rye. Further, whilst the addition of acid to an ordinary nutrient solution caused similar effects with rye and barley seedlings, the aqueous extract of an acid soil affected the two kinds of seedlings very differently. This soil extract thus contained a substance not present in the ordinary nutrient solutions, and aluminium being present in large quantities in the soil extract a study was made of the effects of this element either alone or in combination with other substances on plant growth. The results indicate that aluminium must be considered as an important factor in the injurious effects of acid soils. The determination of the "active" aluminium of a soil may, therefore, prove as useful as the determination of its acidity, and the lime requirements of a soil may be due to the need of lime to precipitate the toxic aluminium just as much as to the need of lime to neutralise its acidity.—W. G.

Soil acidity; Action of neutral salts on humus and other experiments on —. L. J. Gillespie and L. E. Wise. J. Amer. Chem. Soc., 1918, **40**, 796—812.

TRULY acid soils are common and widely distributed in the United States. The hydrogen electrometer provides the most trustworthy method for the measurement of the hydrogen ion concentration of soils; litmus paper used without suitable precautions can yield seriously inaccurate results. It is possible that the relatively high hydrogen ion concentration of some soils may account for their comparative freedom from potato scab disease. (See also J. Chem. Soc., July, 1918.)—D. F. T.

Phosphoric acid; Use of "mine run" phosphates in the manufacture of soluble —. W. H. Waggaman and C. R. Wagner. J. Ind. Eng. Chem., 1918, **10**, 353—355.

PHOSPHATE rock as mined can be successfully treated by the electric furnace method (Ross and others, this J., 1916, 1154; 1917, 134), and the necessity of preparing and washing the rock is thus obviated, and the waste due to the discarding of low-grade material avoided. Experiments were made with a 500-lb. charge, mixed with coke, and with sand when silica was deficient. This was smelted in the furnace for 3 hours, and a yield of about 98% of the phosphorus was obtained. The cost of producing phosphorus pentoxide from "mine run" rock is estimated at from \$3.75 to \$6.50 less than from high-grade phosphates. Results are also given showing that by using the phosphorus pentoxide thus obtained to treat another batch of phosphate rock to form "double superphosphate," the cost of production compares favourably with that of the production of ordinary superphosphate by the sulphuric acid process under the present shortage of sulphuric acid.—W. F. F.

Thomas slag; Determination of citric-soluble phosphoric acid in —. R. Hartleb. Z. angew. Chem., 1918, **31**, 61.

A DILUTE solution of nitric acid may be used in place of the citric acid solution usually employed for the determination of "citric-soluble phosphoric acid." A solution of which 1 c.c. is equivalent to 0.164 c.c. of N/1 nitric acid gives results identical with those obtained by the use of 2% citric acid solution.

Fertilising value of activated [sewage] sludge. G. G. Nasmith and G. P. McKay. J. Ind. Eng. Chem., 1918, **10**, 339—344.

TO determine the fertilising value of activated sewage sludge and to compare it with other ferti-

lisers, experiments were made with a number of vegetable crops. Ordinary manure, activated sludge, sludge from an old bed, "Brush filter" humus, and tank sludge, air dried in each case, were used on similar plots, and comparative results are given showing the variation of the yield with different manures and with different vegetables. The increase in yield due to activated sludge over farmyard manure varied from 40% with radishes to 554% with Weatherfield onions, beets and tomatoes also giving a very high yield. The plants also reached maturity earlier than those grown with other fertilisers.—W. F. F.

Treatment of washing water in the production of artificial silk. De Chardounet. See V.

PATENTS.

Nitrate of ammonia; Treatment of —. E. Bergve and J. Sundby. Assignors to Norsk Hydro-Elektrisk Kvaestofaktieselskab, Christiania, Norway. U.S. Pat. 1,263,263, Apr. 23, 1918. Date of appl., May 8, 1917.

AMMONIUM nitrate, alone or mixed with plaster of Paris, is moistened with a liquid containing inorganic material which becomes viscous on the addition of water; and the mixture is agitated while being dried at 90°–110° C.—W. E. F. P.

Fertiliser; Process of preparing a — which remains permanently in a state suitable for distribution. Farb. v. vorn. Meister, Lucius, u. Brüning. Ger. Pat. 304,184, Oct. 6, 1916.

IMPURE urea obtained from crude calcium cyanamide is mixed with calcium carbonate, in particular with the residue of calcium carbonate left in the preparation of urea from cyanamide. In this way a fertiliser containing about 20% of nitrogen is obtained in the form of a powder which does not cake on exposure to air.—C. A. M.

XVII.—SUGARS; STARCHES; GUMS.

Molasses; Water content of true final —. H. C. Prinsens Geerlign. Intern. Sugar J., 1918, 20, 214–218.

As a corollary of the author's theory of the formation of final molasses (see this J., 1895, 667; 1918, 316 A), it follows that there is an optimum water content to which the massecuite must be reduced in order to attain the maximum exhaustion in practice. If more water is left in the massecuite than corresponds with the real water content of the hydrated combination of sucrose, reducing sugars, and salts (of which, according to the theory, molasses is composed), the excess water retains free sucrose in solution, and the final molasses is not fully exhausted. If, on the other hand, the concentration has been conducted beyond the optimum point, the viscosity of the product may be so greatly increased as to retard crystallisation and render the work of separation very laborious. To determine the optimum water content, molasses is diluted with water and divided into a number of portions, one of which is left untouched, whilst the others are evaporated each to gradually increasing stages of concentration, so as to obtain a series of molasses solutions, the first of which contains a higher and the last a lower water content than that corresponding to the optimum value. These solutions are heated in a water-bath to 100° C., and to each is added 20% of sucrose crystals (sifted free from "dust," and heated to the same temperature to pre-

vent sudden cooling of the mixture). After gradually lowering the temperature of the bath until after 3 days it reaches 45° C., the crystals are separated from the molasses, and determinations of sucrose, water content, and purity made in each case. When the dilution has been excessive and free sucrose has been dissolved, the purity of the molasses will be higher than at first; whilst when the water content is below the optimum the purity of the molasses will be lower. In the samples in which the water content corresponds with the optimum value, the purity of the molasses will have remained constant, and the true water content of the hydrated combination for the particular molasses under examination may then be calculated. From preliminary experiments using this method and from practical tests carried out in the sugar-house, it is concluded that the concentration to which molasses should be boiled to obtain a fully exhausted molasses is about 16% of water (i.e., 84% dry substance as indicated by the refractometer). A final molasses at this density may contain 160–174 parts of sucrose per 100 of water, depending upon the purity of the particular product.—J. P. O.

[Beet] molasses; Polarisation of acidified solutions of —. Andriik. Böhm. Zuckerind., 1918, 42, 347. Chem.-Zeit., 1918, 42, Rep., 55.

NUMEROUS experiments showed that whilst some acids, such as hydrochloric and sulphuric acids, give rise to hydrolysis and also (apart from this) raise the polarisation, others, such as boric and acetic acids, have little or no action in either of these respects, and others, including phosphoric and hydrofluosilicic acids, give rise to hydrolysis but do not otherwise affect the polarisation; acids of the last group often exert a considerable decolorising influence. In inverted solutions acids diminish the levorotation by their influence on the amino-acids; in the case of neutral or faintly acid molasses there occurs also a transformation of saccharin into saccharinic acid, which gradually increases the levorotation to a certain extent. On these results the author bases two methods of clarification, applicable to very dark molasses before and after inversion. After a preliminary defecation with basic lead acetate, a mixture of phosphoric and phosphotungstic acids is used in one case, and in the other acetic acid, sodium sulphide, and zinc dust (to precipitate the lead).—J. H. L.

Molasses; Determination of sucrose in cane — by Walker's method, using dry basic lead acetate for the preliminary clarification. H. S. Walker. Intern. Sugar J., 1918, 20, 239–240.

IN the determination of sucrose by double polarisation 0.5–1.0% less sucrose is found when the preliminary clarification is effected by Horne's method of using dry basic lead acetate than when a solution of basic lead acetate is used. Experiments carried out with solutions containing known amounts of sucrose, reducing sugars, and impurities, corresponding in composition to ordinary molasses, showed that when the dry reagent is used the results approximate closely to the truth, being only about 0.09% too low; whereas when a solution of the reagent is used the value obtained may be about 0.7% too high owing to the error due to the volume of the lead precipitate. The following procedure involving dry clarification is recommended: Twice the normal sugar weight of the sample is dissolved in water, made up to 300 c.c., clarified with 15–20 grms. of dry basic lead acetate, and filtered; 75 c.c. of the filtrate is transferred to a 100 c.c. flask, 20 c.c. of phosphoric acid (containing 100 grms. per litre) added, the volume made up to 100 c.c., and the liquid filtered. A pale yellow liquid is obtained,

the direct reading of which can be made in a 400 mm. tube. Another 75 c.c. is placed in a 100 c.c. flask, together with 2 c.c. of hydrochloric acid (1:1) to neutralise the alkalinity due to dissolved basic lead acetate, and the inversion carried out by Walker's method (this J., 1917, 153). After heating to 65°–70° C., 10 c.c. of hydrochloric acid (1:1) is added, and after at least 15 minutes the liquid is cooled, made up to bulk, filtered, and the inversion reading taken in a 400 mm. tube, the sucrose being calculated according to the formula:

$$\frac{D-1}{142.0-0.5^{\circ}T}$$

The results are accurate to within 0.07%, and are independent within reasonable limits of the amount of lead reagent used. Pellet's sulphurous acid method (this J., 1911, 64; 1913, 155) was found to yield results about 0.44% too high, and is uncertain owing to the danger of inversion while taking the direct reading. In the author's method the excess of phosphoric acid remaining in solution is the maximum possible without inversion occurring while taking the direct reading, and although its influence upon the levorotation of the reducing sugars is not so pronounced as that of 5 c.c. of hydrochloric acid, the difference is insufficient to introduce any appreciable error.—J. P. O.

Molasses; Gravimetric determination of glucose (reducing sugars) in —. R. S. Norris and A. Brodie. Intern. Sugar J., 1918, 20, 238–239.

ALTHOUGH in some samples of molasses non-sugar reducing substances precipitable by normal lead acetate may be absent, or only present in a negligible amount, clarification by means of this reagent, previous to the determination of the reducing sugars by means of Fehling's solution, is generally required. In order to remove the excess of the lead reagent disodium phosphate is recommended in preference to other salts, as it effects complete precipitation, and the excess left in solution has no action upon the copper reduction. Potassium oxalate (*cf.* Meade and Harris, J. Ind. Eng. Chem., 1917, 8, 504) increases the reduction; the use of sodium carbonate leads to low results, owing apparently to precipitation of some of the reducing sugars by the basic lead acetate formed on its addition; phosphoric acid, on the other hand, gives high results on account of its hydrolysing action on the sucrose. Varying the amount of sodium hydroxide in the Fehling's solution was not found appreciably to influence the amount of cuprous oxide precipitated.—J. P. O.

Lime in products of [beet] sugar factories; Determination of —. A. Vermehren. Z. Ver. deut. Zuckerind., 1917, 42, 610. Z. angew. Chem., 1918, 31, Ref., 81.

BLANCHER's potassium palmitate solution (see this J., 1912, 555; 1913, 158), applied to the determination of the lime-content of beet sugars, massecuites, and molasses, gave results accurate enough for practical purposes. 25 grms. of the material is dissolved and made up to 100 c.c. with water containing phenolphthalein. An aliquot part of this solution, depending on the colour, is diluted to 100 c.c., neutralised by titration with N/10 hydrochloric acid (thus furnishing the "alkalinity"), then heated to boiling, and after cooling titrated with the palmitate solution.—J. H. L.

PATENTS.

Sugar and the like; Apparatus for evaporating —. J. T. Davis, Alameda, Cal. U.S. Pat. 1,263,747, Apr. 23, 1918. Date of appl., July 11, 1916.

THE evaporator comprises a vapour chamber, a conical plate therein, a steam chamber immediately

beneath it, of which the conical plate forms the upper side, an annular chamber situated at the top of the conical plate for containing the liquid to be evaporated and having an outlet through which the liquid is discharged on to the plate, a trough into which the liquid is discharged from the conical plate, a conveyor in the trough and a steam chamber on the under side, a vertical tube containing a conveyor which receives the material delivered from the first conveyor, a steam chamber around the tube, and means for operating the conveyors and supplying steam to the steam chambers simultaneously.—J. F. B.

Adhesive composition [gum] and process of making same. W. Alexander, Assignor to National Gum and Mica Co., New York. U.S. Pats. (A) 1,263,634 and (B) 1,263,635, Apr. 23, 1918. Dates of appl., Feb. 8 and Sept. 18, 1917.

(A) A SOLUTION of a gum of the gum arabic type is mixed with borax or a soluble boron compound and the mixture is dried and powdered. (B) The gum and boron compound are powdered or granulated and intimately mixed in the dry state.

—J. F. B.

XVIII.—FERMENTATION INDUSTRIES.

Wine; Detection of cider in —. P. Medinger and F. Michel. Chem.-Zeits., 1918, 42, 230.

FIFTEEN c.c. of the wine is shaken with a few c.c. of concentrated sodium nitrite solution; pure wines give a bright yellow or yellowish-brown coloration, whilst cider or perry is coloured dark brown or brownish-black and a brownish-black precipitate separates. This precipitate is insoluble in water, alcohol, ether, etc., but dissolves in alkali solution giving a red solution. Wines when treated with both sodium nitrite and potassium hydroxide give a yellow coloration, whilst cider and perry and mixtures of the same with wine yield a pure red coloration.—W. P. S.

Enzyme formation. VI. M. Jacoby. Biochem. Zeits., 1918, 86, 329–336.

WHILST leucine promotes the formation of urease in the case of *B. coli* it inhibits the sugar-fermenting action. (See also J. Chem. Soc., July, 1918.)

—S. B. S.

Phosphoric acid esters of carbohydrates (zymophosphate); Preparation of — by means of living yeasts. H. Euler. Biochem. Zeits., 1918, 86, 337–342.

NEUBERG has found that yeasts in the presence of toluene could only bring about esterification of 7–8% of phosphate, whereas the author, working under the same conditions, found complete esterification. The difference in results may be due to two causes, viz., excess of toluene inhibits the action, and not all bottom beer yeasts are active in this respect. The author also confirms the statement of Harden and Young that only a small amount of zymophosphate is produced by the action of the hydroxyacetone on phosphates. (See also J. Chem. Soc., July, 1918.)—S. B. S.

Use of Sorghum vulgare (millet) in the cellulose industry. Haas. See V.

Some constituents of the American grape-fruit (Citrus decumana). Zoller. See XIXa.

PATENT.

Diastatic product; Process for producing —. J. Takamine, New York. U.S. Pat. 1,263,817, Apr. 23, 1918. Date of appl., Aug. 11, 1916.

A CULTURE medium is agitated in a tumbling drum and, during agitation, the medium is sown with a liquid containing in suspension the spores of a fungus capable of producing diastatic enzymes, and the mixture is agitated under incubating conditions so as to secure the contact of air with the medium. The culture medium contains an antiseptic composed of 10 parts of sodium fluoride and 17 parts of salicylic acid, added in the proportion of 1 part of antiseptic to 500–1000 of medium.—J. F. B.

XIXA.—FOODS.

Wheat; Substitutes for — in war bread. Balland. Comptes rend., 1918, 166, 846–849.

FURTHER experiments (compare this J., 1917, 608) have been performed testing the use of various flours as substitutes for wheat flour in making war bread. The results indicate that the various substitutes act differently on the wheat gluten. Manioc flour used to the extent of 10 or 20% lowers to 28 or 24% the gluten of wheat flour containing 33%. Under the same conditions the flour from maize, barley, or rice gives approximately 29 and 26%. With soya flour panification is good, the crumb being more developed. Bread made with these substitutes retains more water than wheaten bread.—W. G.

Beef; Estimation of various forms of nitrogen in raw —, including the products of hydrolysis of some of the proteins. I. Hexone bases of some proteins of beef. II. Bromination of the hydrolysates of some proteins of beef. W. E. Thrnn and P. F. Trowbridge. J. Biol. Chem., 1918, 34, 343–353, 355–362.

THE results showing the distribution of nitrogen in the proteins of beef indicate that the proteins which are soluble in water are chemically distinct from those which are insoluble. The amount of bromine absorbed by a hydrolysed protein can be regarded as a measure of the amount of histidine which it contained. After sundry corrections for the amount of bromine absorbed by other amino-acids, etc., the proposed method gives results which approximate to those yielded by Van Slyke's method. (See also J. Chem. Soc., July, 1918.)

—H. W. B.

Grape-fruit (Citrus decumana) Some constituents of the American —. H. F. Zoller. J. Ind. Eng. Chem., 1918, 10, 364–374.

ANALYSES of grape-fruit (weight 430–770 grms.) showed that the peel contained 2.5 to 6.0 grms. per fruit of essential oils, consisting principally of limonene (90–92%) with small quantities of citral, α -pinene, geraniol, and linalool; also about 0.2 to 1.6 gm. of the glucoside naringin per fruit, and about 4 grms. of pectin. The pulp contains about 1.9 to 6.0 grms. of citric acid, 6.2 to 15 grms. of sucrose, and 8.6 to 19.6 grms. of dextrose per fruit. It is estimated that 10 to 15 galls. of proof spirit could be obtained from the sugars extracted from 1 ton of grape-fruit. (See also J. Chem. Soc., July, 1918.)—W. F. F.

Litchi nut (Litchi chinensis); The edible —. B. E. Read. J. Amer. Chem. Soc., 1918, 40, 817–822.

THE so-called Chinese hazel nut, *Litchi chinensis*, is known in several varieties, but those from Canton are almost spherical with a dull brick red

pericarp enclosing a sweet brown fleshy arillus which surrounds a glossy chestnut brown globular seed; It has long been used by the Chinese in medicine for reducing swellings, and is said to produce feverishness and bleeding at the nose if eaten excessively, but no iodine or saponin is present. It is practically fat free; the nitrogen-free extractive matter is composed mainly of simple sugars in which invert sugar predominates. Examination of the ash indicates a considerable content of the mineral salts needed in a well-balanced diet. A full bibliography on the grape fruit is included in the paper.—D. F. T.

Potatoes; Digestibility and food value of — in their different forms as fed, of potato-vinasses and of potato-haulms with farm animals. W. Völtz. Z. Spiritus-Ind., 1918, 41, 1–2. Z. angew. Chem., 1918, 31, Ref., 162.

DETAILS are given as to the food value of potato-vinasses and the preservation of raw and steamed potatoes by "souring." Metabolism experiments with sheep, milch cows, and a horse, feeding potato-haulms (in a dry condition and as silage) and potato "apples" are described.

Determination of chlorine in presence of organic matters (gastric juice, blood, milk, etc.). Sirot and Joret. See XXIII.

PATENT.

Nucleo-albumins in preserved eggs; Method for making soluble the —. N. Bendixen, London. Eng. Pat. 115,261, Apr. 30, 1917. (Appl. No. 6080 of 1917.)

THE nucleo-albumins of dried eggs are again rendered soluble in water by conversion into salts. When the eggs have been dried whole, a sample of the product is titrated with standard alkali, and the requisite quantity of alkali hydroxide, either in the dry state or in solution, is added to the bulk of the product. When added in solution, the product is again dried. When the whites have been dried and the yolks preserved in the liquid condition by means of boric acid, water is added to the dried whites and the preserved yolks mixed with the solution, which is then neutralised with alkali, and hydrogen peroxide added as a preservative.—L. A. C.

XIXB.—WATER PURIFICATION; SANITATION.

Sand filters; Theory of action of —. L. Minder. J. Gasbeleucht., 1918, 61, 56–57.

KISSKALT's view (J. Gasbeleucht., 1917, [9]) that the action of the sand filter in water purification is biological and due to the destruction of bacteria by other organisms is contested on the basis of experience at Zürich waterworks where the lake water is filtered in two stages through sand. The first retains most of the fresh-water planktons but allows some of the bacteria to pass. The bacteria are retained by the second filter and at the surface, so that at a depth of 10 cm. the number per c.c. has already fallen to one-tenth. Furthermore the retention of bacteria is satisfactory even when

there are considerable fluctuations in the number of bacteria in the water, and it is concluded that the process is mechanical rather than biological.

—H. J. H.

Snow and rain water: The sulphuric acid content of —. E. Küppers. *Z. angew. Chem.*, 1918, **31**, 74–76.

SULPHUR dioxide is so rapidly oxidised in the atmosphere that only sulphuric acid is found in snow and rain water. Sulphuric acid is rapidly deposited from the atmosphere on the exposed surfaces of trees and roofs. The sulphuric acid content of freshly fallen snow and rain depends on the proximity of industrial centres and the prevailing direction of the wind. An average figure for fresh snow in an industrial district is 15–20 mgrms. SO_3 per kilo. Fresh rain water collected in an open space in an industrial district contained 17–18 mgrms. SO_3 per litre; this is very much less than has been recorded by certain agricultural stations. Distilled water exposed to the air in an industrial district absorbed about 1.2 mgrm. SO_3 per 100 sq. m. in 24 hours.—J. F. B.

Antiseptic value of some essential oils. L. Cayel. *Comptes rend.*, 1918, **166**, 827–829.

FORTY-FIVE essential oils were examined in regard to the limit dose (in parts per 1000) necessary to be added to gelatin bouillon to prevent all microbial vegetation, even after seven months, when the plates were inoculated with a sewage effluent containing 9–11 million germs per c.c. The amounts required varied from 0.7 part per 1000 in the case of thyme oil up to over 150 parts per 1000 in the case of patchouli oil, the value, under similar conditions, for phenol being 5–6 parts per 1000.—W. G.

Fertilising value of activated [sewage] sludge. Nasmith and McKay. See XVI.

PATENTS.

Water: Process of softening —. H. Reiser. *Ges.m.b.H.*, Cologne - Braunsfeld, Germany. Eng. Pat. 112,127, Nov. 28, 1917. (Appl. No. 17,607 of 1917.) Under Int. Conv., Dec. 16, 1916.

The water is boiled to remove free and half-bound carbon dioxide before being treated with base-exchanging reagents, the formation of slimy deposits being thus prevented. Apparatus for this process includes a cooling apparatus between the boiling vessel and the tank containing the reagents, the untreated and the boiled water traversing this cooler in opposite directions. The cooling apparatus and the reagent tank are preferably sealed against admission of air.—C. A. M.

Waste waters [containing organic matter in solution]; Method of treating —. C. E. Cummings, Assignor to Eastern Tanners Glue Co., Gowanda, N.Y. U.S. Pat. 1,263,532, Apr. 23, 1918. Date of appl., Oct. 27, 1917.

CARBON dioxide is passed through the waste liquid to precipitate the organic matter, and the precipitate is removed.—L. A. C.

Sewage: Biological filter with oxidation for the destruction of bacteria, etc., in town and industrial —. Claros G.m.b.H. für Reinigung städtischer u. gewerblicher Abwässer, Dresden. Ger. Pat. 302,642, Nov. 9, 1915.

The filter is constructed of non-porous bodies of natural or artificial material, in the shape of crosses, built up in a regular order and separated by bars of square cross-section, so as to allow free access of air to the finely divided liquor which trickles through the filter.—H. J. H.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Arbutin; Detection of —. H. Salomon. *Ber. Dent. pharm. Ges.*, 1918, **28**, 138–139.

THE ferrie chloride test for bearberry extract and the similar test to be applied to the urine excreted after the consumption of bearberry leaf tea are not specific to arbutin, nor are the reducing tests with Fehling's solution or Nylander's reagent. In all these cases the reaction is probably due to other substances. (See also *J. Chem. Soc.*, July, 1918.)

—D. F. T.

Saponins [from mowrah seed]. L. Spiegel and A. Meyer. *Ber. Dent. pharm. Ges.*, 1918, **28**, 100–126.

THE saponin mowrin obtained from the seeds of *Bassia longifolia* (mowrah seeds) is a mixture of two substances (compare Moore, Sowton, Baker-Young and Webster, this J., 1909, 1061), the chief of which is more soluble in alcohol. This main ingredient has the formula $\text{C}_{42}\text{H}_{68}\text{O}_{25}$ and on hydrolysis yields levulose, arabinose, and mowric acid, the last of which is a mixture of a crystalline mowragenic acid, $\text{C}_{19}\text{H}_{28}\text{O}_8$, and an amorphous mowrageninic acid, $\text{C}_{15}\text{H}_{24}\text{O}_6$. By careful hydrolysis with dilute acetic acid an intermediate pentoside $\text{C}_{29}\text{H}_{50}\text{O}_{16}$ can be obtained. (See also *J. Chem. Soc.*, July, 1918.)—D. F. T.

Lecithin. II. Preparation of pure lecithin; composition and stability of lecithin cadmium chloride. P. A. Levene and C. J. West. *J. Biol. Chem.*, 1918, **34**, 175–186.

LECITHIN may be freed from accompanying traces of other phosphatides by transformation into its cadmium chloride compound, which is then recrystallised repeatedly from ethyl acetate and alcohol until free from amino-nitrogen. Subsequent treatment with ammonium carbonate liberates the pure lecithin. (See further *J. Chem. Soc.*, 1918, i., 288.)—H. W. B.

Essential oils: Constituents of —. *Betulol.* F. W. Semmler, K. G. Jonas, and W. Richter. *Ber.*, 1918, **51**, 417–424.

BETULOL, $\text{C}_{15}\text{H}_{24}\text{O}$, and its acetate were found by von Soden and Elze (this J., 1905, 634) in the oil of birch buds. From the results of a systematic investigation, the conclusion is drawn that betulol is a bicyclic, sesquiterpene alcohol of the terpene type. When treated with phosphorus pentachloride, part of the oil suffers ring closure under the influence of the hydrogen chloride liberated, the product being a mixture of bi- and tri-cyclic chlorides. If this is warmed with lime, a mixture of bicyclic dehydrobetulene, $\text{C}_{15}\text{H}_{22}$, and tricyclic betulol, $\text{C}_{15}\text{H}_{24}\text{O}$, is obtained, the latter crystallising in silky needles, m. pt. 147°–148° C. (See further *J. Chem. Soc.*, 1918, i., 301.)—J. C. W.

Chloretone (trichloro-tert-butyl alcohol); Method for detecting small quantities of — in aqueous solutions. T. B. Aldrich. *J. Biol. Chem.*, 1918, **34**, 263–267.

VERY small quantities of chloretone can be recognised by distilling with steam and boiling the distillate in a flask with reflux condenser, when needle crystals of chloretone form in the cooler part of the condenser. The presence of other organic solvents prevents the crystallisation. (See also *J. Chem. Soc.*, July, 1918.)—H. W. B.

Formamide; Preparation of —. A. Brann. J. Amer. Chem. Soc., 1918, 40, 793—796.

WORKING details are given for the preparation of formamide by the distillation of ammonium formate in a current of ammonia gas. By fractional redistillation under reduced pressure pure formamide can be obtained as a neutral viscous hygroscopic liquid which freezes at -2.25°C . (See also J. Chem. Soc., July, 1918.)—D. F. T.

Dehydrogenation. A new method. Synthesis of decacyclene, fluorocyclene, and chlorene, a green hydrocarbon. K. Dziewonski and S. Suknarowski. Ber., 1918, 51, 457—465.

When acenaphthene is heated with lead oxide in a sealed tube, decacyclene, $\text{C}_{30}\text{H}_{18}$, fluorocyclene, $\text{C}_{30}\text{H}_{16}\text{F}_2$, and small quantities of chlorene, $\text{C}_{30}\text{H}_{16}\text{Cl}_2$, crystallising in dark green scales and giving pure green solutions, are formed. By modifying the conditions slightly, either of the chief products can be obtained in better yields than hitherto experienced. (See further J. Chem. Soc., 1918, I., 296.)—J. C. W.

"Zingiberone" (methyl 3-methoxy-4-hydroxyphenylethyl ketone); Method of preparing —. H. Nomura, Sendai, Japan. U.S. Pat. 1,263,796, April 23, 1918. Date of appl., June 6, 1917.

ZINGIBERONE, a pungent principle of ginger root (*Zingiber officinale*) is prepared by condensing vanillin with acetone in the presence of aqueous caustic soda with formation of vanillylideneacetone, and reducing this by means of hydrogen in the presence of platinum black. (See also this J., 1917, 1062.)—D. F. T.

Ketones of the thiophen series; Manufacture of —. W. Steinkopf, Berlin-Halensee. Ger. Pat. 302,838, Oct. 8, 1916. Addition to Ger. Pat. 297,203 (this J., 1917, 638).

ORGANIC acid anhydrides may be used instead of their chlorides.—J. C. W.

Lecithin from plant substances; Process for obtaining —. C. F. Hildebrandt, Hamburg. Ger. Pat. 304,889, June 25, 1914.

LECITHIN is obtained by the usual extraction processes from the powdery substance occurring on the underside of the shells of leguminous or oleaginous fruits or of the husks of corn. This substance is much richer in lecithin than the whole fruit; e.g., peas contain about 1% lecithin, maize only $\frac{1}{4}\%$, the meal from the shells containing about 3% in each case.—B. V. S.

Alkaloids of cinchona bark; Preparation of hydrogenated products of the total —. Chem. Werke Grenzach A.-G., Grenzach. Ger. Pat. 301,910, Aug. 12, 1913.

THE impure drug obtained by the usual technical methods, or the ordinary extract of cinchona bark is treated with hydrogen in the presence of palladium. From the resulting fatty extract easily soluble crystallisable substances are obtained.

—B. V. S.

1 - Phenyl - 2,3 - dimethyl - 4 - diallylamino - 5 - pyrazolone; Preparation of —. Ges. für Chem. Ind. in Basel. Ger. Pat. 304,983, Apr. 14, 1916.

1 - PHENYL - 2,3 - DIMETHYL - 4 - AMINOPYRAZOLONE is treated in the warm with alkyl halides, conveniently in the presence of a solvent or diluent and of a substance capable of neutralising the resulting acid. 1 - Phenyl - 2,3 - dimethyl - 4 - diallylamino - 5 - pyrazolone obtained by this method is a stronger antipyretic than its well known dimethylamino-analogue, and possesses a more prolonged action although without increased toxicity; it also has a marked narcotic effect which is not shared to any appreciable extent by the dimethylamino-compound.

—D. F. T.

Extracts of drugs; Preservation of —. Knoll und Co., Ludwigshafen. Ger. Pat. 305,328, Dec. 14, 1915.

THE extracts or solutions of such extracts are treated with glycerol and camphor or a camphor substitute such as synthetic camphor. Solutions which have received this treatment, digitalis extracts in particular, resist the development of moulds and bacteria and therefore remain of use for injection purposes even after having been exposed to the air.—D. F. T.

Alkylselenylureas; Preparation of —. Chem. Fabr. von Heyden, A.-G. Ger. Pat. (A) 305,262, and (B) 305,263, May 27, 1915.

(A) THE products obtained by the action of hydrogen selenide on an alkyl cyanamide, e.g., allylcyanamide, in contrast to phenylselenylurea possess marked therapeutic effect, especially towards cancerous diseases; they are particularly valuable as intermediate products to their more stable and similarly active additive compounds with the alkyl halides. (B) The additive compounds of the alkylselenylureas with the alkyl halides probably possess the constitution $\text{NH}_2\text{C}(\text{NHR})\text{SeR}$ where R represents an alkyl radicle; the selenium is more firmly attached than in the corresponding selenylureas and as the compounds are more stable towards light and more soluble in water they are more convenient for injection.—D. F. T.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENTS.

Photographic emulsions; Preparation of —. W. Scheffer, Berlin-Wilmersdorf. Ger. Pat. 304,737, Dec. 17, 1916.

THE light-sensitive salts are produced as very fine-grained precipitates by allowing the reacting solutions to come into contact at a dialysing membrane. The solutions may be at different temperatures and pressures, and two or more dialysing membranes may be used.—B. V. S.

Process and apparatus for the separation of metals. Ger. Pat. 302,279. See X.

XXII.—EXPLOSIVES; MATCHES.

Silver acetylide. J. Eggert. Chem.-Zeit. 1918, 42, 199—200. (See also Ber., 1918, 51, 454.)

THE noise accompanying explosive decomposition is due to sudden alterations in the gaseous pressure occurring with a velocity of the order of that of sound. The acetylides of the heavy metals, e.g., silver acetylide, in decomposing, might be expected to give rise to carbon and metal only and therefore the explosion should be quiet except for the sudden disturbance in the surrounding air. However silver acetylide, especially if prepared from a solution of silver nitrate in aqueous nitric acid, explodes with great violence and noise even in a vacuum, whereas with a product precipitated from an ammoniacal solution of silver nitrate the explosion is much milder. The explanation of the vigour of the explosion and of the difference between the behaviour of the two varieties is to be found in the fact that the explosion does give rise to gaseous products, the "acid" variety yielding 17.2 c.c. of gas (N.T.P.) per 0.1 grm. of substance, whilst the "ammonia" variety yields only approximately one-tenth of this amount. The gaseous products consist of water vapour, hydrogen, oxides of carbon, and methane, together with oxides of nitrogen in the case of the "acid variety"; these must be due to the presence of occluded silver nitrate and silver oxide respectively in the "acid" and "ammonia" products. The latter variety is obtained purer, the lower the concentration of the silver and the greater the proportion of the ammonia. The disruptive power of "acid" silver acetylide is greater than that of silver fulminate but less than that of silver azide, the difference being attributed to difference in the velocities of detonation.—D. F. T.

PATENTS.

Explosives. A. Scgay. Ware, Herts. Eng. Pat. 113,083, Mar. 15, 1917. (Appl. No. 3812 of 1917.) Under Int. Conv., Aug. 17, 1916.

In explosives of the type composed of ammonium nitrate, trinitrotoluene, and calcium silicide, the proportion of the last-named ingredient is increased up to an amount such that, once the metal is oxidised, the whole of the carbon is burnt only to carbon monoxide, and only half the hydrogen to water. For example, with a mixture of ammonium nitrate 66, tetranitromethylaniline, or any explosive which may be detonated by itself, 7, and calcium silicide 27%, the excess of calcium silicide results in a more powerful explosive, and one which can be advantageously compressed to a greater degree, whereby it is made less hygroscopic, and becomes hard enough to handle easily. When the proportion of ammonium nitrate is high enough to cause the complete oxidation of the calcium silicide and to burn all the carbon and hydrogen to carbon dioxide and water respectively, the mixture will not explode satisfactorily if compressed so that the specific gravity is above 1.25, but an explosive of the composition given above may, on the other hand, be compressed to a specific gravity of 1.45 or even higher.—T. St.

Soap [for removing stains caused by nitro compounds]. Eng. Pat. 115,110. See XII.

XXIII.—ANALYSIS.

Ultra-filters; New and simple —. Ostwald. Kolloid Zeits., 1918, 22, 72—76.

SIMPLE forms of apparatus for the filtration of colloidal solutions are described. An ordinary funnel or a Büchner funnel may be employed if the filter paper is treated *in situ* with a 2%

collodion solution and certain precautions are observed in the fitting up of the apparatus. The best results, considered with reference to the speed of filtration, were obtained with an ultra-filter prepared by similar treatment of a Schleicher-Schüll Filtrierhut No. 577. A number of colloidal solutions of widely divergent character have been subjected to ultra-filtration in the apparatus described and the results obtained in each case are recorded.—H. M. D.

Gravimetric analysis; Contributions to —. L. W. Winkler. Z. angew. Chem., 1918, 31, 101—103.

V. *Determination of chlorides.* 100 c.c. of the cold solution is treated with 5 c.c. of N/1 nitric acid (or in presence of ferric salts, 10—20 c.c.) and a moderate excess of N/1 silver nitrate solution. The mixture is allowed to stand for one hour and then heated to boiling. After 24 hours the clear liquid is decanted through a plug of cotton wool in a "Kelch funnel." The clotted precipitate in the beaker is broken up with a very small quill in the first portion of the wash water and finally transferred to the filter. It is washed with 50 c.c. of cold water containing 2—3 drops of nitric acid and then with 50 c.c. containing a few drops of acetic acid. Pure water gives a cloudy filtrate. The precipitate is sucked dry with the pump and dried at 122° C. Small corrections depending on the weight of the precipitate are applied, e.g., -0.8 mgrm. for 1 grm., -0.1 mgrm. for 0.4 grm., and +0.2 mgrm. for 0.2 grm. and less. The results are accurate in presence of ammonium, alkali, alkaline-earth, magnesium, zinc, copper, manganese, aluminium, and ferric salts, but not in presence of mercury salts.

VI. *Determination of bromides.* The details are similar to those given for chlorides; the correction values are slightly smaller.

VII. *Determination of iodides.* The nitric acid is added half an hour after the silver nitrate; the correction values are -0.2 mgrm. for 1 grm., +0.3 mgrm. for 0.4 grm., and +0.5 mgrm. for 0.2 grm. of precipitate. Iodides may also be determined as palladium iodide. The procedure is varied according to the amount of chloride present. With iodides in excess, the neutral solution is diluted so that 100 c.c. will give about 0.1 grm. of precipitate; 1.0 grm. of sodium chloride is added and 10 c.c. of palladium chloride solution (0.5 grm. of palladium converted into chloride and dissolved in 10 c.c. of 10% hydrochloric acid, mixed with 1 c.c. of alcohol, and diluted to 100 c.c.). The mixture is gently boiled until the precipitate becomes granular, filtered off the next day, washed with 100 c.c. of cold water, and dried at 122° C. If the quantity of iodide is small, 100 c.c. of the solution acidified with hydrochloric acid is treated with 1 c.c. of palladium chloride and left with occasional shaking for 1—2 days. The flocculent precipitate is collected as before. The presence of bromides interferes with the accuracy, and, if considerable, the method cannot be used.—J. F. B.

Metals of the group soluble in ammonia; Separation of the —. A. Carnot. Ann. Chim. Analyt., 1918, 23, 93—97.

Copper and zinc. The metals are weighed together as oxides and the latter are then heated at bright redness for about 45 mins. in a current of hydrogen; the zinc is reduced and volatilises completely, leaving a residue of metallic copper which is weighed. *Copper, zinc, and nickel.* The dilute hydrochloric acid solution of the three metals is heated to boiling and treated with sodium thio-sulphate; copper is thus precipitated as sulphide and is separated by filtration. The zinc and nickel in the filtrate are precipitated as carbonates, ignited, and the zinc volatilised by heating in a

current of hydrogen. **Zinc and cadmium.** The metals are dissolved in nitric acid, the solution evaporated, the residue dissolved in dilute nitric acid, the solution is diluted and rendered alkaline with sodium carbonate, and sufficient ammonium carbonate is added to dissolve the zinc carbonate. The mixture is boiled until all free ammonia has been expelled, the cadmium carbonate is collected on a filter, and the zinc is determined in the filtrate as sulphide. To remove all the zinc, the cadmium carbonate should be dissolved and re-precipitated. **Copper, zinc, cadmium, nickel, and cobalt.** Copper is separated as sulphide by treating the hydrochloric acid solution of the metals with sodium thiosulphate (see above). The solution is then nearly neutralised, a large excess of ammonium oxalate is added, and the zinc is precipitated by treating the hot solution with hydrogen sulphide. Cadmium, if present, is also precipitated, and may be separated from the zinc as described. Nickel and cobalt are precipitated together as sulphides by rendering the solution slightly ammoniacal, heating it at 100° C., and adding sodium sulphide; they are then separated from one another by known methods.—W. P. S.

Copper; Estimation of — as copper oxide after previous precipitation as thiocyanate. G. Fenner and J. Forschmann. *Chem.-Zeit.*, 1918, 42, 205—206.

THE advantage of the thiocyanate precipitation of copper over the hydrogen sulphide method may be increased by the direct conversion of the cuprous thiocyanate into cupric oxide. The copper thiocyanate precipitation is not interfered with by the presence of iron, manganese, zinc, cobalt, nickel, arsenic, or bismuth; antimony and tin are previously removed together with lead when the latter is converted into lead sulphate. The accuracy of the thiocyanate precipitation is not affected by a twenty-fold excess of reagent, but the proportion of sulphurous acid or of ammonium sulphite should not be too great. By heating in a muffle at 800° C. the cuprous thiocyanate precipitate can be quantitatively converted into cupric oxide but, if desired, the alternative procedure may be adopted of dissolving the precipitate in a mixture of nitric and sulphuric acids and separating the copper electrolytically; with small quantities of copper this alternative solution method may be modified by applying a colorimetric method of estimation. (See also *J. Chem. Soc.*, July, 1918.)—D. F. T.

Strontium; Determination of —. L. W. Winkler. *Z. angew. Chem.*, 1918, 31, 80 and 83—84.

For the determination of strontium as sulphate, 100 c.c. of a neutral solution containing 0.5 gm. of strontium salt is acidified with 1 c.c. of acetic acid and heated to boiling, when 10 c.c. of a 10% solution of sodium sulphate is added. Heating is continued until the precipitate has become powdery, when it is allowed to stand overnight. The precipitate is transferred to a Gooch crucible, washed with 50 c.c. of saturated strontium sulphate solution, and weighed after drying at 132° C. If the filtrate is required further, alcohol is used for washing. Low results are obtained in the presence of many salts and of nitric and hydrochloric acids. For determination as oxalate, precipitation is effected as above but with 10% potassium oxalate solution. After standing overnight the precipitate is washed with saturated strontium oxalate solution. It may be dried at 100° C. for 2 hours and weighed as $\text{SrC}_2\text{O}_4 \cdot \text{H}_2\text{O}$, or at 132° C. for 6 hours and weighed as SrC_2O_4 . Other salts, especially magnesium chloride interfere. Strontium may be determined as carbonate by adding 1.0 gm. of potassium nitrate and 10 c.c. of 10% sodium carbonate solu-

tion to a boiling solution of not more than 0.5 gm. of strontium salt in 100 c.c. of solution. Next day the precipitate is washed with 50 c.c. of saturated strontium carbonate solution, dried at 132° C., and weighed. Owing to incomplete loss of carbon dioxide the precipitate cannot be weighed as oxide after ignition. It is most convenient and accurate to estimate strontium as oxalate.—H. J. II.
